I. INTRODUCTION

This component of Milliman & Robertson's examination of the ratemaking procedure used by the National Council on Compensation Insurance (NCCI) discusses the methodology NCCI uses to incorporate expenses in the ratemaking process, evaluates the appropriateness of that methodology, and suggests improvements.

A critical consideration in the development of a final rate is the expense factor. Is it appropriate to use an average, a budgeted amount, or a factor that reflects individual company experience? All of these questions have been raised at one time or another by various regulators. As the Request for Proposal (RFP) makes clear, the NCCI treatment of expenses is complicated by many factors. These factors are all, in a sense, interrelated in how they impact the final workers compensation premiums paid by insureds.

Some issues are thought to be of much higher priority than others, especially the extent to which the actual expenses conform to the assumptions contained in the rate, and the cost-benefits of collecting allocated loss adjustment expenses (ALAE) on a unit basis. All of the issues, except for ALAE on a unit basis, rely heavily on the quality and interpretation of the expense data compiled by NCCI. The two-pronged approach called for in the RFP, i.e., independent assessments of both the data quality and ratemaking methodology for expenses, should provide a thorough analysis of these issues. This section of the report analyzes the ratemaking methodology for expenses.

The NCCI expense items are typically divided into the following items:

- General expenses,
- Production expenses (commission, brokerage and other acquisition expenses),
- Taxes, and
- Loss Adjustment Expenses (LAE).

EXPENSES

Loss Adjustment Expenses (LAE) can be further subdivided into two components: ALAE and Unallocated Loss Adjustment Expenses (ULAE). ALAE items are directly traceable (assignable) to a particular claim file. ULAE consist of the overhead classes of expenses resulting from the operation of a claim department and the processing of claim transactions. ULAE items are not directly traceable to a particular claim file. Currently, the definition of ULAE and ALAE will vary from company to company.

NCCI does not currently subdivide LAE into ALAE and ULAE in establishing manual rates or loss plus LAE costs (in loss cost states). NCCI derives a combined ALAE and ULAE loading which is multiplied by loss costs to derive manual rates.

Section II of this report summarizes our conclusions, recommendations and observations. Section III describes the NCCI expense methodology. The remaining Sections (IV through IX) respond to the objectives of the Florida Insurance Department's RFP, which covers the following areas:

Objective 2a: Evaluation of the NCCI Expense Methodology

Objective 2b: Costs and Benefits of Collecting ALAE by Claim

Objective 2c: State Specific Expense Issues

Objective 2d: Budgeted Approach to Acquisition Expenses

Objective 2e: Justification for Dual Expense Discounts

Objective 2f: Equity of Premium Discounts Programs and Expense Constants

EXPENSES

II. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

The following is a summary of our conclusions and recommendations. These recommendations assume that NCCI continues to prepare manual rate filings (instead of or in addition to loss cost filings) or that NCCI continues to publish expense analyses for consideration by individual insurers in developing their own expense provisions.

Objective 2a: Evaluation of the NCCI Expense Methodology

NCCI expense provisions have overstated the actual amount of expenses incurred by the companies. This observation is apparent in both general and production expenses. The effect of this overstatement on final policyholders costs depends on many factors including the adequacy of loss cost estimates and the effect of individual state regulatory actions.

NCCI expense analysis procedures should be improved so that expense provisions more closely relate to actual expenses. To the extent that verifiable trends are apparent, NCCI should reflect them. In particular, we have the following comments regarding the recent promulgation of expense provisions for general expenses, production expenses, tax provisions, and loss adjustment expenses:

General Expenses

- The current NCCI general expense methodology involves assumptions which tend to produce indications higher than actual average expense amounts incurred. For example, the current negative (downward) general expense trend is not projected to the period when rates will be in effect even though the average discount for general expenses underlying the premium discount plan is trended to the period when rates will be in effect. The general expense variable loading component has decreased from 8.34% in calendar year 1984 to 6.75% in calendar year 1989. We agree with the NCCI adjustment for the average discount underlying the premium discount plan; however, we

EXPENSES

recommend that premium and expenses should also be trended to the period when rates will be in effect (Section IV, Page 21-22).

- NCCI compares general expenses to net earned premium. We recommend that NCCI compare general expenses to direct earned premium (Section IV, Page 22).
- The NCCI Actuarial Committee (Committee) in October, 1990 recommended a general expense provision of 6.7%. Alternative methods, which adjust premium and expenses to the period when rates will be in effect, resulted in indicated direct general expense provisions lower than the NCCI provision of 6.7%. The difference arises for reasons that include the fact that the recent average countrywide rate increases have exceeded the inflationary factors affecting general expenses (Section IV, Page 28-29).
- NCCI should combine the expense experience of stock and mutual companies in establishing general expense indications. Based on recent experience, this is not expected to have a material impact on the selected expense provisions. (Section IV, Page 30).

Production Expenses

- NCCI does not collect data useful to the analysis of the NCCI production expense provision of 15% for the first \$5,000 of standard premium. The expense study by size of risk should incorporate all production expenses (i.e., commission, brokerage and other acquisition expenses) in order to determine the appropriateness of the expense gradations. Previously, the study was limited to a review of other acquisition expenses only (Section IV, Page 30).
- We recommend that NCCI review production expenses annually, as it does for other expenses, in establishing production expense provisions (Section IV, Page 30).

EXPENSES

- The budgeted first \$5,000 production allowance of 15.0% exceeds the actual amount projected to be expended by stock insurers, for combined voluntary and involuntary risks. The amount projected to be expended by stock insurers varied around 14.0% for calendar years 1985 through 1988 and is estimated at 13.0% for 1989. Most, if not all of this difference, may be attributable to the lower commissions incurred on involuntary risks. This analysis assumes that the NCCI production expense gradations are appropriate (Section IV, Pages 30-31).
- The all size of risk analysis, indicates that the production allowance in the rates has exceeded the actual amount expended by stock insurers by 2.0 to 3.0 points of standard premium for calendar years 1986 to 1989. Based on our analysis, it appears that 1.5 to 2.0 points of this difference may be explained by the lower commission levels on involuntary business. The remaining difference is due to: (1) the expense gradations and (2) the fact that some stock carriers use the non-stock premium discount table (Section VII, Pages 65-66).

Tax Provisions

- With regard to premium tax provisions, the proper methodology to incorporate premium tax in the final rate will depend upon the interpretation of the NCCI final rate. If the NCCI rate is intended to be the average rate for the average company, then the tax provision should be based on the average taxes collected. If the NCCI rate is a benchmark for a specified type of insurer then the premium tax provision in the rate should be the tax rate appropriate for that type of insurer (Section IV, Page 31).
- We agree with the NCCI treatment of the other tax provisions (excluding premium tax). However, we recommend that the detailed study of miscellaneous taxes be updated more often than was true in the recent past, once every ten years. NCCI is currently in the process of updating the 1981 detailed study of miscellaneous taxes (Section IV, Page 32).

EXPENSES

Loss Adjustment Expenses

- Historically, NCCI has based their LAE provision on a review of net and direct calendar year experience. Based on the calendar year data, in October, 1990 NCCI recommended that an LAE provision of 12.0% be utilized in rate filings with an average effective date of July 1, 1991 and an average accident date of January 1, 1992 (Section III, Page 18).
- In order to enhance the Committee's ability to analyze LAE, NCCI issued a special call to collect accident year direct paid and outstanding: losses; ALAE; and ULAE. The first call was issued to collect data as of year-end 1988. The NCCI staff reviewed the accident year experience at the February, 1991 meeting and recommended that the 12.0% provision be maintained, although a higher provision was indicated based on the NCCI's analysis, due to the lack of historical experience. The data call was only available at year-end 1988 and 1989. However, the Committee, after reviewing the special call data, voted to increase the LAE provision from 12.0% to 12.5% based on the NCCI projected LAE to loss ratio by accident year (Section IV, Page 32-34).
- We recommend that NCCI rely on the special call data (direct experience) by accident year in establishing the LAE provision. Based on reviewing the special call data, a LAE provision between 12.0% and 12.5% of losses is indicated (Section IV, Page 33-34).

Objective 2b: Cost and Benefit of Collecting ALAE by Claim

We recommend that NCCI collect Allocated Loss Adjustment Expense (ALAE) experience by claim and that ALAE be treated like losses for ratemaking purposes. The rationale for this recommendation includes:

1. ALAE has grown to be a more and more significant element of workers compensation costs, increasing from 4.5% of losses for accident year 1980 to

EXPENSES

5.8% in accident year 1989 based on the individual company's estimates from a NCCI call (Section V, Page 42).

2. Treating ALAE like losses in the ratemaking process will result in more accurate rates by state, industry group, and classification.
3. By collecting ALAE data on retrospective and residual market policies it will be possible to reimburse insurers for actual amounts paid in claim defense, rather than reimbursing the insurers based on an average expense provision.
4. The perceived trend in the LAE ratio will be better understood if ULAE is separate from ALAE.

We worked with NCCI to design a survey to sample small, medium, and large companies to determine the cost of collecting ALAE by claim. The cost estimate, .05% of workers compensation premium for insurers and \$1.4 million for NCCI, is sufficiently low in relation to the benefit that we recommend ALAE be collected by claim effective January 1, 1993. However, a transition program may be appropriate for companies which will incur a high relative cost (Section V, Page 39-41).

The NCCI Actuarial Committee recommended that ALAE be collected by claim and utilized like losses in ratemaking and recommended a January 1, 1993 effective date. The NCCI Board will vote on the ALAE collection issue next year. In addition, a uniform definition of ALAE is required and Exhibit 23 displays the NCCI proposed definition. We concur with the Committee's recommendations.

Collecting ALAE by claim will require changes to the unit statistical reports and the financial calls.

In addition, NCCI will need to develop a procedure to establish a separate ULAE provision. One possibility is to develop a ratio of ULAE to loss plus ALAE by analyzing the special call by accident year. Thus a countrywide ULAE provision could be estimated by accident year and trended if appropriate (Section IV, Page 34).

EXPENSES

The treatment of ALAE and ULAE expenses in loss cost states will need to reflect differences in statute and regulation by state. We recommend that loss costs include ALAE and ULAE when not prohibited by statute or regulation.

Objective 2c: State Specific Expense Issues

The NAIC RFP asked M&R to address the following question - "Should expense loadings for an individual state be tempered when that state experiences a rate increase larger than the countrywide average." While we concluded that tempering is not appropriate, the analysis led to valuable research in the area of state-specific expense levels.

The issue of tempering expense provisions is more correctly viewed as the issue of whether expense ratios should vary by state, (i.e., the expense ratio in a state should be the same whether the state rates rise 40% more than the countrywide average in one step or several steps). NCCI data suggests that there are variations from state to state and we recommend that additional research be performed to determine the appropriateness of varying expense levels by state. To the extent that verifiable differences exist by state, NCCI should reflect state expense levels in the ratemaking process (Section VI, Page 56-57).

Our analysis of tempering for large rate increases is contained in Section VI. The following factors suggest that tempering expenses is not appropriate and that the current NCCI procedure is appropriate.

1. If expenses are reflected correctly on a countrywide basis, any adjustment for large rate increases will result in an inadequate countrywide expense provision.
2. The downward trend in general expense, noted above, is due in part to the level of rate increases implemented in the past.
3. If rates are deficient over a period of time, it is likely that expenses are also deficient.

EXPENSES

4. There are a number of factors to mediate the expense impact of a large rate increase in a state including the fact that more than 40% of the premium is from multi-state risks and the majority of the countrywide premium is generated from risks subject to the premium discount tables.

Objective 2d: Budgeted Approach to Acquisition Expenses

As mentioned previously based on our analysis, the first \$5,000 budgeted provision of 15.0% exceeds the actual amount expended by stock insurers for combined voluntary and involuntary risks. This analysis assumes that the NCCI production expense gradations are appropriate. NCCI should establish a production expense element based on actual experience rather than the budgetary approach by comparing direct production expenses to direct written premium. This will require that NCCI prepare an annual production expense review similar to the current general expense review. However, in order for NCCI to properly perform this review, the production allowances by size of risk need to be verified. Therefore, NCCI should collect all production expenses in the 1991 call for expenses by size of risk (Section VII, Page 66-67).

Objective 2e: Justification for Dual Expense Discounts

The rationale for separate premium discount tables for stock and non-stock insurers is based on the perceived difference in dividend payments between stock and mutual companies. The dividend differential between stock and mutual companies has largely disappeared in the past two years, but this coincided with significant decreases in profitability as presented in the Insurance Expense Exhibit. Stock and mutual company profitability, net of dividends to policyholders, appears similar. Since the profitability net of dividends to policyholders appears similar, the use of separate expense discount tables appears to be justified. However, NCCI should review mutual and stock expense experience by size of risk to confirm if the current tables are justified (Section VIII, Page 74).

EXPENSES

Objective 2f: Equity of Premium Discount Programs and Expense Constants

Based on data from the 1982 Expense Study, we measured the required dollars of general expense by size of risk and compared it to the general expense dollars generated by the discount tables and the expense constant. Based on this analysis, there are no significant biases by size of risk determinable from the 1982 general expense study by size of risk. However, we recommend that the expense study by size of risk be updated more often than every nine years. The most recent study was completed in 1984 based on 1982 expense experience. The NCCI Actuarial Committee has scheduled an update during 1992 based on calendar year 1991 expense experience. Several factors have changed since 1982 which could affect the distribution of expenses by size of risk including: average policy size, cost efficiencies and inflation (Section IX, Page 80-83).

In addition, we recommend that the 1991 commission and brokerage expenses by size of risk also be collected in 1992. This information is necessary to evaluate the production allowances by size of risk which, in turn, determine the premium discount provisions by standard premium division. NCCI is not planning on requesting that data (Section IX, Page 83).

EXPENSES

III. DESCRIPTION OF NCCI EXPENSE METHODOLOGY

A. Overview of NCCI Annual Expense Review

1. Data Utilized

NCCI utilizes the following data sources in establishing expense levels:

- Insurance Expense Exhibits (IEE).
- NCCI 1982 Study of Expenses by Size of Risk.
- NCCI call for ALAE and ULAE by accident year (Data call #19).
- Residual market servicing carrier expense reimbursement amounts and information on how those reimbursements are treated for IEE purposes.
- Distribution of policies by size (Data call #7).
- Company premium on a uniform rate level basis (the Designated Statistical Reporting Level).
- 1984 study of miscellaneous taxes.
- State and local premium tax laws.
- Special call for expenses by state (Data call #14).
- Consumer Price Index.

2. Staff Role

NCCI staff prepares an annual expense review package in October of each year. We have attached Exhibits 1 through 4 and 6 through 10 which are the key exhibits from the 1990 NCCI expense review. Based on the annual expense review, the NCCI staff

EXPENSES

recommends countrywide expense provisions for general expense and loss adjustment expenses. The NCCI Actuarial Committee (Committee) then reviews the staff's recommendations. The expense provisions approved by the Committee are incorporated in subsequent rate filings unless a state requires that state specific expense experience be used.

Production expense provisions are not routinely reviewed by staff or by the Committee. Production expenses are assumed to be a budgetary item and budgetary items are not generally reviewed. NCCI has not altered the budgetary production expense provisions since 1977.

The tax provision is established by NCCI staff without Committee review.

3. Expense Provisions

The NCCI expense program includes three elements: variable expense provisions for each type of expense that do not vary by size of risk, discount provisions by size of risk and an expense constant. The variable element and expense constant in the manual rate are intended to provide a sufficient expense provision for the first \$5,000 of premium. The premium discount by size of risk begins at \$5,000.

The October 1990 NCCI expense review resulted in the following recommended expense provisions to be included in 1991 rate filings.

- a. Variable expense components for the first \$5,000 of premium as follows:

General Expenses	6.7%
Production Expenses	15.0%
Taxes - Varies by State	4.2%*

* average

- b. An LAE provision of 12.0% of losses. The factor is intended to provide a sufficient provision for both ALAE and ULAE. The factor does not vary by size of risk, type of insured, or state.

EXPENSES

c. Premium discount programs as follows:

<u>Standard Premium Size Range</u>	<u>Stock Premium Discounts</u>	<u>Non-Stock Premium Discount</u>
First \$ 5,000	0.0%	0.0%
Next 95,000	10.9	3.5
Next 400,000	12.6	5.0
Over 500,000	14.4	7.0

The premium discount programs are based on reduced general expense and production expense components for the larger policy sizes. The different tables are based on the perceived dividend differential between stock and mutual companies.

d. An expense constant of \$140 consisting of the following elements:

EXPENSE CONSTANT	
<u>Item</u>	<u>Amount</u>
General Expenses	\$ 83.55
Production Expenses	47.35
Taxes	5.70
Profit	<u>3.40</u>
Total	\$140.00

Approximately 11% of the total general and production expense provision is collected through the expense constant.

The following four sections describe the NCCI staff procedure for developing general expense, production expense, LAE and tax provisions.

EXPENSES

B. NCCI Methodology for General Expenses

The components of the general expense provision are an expense constant, the variable provision used for the first \$5,000 of premium and the discounts from that variable provision applicable to higher premium amounts. The first two items are discussed below, and the discounts are discussed in Section IX.

1. Expense Constant

Exhibit 1 displays the calculation of the indicated expense constant from the October, 1990 review. The 1990 indicated expense constant is equal to the portion of the expense constant for general and production expenses from the 1982 study adjusted for inflation. Thus lines 1 and 2 are multiplied by line 3, the NCCI Expense Index (Index). Exhibit 2 displays the mix of expenses utilized in the Index. The inflation adjusted expense constant components are summed and loaded for profit and taxes by dividing the summed amount by one minus the profit and tax provision.

While the indicated expense constant based on the 1990 review is \$152.69, the Actuarial Committee recommended that the current \$140 expense constant be maintained. Exhibit 3 displays the approved expense constants and expense provisions which vary by state.

The expense constant provides approximately 20% of the general expense revenue. The size of the expense constant affects the equity of premium charges for insureds of different sizes, but it does not control the adequacy of the total general expense provision. If the larger expense constant, \$152.69 were recommended, then the variable provision would be reduced. The same total expense dollars would be collected through the rating plan. Section IX presents a further discussion on the equity issue.

2. General Expense - Variable Provision for First \$5,000

Exhibit 4 displays the general expense indications by calendar year for stock companies based on the October, 1990 expense review. The analysis is based on stock companies' IEE for calendar years 1984 through 1989. NCCI receives individual company IEE's and summarizes the IEE's.

EXPENSES

Row 1 of Exhibit 4 is the estimated net standard earned premium. The Committee utilizes Part III of the IEE and an estimate of schedule rating and carrier deviations (about 3% for 1989) to convert reported net earned premium to standard net earned premium at NCCI rate levels. Exhibit 5 displays the calculation of standard net earned premium for stock companies for calendar year 1988.

The standard premium is the premium before the following: retrospective rating adjustments, premium discount (expense graduation), schedule rating, and carrier deviations. Thus, Row 1 of Exhibit 4 is an estimate of the manual premium (i.e., the premium based on manual rates) times the average experience modification plus the expense constant. In states where NCCI files loss costs and not manual rates, company's premium level is converted to a theoretical NCCI manual rate level based on the NCCI standard expense provisions and the NCCI loss costs.

The expense constant offset, Row 2, is utilized to determine the premium dollars generated as a result of the expense constant assuming a \$140 expense constant. Row 3 is an estimate of the standard premium excluding the revenue from the expense constant, and Row 1 minus Row 3 is an estimate of the expense constant revenue assuming the \$140 expense constant.

Row 4 displays the general expenses for stock companies as reported in the IEE (Line 7 - Part II for Workers Compensation). Row 5 is the proportion of the expense constant revenue that is associated with general expenses. The factor to calculate the proportion is calculated in Exhibit 6 which displays the calculation of the expense constant revenue split between general and production expenses. The split is based on the 1982 expense by size of risk study.

Row 6 is the IEE general expenses less the expense constant revenue associated with general expenses. Therefore, Row 6 represents the amount of general expenses which will be loaded into the rates through the variable expense provision.

Some insurers record residual market general expense in ways which would distort the expense analysis. For example, a servicing carrier may record general expenses on residual market business as a direct general expense and the entire servicing carrier allowance as a negative general expense. The servicing carrier allowance, however,

EXPENSES

includes a provision for other acquisition and LAE as well as general expenses. NCCI will adjust for any distortion and this is presented in Row 7. Technical Appendix A discusses the servicing carrier adjustment in more detail.

The NCCI treatment of expenses in this regard aims at determining the appropriate general expense provision for voluntary and residual market insureds combined. NCCI does not attempt to determine the differential, if any, between the two groups of policyholders unless required by a specific state.

The adjustment for the average discount for general expenses underlying the premium discount plan (Line 8) is needed to convert the observed expense provision, which is an average provision for all premium sizes, to a provision for the first \$5,000 of premium. The calculation for the average discount is displayed on Exhibit 7. However, the exhibit fails to display the source of all the underlying inputs. The premium distribution by size of risk and the general expense gradations derived from the 1982 study of expenses by size of risk are used to derive the average discount by year. Insurers publish an average premium discount in the IEE, but NCCI believes its own calculation is more reliable. This average discount is trended to a January 1, 1992 premium distribution level. January 1, 1992 is the midpoint of premium earned for policies effective during 1991.

Some states mandate that state specific expense experience be utilized in establishing expense provisions. In these states, NCCI utilizes the special call for expenses by state. Section VI discusses the issues involved in using varying expense levels by state.

C. NCCI Methodology for Production Expenses

Production expense includes both commission and brokerage expenses and other acquisition expenses.

The first \$5,000 of standard premium incorporates a 15% production expense provision. The percentage provision decreases as the premium size increases. The following table displays the production allowances underlying the stock premium discount table.

EXPENSES

<u>Division of Premium</u>	<u>Stock Production Expense Allowance</u>
First \$ 5,000	15.00%
Next 95,000	7.50
Next 400,000	6.00
Over 500,000	6.00

In addition, \$47.35 per policy of the \$140.00 per policy expense constant is intended to provide for the fixed component of production costs (i.e., other acquisition expenses).

There is no NCCI documentation for the production discount provisions. The only production expense information obtained with the 1982 study of expenses by size of risk related to other acquisition expenses. Commission and brokerage expenses were not incorporated in the study and no other NCCI data call collects commission and brokerage expenses by size of risk.

The Committee selected the above production expense provisions as reasonable without a detailed study. NCCI refers to this as the budgetary basis.

D. NCCI Methodology for Loss Adjustment Expenses

LAE is incorporated into manual rates as a percentage factor applied to losses. As mentioned, NCCI currently utilizes a combined factor to reflect ALAE and ULAE. The Committee's recommended LAE provision is a countrywide factor which does not vary by state, industry group, or classification; however, there are state exceptions which are shown in Exhibit 3. NCCI reviews the relationship between direct LAE and direct losses as reported in the IEE for the most recent 3 and 6 calendar year periods for stock and mutual companies combined. In addition, NCCI reviews a longer term (1964-1989) history of the ratios net of reinsurance.

Exhibits 8 and 9 display the direct and net ratios for the most recent 3 calendar years from the October, 1990 review. Exhibit 10 displays the historical net and direct

EXPENSES

ratios. The average direct ratio for the most recent 3 years is 11.83% and the net ratio is 13.62%. Based on the October, 1990 review NCCI selected a LAE provision of 12.00%.

It appears that NCCI has relied more heavily on the direct ratios in establishing the LAE provision, although NCCI does not state that they rely more on direct or net ratios. Rating organizations generally use direct loss and expense experience for ratemaking calculations for casualty lines of insurance. NCCI stated that the net ratios are higher than direct ratios for reasons that include the following:

- Incomplete data because some reinsurance-only carriers may be excluded.
- Non-proportional expense sharing on some reinsurance agreements.
- Different accounting procedures for different companies.
- Direct incurred but not reported (IBNR) reserves are larger than net IBNR.

In some state rate filings, NCCI will display only the net LAE calendar year ratios (higher ratios).

Historically, NCCI evaluated calendar year (i.e., IEE) LAE ratios to select the LAE expense provision. To enhance the Committee's ability to analyze LAE, NCCI collected accident year direct paid and outstanding losses, ALAE, and ULAE for accident years 1980-1989. Exhibit 11 displays the analysis of this information for the February 20, 1991 Actuarial Committee Meeting. Based on that information NCCI staff recommended that the 12.0% provision be maintained. However, the Committee revised the LAE provision to 12.5% based on a perceived upward trend in the LAE ratio and the experience for recent accident years.

The incurred accident LAE ratios (Exhibit 11, Column 11) are based on individual company assignment of ALAE and ULAE payments and reserves by accident year. NCCI requested that companies utilize a procedure similar to the procedure used for

EXPENSES

allocating ULAE in Schedule P. Chapter IV discusses the issues involved in allocating ULAE to accident year.

Column (13) of Exhibit 11 displays the indicated LAE provision based on a NCCI projection method and Column (11) displays the individual company's estimate of the LAE ratio. Assuming no trend, Column (13) supports the 12.5% LAE provision; however, Column (11) supports the 12.0% provision (assuming the 1989 indication is an outlier). Our trend analysis on the company's estimate (Column (11)) indicates a trended LAE ratio of 12.6% as of January 1, 1992; however, the trended LAE ratio is only 12.1% if the accident year 1989 observation is excluded.

Page 14 of the statutory annual statement will display incurred ALAE and ULAE as of December 31, 1991. NCCI does not plan on utilizing this information in determining rate levels. NCCI stated that the page 14 data has the following limitations:

1. Different companies may use different definitions of ALAE;
2. The accident year ratio of ALAE to incurred loss is more appropriate for ratemaking than the calendar year ratio (page 14 displays calendar year data); and
3. ULAE cannot usually be identified by state.

E. NCCI Methodology for Tax Provisions

The tax provision has two components as follows: state and local insurance taxes, and miscellaneous taxes which include Insurance Department licenses and fees, payroll taxes, and all other taxes - excluding state and local insurance taxes.

The tax provision for state and local insurance premium taxes is based on the statutory provision and is state specific. Some states have different premium tax levels for domestic and foreign (out-of-state) insurers. NCCI selects the foreign insurer tax rate for its premium tax provision. Thus, NCCI does not utilize the actual collected workers compensation taxes in a state. Generally, this is the only state specific element in the NCCI expense provision.

EXPENSES

The treatment of assessments for second injury funds, guaranty funds and other funds in the ratemaking formula varies depending on the nature of the assessment. The assessments that are collected on the basis of premium are treated in a similar manner to premium taxes in the determination of manual rates. In the case where the Compensation Law specifies that, in connection with certain types of injury, a specified amount shall be paid into a special fund (e.g., second injury fund) and that such amounts are in addition to the compensation payable to the injured worker or his dependents, then the combined total amount is reported as incurred indemnity losses. The assessments based on premium writings or total losses are included in manual rates through a flat loading to the classification losses and Financial Data Calls. The assessments are estimated based on the experience in the most recent year available.

The miscellaneous tax allowance is a countrywide value based on a 1981 special call for compensation tax payments. NCCI updated the value in 1984 by considering the effects of changes in the social security tax rates and payroll base.

EXPENSES

IV. OBJECTIVE 2a: EVALUATION OF THE NCCI EXPENSE METHODOLOGY

This section addresses the following objective of the Request for Proposal (RFP):

Objective (2a) Expenses - Does the current NCCI expense Methodology tend to load more or less expenses in the overall rate level than are actually expended by insurers using stock discounts in NCCI states. If there are biases or inaccuracies, what is their source and their effect?

A. General Expenses

1. Stock Company Expense Experience

The NCCI annual general expense review in October of 1990 reviewed stock companies' IEE expenses for calendar years 1984-1989. The expense indications (ratios of general expenses to net earned premium) from this review are incorporated in 1991 rate filings with an average effective date of July 1, 1991 and an average premium earned date of January 1, 1992.

The raw indications from the NCCI October, 1990 expense review are displayed in the following table:

1990 Annual Expense Review
General Expense Indications For Stock Companies
(\$140 Expense Constant)

<u>Calendar Year</u>					
<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>
8.34%	7.43%	7.15%	7.10%	6.87%	6.75%

Based on this expense review, NCCI selected a variable general expense provision of 6.7%. NCCI does not have a specific formula for determining the expense provision. NCCI selects a value based upon reviewing the above table and supporting data.

EXPENSES

The 1984-1989 general expense levels relative to net earned premium display a decreasing trend. NCCI does not project the expense trend to a January 1, 1992 level. In addition, NCCI compares general expenses to net earned premium. We recommend that NCCI compare general expenses to direct earned premium. The following table displays the general expense ratios relative to direct earned premium.

<u>Calendar Year</u>			
<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>
6.54%	6.55%	6.54%	6.34%

The attached Exhibit 12 displays the detailed calculation. The direct indications are not displayed for calendar years 1984 and 1985 as the direct experience is not available in a summarized format for these years. NCCI's use of net instead of direct premium results in a higher general expense indication than the use of direct earned premium. We believe the net experience is not appropriate as NCCI manual rates and loss costs are intended to provide a sufficient expense provision for the direct insurer.

In addition, the general expense trend should be reflected by estimating the general expense levels for the period during which rates will be in effect. This can be accomplished by projecting expenses and premium to the average date on which policies are earned - January 1, 1992.

We utilized three methodologies to adjust expenses and premium to a January 1, 1992 level. All three of these models adjust premium to a current rate level and adjust expenses to a prospective cost level. The primary difference between the models relates to the amount of expense trend assumed. We are not proposing that NCCI adopt a specific model. However, we believe that NCCI should utilize a model or models that reflect trends in the data. The following three models reflect trends in the underlying data to varying degrees and we developed a test to determine how well the models have performed historically. In addition, all of the models are

EXPENSES

sensitive to the number of years analyzed. We believe that NCCI should have discretion in selecting the experience period in order to appropriately reflect trends.

The first model (Model 1) adjusts expenses to a January 1, 1992 level by utilizing the NCCI Expense Index (Index) which is derived on Exhibit 2. Exhibit 13 displays the expense index and trend based on calendar years 1982-1989.

We also adjusted standard earned premium from the NCCI expense review to a projected January 1, 1992 level based on historical rate activity and assuming the average rate change for 1991 is equal to the increase in the Index. We display both the direct and net ratios even though we recommend that NCCI utilize the direct ratios. We recognize that this trend procedure allows a general expense trend equal to the Index trend plus the trend in premium due to payroll increases of policyholders. The following table displays the adjusted expense indications.

Model 1: General Expense Indication for Stock Companies
As a Percentage of Standard Earned Premiums
(\$140 Expense Constant)
Adjusted To A January 1, 1992 Level

	Calendar Year						
	<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>	<u>Selected</u>
Net Ratios:	6.40%	5.91%	5.92%	6.08%	6.07%	6.28%	6.11%
Direct Ratios:			5.52%	5.69%	5.80%	5.93%	5.74%

As we are adjusting expenses and premium to a prospective cost and rate level, we would not expect the adjusted expense indications by year to display a trend. The adjusted direct general expense indications display an upward trend; therefore, the expense trend may not incorporate all of the factors that affect general expenses. If an exponential trend was applied to the direct ratios shown above for calendar years 1986 - 1989, the projected direct expense ratio as of January 1, 1992 is 6.3%. The selected values shown above are an average of the adjusted calendar year ratios.

The following table compares the rate change trend in NCCI states versus the Index trend.

EXPENSES

COMPARISON OF EXPENSE INDEX CHANGES TO RATE CHANGES

(1)	(2)	(3)	(4)
<u>Calendar Years</u>	<u>Expense Index Relative to 1982</u>	<u>Rate Changes Relative to 1982</u>	<u>Ratio of General Expense Factor to Rate Change Factor</u>
1982	100.0	100.0	1.00
1983	103.8	101.7	1.02
1984	107.7	102.1	1.05
1985	111.8	114.6	.98
1986	116.0	124.8	.93
1987	120.4	136.7	.88
1988	125.0	148.9	.84
1989	129.7	158.0	.82

One reason for the negative trend in general expense ratios is that rate changes are higher than the inflationary factors affecting general expenses. Rates increased 58% since 1982 (in addition to payroll growth). The Index increased only 29.7%. The differential growth rate over the seven year period is -18% (.82 - 1.0).

An alternate test (hindsight test) of the Model 1 trend approach is shown in Appendix B. In that appendix, we apply the procedure to data through 1987 to predict 1989 actual stock insurer expenses as reported in the IEE and data through 1986 to predict the 1988 expenses. We used the net experience for the hindsight analysis as NCCI has relied on net experience to derive a general expense provision. It is not appropriate to compare the NCCI net provision to the direct experience. In addition, the direct experience is not readily available for calendar years 1984 and 1985. Using data through 1987, the results of the trend method for stock company data are 0.26% (of standard premium) short of the actual expenses incurred while the results of the NCCI approach is 0.02% higher than actual. Using the data through 1986, the results of the trend method are 0.03% lower and the results of the NCCI review were 1.07% higher than the actual expenses incurred. The NCCI selection was closer using the 1987 data in part because NCCI at that time made an unusually sharp reduction in the general expense provision from the prior provision. In October 1988, NCCI

EXPENSES

decreased the general expense provision from 7.5% down to 6.7%, partly in response to an increase in the expense constant from \$120 to \$140.

If the inflationary factors that affect general expenses exceeded the historical rate changes then a trended expense indication would exceed untrended indications.

The second model (Model 2) is identical to the first model except that general expenses are not adjusted using the Index and a trend procedure is used to measure the net trend resulting from expense trends and payroll changes. For example, consider the following assumptions:

1. We know that General Expense dollars = 0.05% of nominal payroll;
2. General Expense dollars will increase by 5% per year;
3. Nominal payroll increases by 5% per year and there is no wage limitation;
4. Rates increase by 10% per year; and
5. Initial rate = \$1.00 per \$100 of payroll.

Based on the above assumptions, we can construct 4 sample years of experience and determine how the year 1 experience can be adjusted to estimate the year 4 expense ratio.

	<u>Year 1</u>	<u>Year 2</u>	<u>Year 3</u>	<u>Year 4</u>
Payroll in Year 1 dollars	10,000	10,000	10,000	10,000
Nominal Payroll	10,000	10,500	11,025	11,576
Rates	1.0	1.10	1.21	1.331
Premium	100.0	115.5	133.4	154.1
General Expenses	5.0	5.25	5.5	5.8
General Expense Ratio	5.0%	4.5%	4.1%	3.8%

In order to estimate the Year 4 general expense ratio using calendar year 1 experience, we would adjust premium to a current rate level $100 \times 1.331 = 133.1$

EXPENSES

and divide the actual general expenses in Year 1 by the premium at current rate level for Year 1 $(5/133.1) = 3.8\%$. The above analysis is performed on net (all size of risk data) and an additional adjustment can be made for the premium discount plan by adding the average discount for general expenses to the 3.8%. Thus, a first \$5,000 general expense provision can be computed.

The following table displays the adjusted expense indications from Model 2 on both a direct and net basis for stock companies. We adjusted standard earned premium from the NCCI expense review to a projected January 1, 1992 level based on historical rate activity and assuming the average rate change for 1991 is equal to the increase in the Index.

Model 2: General Expense Indications for Stock Companies
As a Percentage of Standard Earned Premium
(\$140 Expense Constant)
Adjusted to a January 1, 1992 Level

	<u>Calendar Year</u>						
	<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>	<u>Selected</u>
Net Ratios	5.54%	5.30%	5.40%	5.64%	5.72%	6.06%	6.51%
Direct Ratios			5.06%	5.30%	5.48%	5.73%	6.34%

The adjusted general expense indications display an upward trend for the 1985-1989 time period indicating that general expenses relative to premium are increasing by more than the trend in payrolls. The selected ratios are based on an exponential trend projected to January 1, 1992. Exhibits 14 and 15 display the net and direct calculations.

We also performed a hindsight test for Model 2 (Appendix B) using data through 1987, the Model 2 projected expense provision is lower than actual expenses by 0.60% while the results of the NCCI approach is 0.02% higher than actual. Using the data through 1986, the results of the Model 2 projections are lower than actual expenses by 0.44% and the results of the NCCI review were 1.07% higher.

EXPENSES

The third model is based on the method used by the Workers Compensation Rating and Inspection Bureau of Massachusetts (WCRB). The WCRB analyzes the most recent three calendar years of Massachusetts specific expense experience. A general expense ratio is applied to the Massachusetts standard earned premium for each of the three years. The estimated general expenses are trended (for inflationary factors) and adjusted for the growth in man-weeks to be consistent with the proposed policy period. The three years of estimated general expenses are then averaged to obtain an estimate of Massachusetts general expenses for the proposed policy period. The average general expenses are compared to the middle year (of the three years analyzed) standard earned premium adjusted to a current rate level and (using a payroll trend adjustment factor) to the mid-point of the period when the new rate level will be in effect. This ratio is then divided by one plus the indicated rate change. This procedure treats general expenses as a fixed expense component. Exhibits 16-19 display the Model 3 calculations. This procedure results in the following indicated expense provisions:

Model 3: General Expense Provision

Net	5.81%
Direct	5.57%

The hindsight test (Appendix B) produced an indicated expense provision of 6.22% for calendar year 1989 compared to an actual expense provision of 6.68%. Using data through 1986, the Model 3 expense loading is 6.49% for 1988 compared to the actual loading of 6.43%.

The following table summarizes the results of the three projection methods.

EXPENSES

General Expense Indications
As a Percentage of Standard Earned Premium
Adjusted to a January 1, 1992 Level

	<u>Calendar Year</u>						
	<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>	<u>Selected</u>
Model 1 (Expense Index Approach)							
Net	6.40%	5.91%	5.92%	6.08%	6.07%	6.28%	6.11%
Direct			5.52%	5.69%	5.80%	5.93%	5.74%
Model 2 (Trend Approach)							
Net	5.54%	5.30%	5.40%	5.64%	5.72%	6.06%	6.51%
Direct			5.06%	5.30%	5.48%	5.73%	6.34%
Model 3 (Massachusetts Approach)							
Net							5.81%
Direct							5.57%

For Model 1, the selected direct general expense loading as of January 1, 1992 is 5.74% which is an average of the 1986-1989 period. For Model 2, the selected general expense loading as of January 1, 1992 is 6.34% which is based on an exponential trend. The Model 3 indicated general expense loading is 5.6%

NCCI should utilize a procedure or procedures which reflects underlying trends in premium and expenses in selecting a general expense provision. Model 1 and Model 3 appear to project the more accurate "hindsight" results.

As we mentioned previously, a methodology which adjusts premium and expenses to a current rate and cost level will produce larger expense indications than the current NCCI methodology if the expense trend exceeds the level of rate changes. An example would be the early 1980's when the underlying expense costs (largely wages)

EXPENSES

were increasing at double digit rates while NCCI rate levels were flat or decreasing. As the attached Exhibit 20 displays, the ratio of general expenses to net earned premium for stock companies steadily increased from 5.5% in calendar year 1977 to 8.0% in calendar year 1983. Since 1983, the ratio has steadily decreased from 8.0% in 1983 to 4.9% in calendar year 1989.

As Exhibit 20 displays, the general expense ratios have exhibited substantial variability and NCCI should utilize procedures which attempts to explicitly reflect the underlying trends in premium and expenses. However, NCCI should not be confined to a specific methodology to establish expense levels as judgment is required with respect to:

1. Future rate changes:
 2. Future expense trends; and
 3. Underlying trends not measured by rate changes and expense trends.
2. Mutual Company Expense Experience

NCCI excludes mutual insurer expense experience from the general expense analysis. The NCCI rationale is twofold. First, the general expense review is intended to produce an expense indication for the first \$5,000 of premium and mutual companies in general write larger policy sizes. Second, the mutual companies have historically paid larger policyholder dividends than stock companies and part of the dividend reflects expense reductions.

However, mutual company expense experience can be adjusted to a first \$5,000 of premium using the mutual company policy size distribution and the same procedures NCCI uses to adjust stock expense data.

Furthermore, there is no significant difference between stock and mutual company general expense experience. Exhibit 21 displays the general expense indications (Page 1-Net, Page 2-Direct) adjusted to a first \$5,000 of premium level for both stock and mutual companies separately and combined utilizing our Model 1 procedure. The mutual company experience is adjusted to a stock basis for the first \$5,000 of

EXPENSES

premium based on the mutual premium distribution by size of policy and the stock expense gradations. This assumes that the average countrywide NCCI rate change is the same for stock and mutual companies.

We recommend that NCCI review the combined experience of mutual and stock companies to more accurately determine a rate for an average insured for the first \$5,000 of premium. Based on the combined experience, the direct expense indication projected to the period when rates will be in effect is 5.69% compared to the stock only indication of 5.74%.

The North Carolina Rate Bureau combines all companies experience (i.e., stock, mutual, reciprocal's and miscellaneous) in establishing general expense levels. NCCI staff reviewed mutual expense experience as part of the October, 1990 expense review and asked the Committee to decide if stock and mutual general expense experience should be combined in determining general expense levels. However, the Committee decided to continue to exclude mutual insurer experience from the calculation.

B. Production Expenses

Part of the expense constant provides for production expenses, (i.e., other acquisition expenses). The annual expense constant review was discussed previously. The variable provision for production expenses is established on a budgeted basis. NCCI incorporates a variable element of 15% for production expenses into manual rates for the first \$5,000 of standard premium. The premium discount plan reflects reduced production expenses for larger policies.

NCCI does not collect data useful to the analysis of the NCCI production expense provision of 15% for the first \$5,000 of standard premium. We recommend that NCCI review production expenses annually, as it does for other expenses, in establishing production expense provisions.

The expense study by size of risk should incorporate all production expenses (i.e., commission, brokerage and other acquisition expenses). Previously, it was limited to a review of other acquisition expenses only (Section VII).

EXPENSES

Based on our analysis, the budgeted first \$5,000 production allowance of 15.0% exceeds the actual amount projected to be expended by stock insurers, for combined voluntary and involuntary risks. The amount projected to be expended by stock insurers varied around 14.0% for calendar years 1985 through 1988 and is estimated at 13.0% for 1989. (Section VII, Page 63). Section VII discusses the use of the budgetary allowance in more detail.

C. Tax Provisions

With regard to premium tax provisions, the proper methodology to incorporate premium tax in the final rate will depend upon the interpretation of the NCCI final rate. If the NCCI rate is intended to be the average rate for the average company, then the tax provision should be based on the average taxes collected. If the NCCI rate is a benchmark for a specified type of insurer then the premium tax provision in the rate should be the tax rate appropriate for that type of insurer.

The current premium tax provision in manual rates (i.e., foreign insurer tax rate) will exceed the collected taxes relative to premium if:

1. The foreign tax rate exceeds the tax rate for domestic insurers;
2. Retaliatory taxes are not significant; and
3. Domestic insurers write a significant volume of business in the state.

The collected taxes in the state relative to premium will exceed the tax provision in manual rates if:

1. The domestic tax rate is similar to the foreign tax rate;
2. Retaliatory taxes are significant; and
3. Domestic insurers do not write a significant volume of business in the state.

EXPENSES

We agree with the NCCI treatment of the other tax provisions (excluding premium tax). However, we recommend that the detailed study of miscellaneous taxes be updated more often than was true in the recent past, once every ten years. NCCI is currently in the process of updating the 1981 detailed study of miscellaneous taxes.

D. Loss Adjustment Expenses

The NCCI Actuarial Committee selected a LAE provision of 12.0% based on the October, 1990 expense review.

The Committee reviewed, in the October 1990 expense review, the relationship between direct loss adjustment expense (LAE) and direct incurred (ultimate) losses as reported in the IEE for the most recent 3 and 6 year periods for both stock and mutual companies in order to establish a LAE provision. The Committee also reviews the net (i.e., of reinsurance) ratios. The following table displays the net and direct ratios for the most recent 3 calendar years.

	<u>Ratio of LAE to Losses</u>			
	<u>1987</u>	<u>1988</u>	<u>1989</u>	<u>Average</u>
Direct	12.09%	11.69%	11.71%	11.83%
Net	13.43	13.33	14.09	13.62

Section III outlined the reasons for differences between the net and direct ratios. While it appears that NCCI selected a provision based on the direct experience, NCCI does not explicitly state that direct experience is more appropriate.

We recommend that NCCI rely on direct losses and LAE for establishing a provision for LAE in ratemaking. In some state rate filings, NCCI displays only the net calendar year LAE indications. We recommend that NCCI also display the direct indications in rate filings.

Exhibit 22 displays the ratio of direct LAE to direct loss by accident year utilizing the carrier's estimates of direct ultimate LAE and direct ultimate loss from the NCCI

EXPENSES

accident year data call along with the NCCI's projected ultimate LAE ratio. NCCI projects the ultimate LAE to loss ratio based on the direct paid LAE to paid loss ratio from the special call and the net paid LAE to paid loss development factors from Schedule P aggregate experience for workers compensation.

NCCI first used accident year experience to review LAE in the October, 1989 expense review. When the Committee reviewed the special call accident year experience in February of 1991, it decided to revise the LAE provision to 12.5% largely based on NCCI's projected ultimate LAE ratio. The NCCI's projected ratio, for the most recent five accident years, varied from 12.3% to 13.2% (Exhibit 22).

On one hand, it appears that the ratio of direct LAE to direct loss by accident year is increasing. Based on the year-end 1989 evaluation, the ratio has steadily increased from 11.2% for accident year 1984 to 12.9% for accident year 1989 (based on the company's estimates, Exhibit 22). On the other hand, except for the least mature accident year, 1989, none of the accident years shows LAE in excess of 12.0%. Furthermore, when 1989 experience is excluded and accident years 1980-1988 are analyzed, regression projections through 1991 do not exceed 12.1%.

In addition, we observe that on average, NCCI's estimated ratio of LAE to losses exceeds the company's estimate for accident years 1980 through 1988 by 0.5 points, (Exhibit 22).

We also note that there are possible distortions due to the allocation of the ULAE to accident year. Company to company procedures may vary and within a company, procedures could vary by year. Furthermore, the Schedule P procedure used to assign ULAE by accident year may not be appropriate for ratemaking purposes.

In general, ULAE payments made during the current calendar year are allocated as follows on Schedule P:

1. 45% of the total ULAE payment is allocated to the most recent accident year;
2. 5% of the total ULAE payment is allocated to the next most recent accident year; and

EXPENSES

3. The remaining ULAE payments are distributed to all accident years including the most recent in proportion to the amount of loss payments for each accident year for the current calendar year.

A partial list of the factors effecting actual ULAE expenditures by accident year follow:

1. The complexity of claims (e.g., asbestos claims attributable to older accident years may require more ULAE costs) by accident year;
2. The mix of outside adjusters versus company personnel by accident year; and
3. Any company change in the definition of ALAE versus ULAE costs by calendar year.

We recommend that NCCI continue to review the special call experience and establish the LAE provision based on the special call experience. Based on the NCCI's analysis and the carriers estimates, a LAE provision between 12.0% and 12.5% of losses is indicated.

In the longer term, we recommend that ALAE be collected by claim and utilized similarly to losses in the ratemaking process (this is discussed in detail in Section V). A separate ULAE provision would then replace the current LAE provision, and the expense trend issue may become moot. If ALAE is collected by claim, NCCI will need to develop a procedure to reflect ULAE in the ratemaking formula. One possibility is to develop a countrywide ratio of ULAE to loss plus ALAE by analyzing the special call experience by accident year.

EXPENSES

E. Actual vs. Recommended Expense Provisions

NCCI expense provisions have overstated the actual amount of expenses incurred by the companies. This observation is seen in both general and production expenses.

A summary of our results can be seen on exhibits C-1 through C-3 in the technical appendix section, for calendar years 1986-89. The results of our analysis show that the expense provisions included in NCCI rate filings have exceeded the amounts actually incurred by the companies. A detailed discussion of our methodology used in arriving at this conclusion can be found in Technical Appendix C.

F. Conclusions and Recommendations

Our recommendations regarding possible improvements in the NCCI methodology are as follows:

1. Apparent underlying trends in the expense data should be reflected to the extent appropriate.
2. The general expense and loss adjustment expense provisions should be calculated in a manner that reflects the trends in the ratios. In addition, NCCI should establish expense provisions based on direct experience to the extent available. At this time, this might increase the LAE ratio and would decrease the general expense ratio.
3. The budgeted first \$5,000 production allowance of 15.0% exceeds the actual amount projected to be expended by stock insurers, for combined voluntary and involuntary risks. The amount projected to be expended by stock insurers varied around 14.0% for calendar years 1985 through 1988 and is estimated at 13.0% for 1989. Most, if not all of this difference, may be attributable to the lower commissions incurred on involuntary risks. This analysis assumes that the NCCI production expense gradations are appropriate. Production expenses are discussed in more detail in Section VII.

EXPENSES

4. The all size of risk analysis, indicates that the production allowance in the rates has exceeded the actual amount expended by stock insurers by 2.0 to 3.0 points of standard premium for calendar years 1986 to 1989. Based on our analysis, it appears that 1.5 to 2.0 points of this difference may be explained by the lower commission levels on involuntary business. The remaining difference is due to: (1) the expense gradations and (2) the fact that some stock carriers use the non-stock premium discount table. Production expenses are discussed in more detail in Section VII.
5. The NCCI production expense gradations are not based on data but were selected judgmentally. Therefore, we recommend that NCCI collect all production expenses by size of risk in order to determine the appropriateness of the production gradations. Production expenses are discussed in more detail in Section VII.
6. With regard to premium tax provisions, the proper methodology to incorporate premium tax in the final rate will depend upon the interpretation of the NCCI final rate. If the NCCI rate is intended to be the average rate for the average company, then the tax provision should be based on the average taxes collected. If the NCCI rate is a benchmark for a specified type of insurer then the premium tax provision in the rate should be the tax rate appropriate for that type of insurer.
7. We agree with the NCCI treatment of the other tax provisions (excluding premium tax). However, we recommend that the detailed study of miscellaneous taxes be updated more often than was true in the recent past, once every ten years. NCCI is currently in the process of updating the 1981 detailed study of miscellaneous taxes.
8. General expense calculations should be based on combined stock and mutual insurer expense experience. This is not expected to have a material impact on the selected expense provision.
9. NCCI should further investigate the differences between the calendar year LAE ratios and the accident year LAE ratios, including a review of ULAE reserves by accident year.
10. NCCI should rely on direct losses and LAE expenses for establishing a provision for LAE in ratemaking and should display the direct indications in rate filings.

EXPENSES

11. NCCI should further investigate the difference between the various LAE to loss indications by accident year (carrier's estimate versus NCCI projection method).
12. The NCCI general and production expense ratios are based on (1) premium at NCCI rate levels, in states where NCCI files gross rates, or (2) premium at NCCI loss cost levels and standard NCCI profit and expense levels in states where NCCI files loss costs. With respect to general expenses, NCCI attempt to use a common base for expense analysis purposes is reasonable. However, as more states become loss cost states, NCCI should review the appropriateness of combining loss cost states with states where NCCI publishes rates.

EXPENSES

V. OBJECTIVE 2b: COSTS AND BENEFITS OF COLLECTING ALAE BY CLAIM

This section addresses the following objective of the RFP:

Objective (2b) Expenses - What would be the incremental cost of collecting allocated loss adjustment expenses (ALAE) on a unit basis? Discuss the pros and cons of having this level of statistical detail available versus what is now available. Also, discuss whether it would be more cost efficient to collect this data only as needed, e.g., retrospectively rated risks and residual market risks.

A. Issues Involved in Collecting ALAE by Claim

To collect ALAE by claim, the unit statistical reports and financial call formats need to be modified to include ALAE information. Companies will need to change procedures to collect and report ALAE. NCCI conducted an Impact Analysis to determine the obstacles companies face in collecting ALAE by claim. In addition, we worked with NCCI to develop a Cost/Benefit Analysis Survey and NCCI issued the Survey to 30 companies to determine the costs the companies will incur if incurred ALAE is collected by claim. There were 21 company responses to the Cost Benefit Analysis Survey.

To collect accurate data, NCCI and its members need a definition which distinguishes ALAE from ULAE and losses. The proposed NCCI definition is attached as Exhibit 23. Under this definition ALAE includes the following: attorneys' fees and fees of other authorized representatives when these legal fees can be directly allocated to particular claims, court costs, the costs of alternative dispute resolution procedures, medical cost containment expenses and vocational rehabilitation evaluation costs.

Exhibit 24 displays how 17 companies responded to one or more of the Impact Analysis questions on the manner in which they classify expenses which the NCCI proposal considers ALAE (not all 17 companies responded to every question.) Several items in the proposed NCCI definition of ALAE are currently treated as either ULAE or losses by individual companies. For example, for hospital utilization review expenses (Item 3(b)), 8 of the 17 companies surveyed classified the expense as ALAE,

EXPENSES

whereas 4 companies classified the expense as ULAE, and 5 companies classified the expense as a loss amount. Thus, training of company personnel will be necessary in order to properly classify the proposed items as ALAE.

The Survey asked companies to estimate the cost of collecting incurred ALAE (paid plus case reserve) by claim and reporting ALAE in the same detail as losses to NCCI.

Based on the companies responding to the Survey, the majority of companies reserve for ALAE on a bulk basis and not by individual claim. Based on the comments from the NCCI Impact Analysis, companies stated that establishing reserves by claim will be difficult. Claim systems will require modifications and claim adjusters will need additional training. Of the 21 companies that responded to the Survey only 7 currently establish case reserves for ALAE.

Significant time lags will exist with respect to collecting ALAE by claim. The majority of carriers responding to the Impact Analysis stated that it would take one or more years to identify and capture expenses under the new definition. In addition companies stated that "major" computer system enhancements would be necessary to report the data.

The following table displays the average absolute dollar cost (of collecting and reporting ALAE by claim) and the cost as a percentage of the company's workers compensation premium by size of company.

<u>Company Size</u>	<u>Number of Companies</u>	<u>Average Dollar Cost</u>	<u>Cost as a Percentage of W.C. Premium</u>
Small	5	\$ 28,320	0.49%
Medium	11	103,145	0.11
<u>Large</u>	<u>5</u>	<u>334,496</u>	<u>0.03</u>
Total	21	\$140,413	0.05%

Exhibit 25 displays the dollar cost and cost as a percentage of premium for each of the 21 companies responding to the Survey. The percentage cost is well under 1.0% of workers compensation premium for all but two of the insurers.

EXPENSES

The following table displays the average absolute dollar cost (of collecting and reporting ALAE by claim) and the cost as a percentage of the company's workers compensation premium for companies that currently establish ALAE reserves by claim, and for companies that do not establish ALAE reserves by claim.

<u>Group</u>	<u>Number of Companies</u>	<u>Average Dollar Cost</u>	<u>Cost as a Percentage of W.C. Premium</u>
Companies that do not establish ALAE reserves by claim	14	\$180,514	0.09%
Companies that currently establish ALAE reserves by claim	<u>7</u>	<u>60,211</u>	<u>0.01</u>
All Companies	21	\$140,413	0.05%

As a separate cost component, NCCI estimated that it will cost \$1.4 million in order for NCCI to collect ALAE as a separate item. The cost can be broken down into the following two elements:

NCCI Cost To Collect and Use ALAE
(\$ Millions)

Technical Service Costs	\$1.1
User Department Costs	<u>.3</u>
Total	\$1.4

In addition, if ALAE was collected by claim for only residual market and servicing carrier business the overall costs would not be reduced significantly based on the responses to the survey. Therefore, it is cost effective to collect ALAE by claim for all business.

EXPENSES

B. Rate Accuracy - Trends in ALAE

NCCI requested companies to provide paid and outstanding losses, ALAE and ULAE on a direct basis by accident year. However, carriers do not now define ALAE in a uniform manner; the ALAE in this exhibit (Exhibit 26) is based on each company's own definition. Each company's definition is believed to be consistent over time. The projected ultimate ALAE in Exhibit 26 is based on each company's reserves; no adjustment to IBNR is made by NCCI.

The ratio of ALAE to loss in this Exhibit has increased from 4.5% in accident year 1980 to 5.8% for accident year 1989. The data imply that ALAE as a percentage of losses is increasing by 3.1% per year and implies ALAE for accident year 1991 will equal 6.2 percent of losses. Section IV discussed an upward trend indicated in analyzing total LAE and this appears to be traceable to the trend in ALAE.

If ALAE were collected and analyzed with statewide ratemaking data, trends in ALAE would be more properly included in the overall rate level process than at present.

C. Rate Equity

Treating ALAE like losses in the ratemaking process will result in more accurate rates by state, industry group, and classification. For example, the propensity to incur legal costs varies by state.

If ALAE is included with losses, the ratemaking methodology would reflect the relative susceptibility of various classes to ALAE costs. For example, assume Class A generates LAE costs of 15.0% of losses and Class B generates LAE costs equal to 9.0% of losses. Then, utilizing the current NCCI methodology both classes' rates include a LAE provision of 12.0% of losses. Therefore Class B is subsidizing Class A; a more equitable approach is to base class rates on experience including ALAE.

These issues are more significant as the ratio of ALAE to losses has been increasing. The ratemaking methodology for most casualty lines of insurance combines loss and ALAE. Personal injury protection, the first party coverage for wage loss and medical

EXPENSES

expenses for automobile accidents in no fault states, is probably the coverage most similar to workers compensation. Generally loss and ALAE are combined in the ratemaking methodology for personal injury protection.

D. Retrospectively Rated and Residual Market Policies

For retrospectively rated policies, if the insurance company pays a claim, the insurer can often collect additional retrospective rating premium. However, the insurer defending a claim will not receive additional retrospective rating premium for the ALAE incurred if the claim settles for \$0. This is due to the fact that LAE charges in the retrospective rating formula are included as a factor on losses; actual expended LAE is not reflected. This fact can create the perception that insurers inadequately defend claims under retrospectively rated policies. A similar situation can exist for servicing carriers for assigned risk business. If the insurer pays a claim, the insurer can get reimbursed by the residual market pool. However, currently ALAE expenditures are not directly reimbursed. A provision for total LAE is included in the servicing carrier allowance. By collecting ALAE information in detail, retrospectively rated policies and residual market mechanisms can be designed to directly reimburse carriers for ALAE as well as for loss.

The following factors favor the use of directly reimbursable ALAE costs:

1. Eliminate the perception of an insurer inadequately defending claims.
2. Reduce or eliminate potential for cross-subsidization in that loss and ALAE are tracked to the policyholder involved.
3. May encourage improved claim handling.
4. Increase visibility of the costs of investigating and settling claims.

Thus, both insurers, policyholders and regulators may prefer a system of directly reimbursable ALAE.

EXPENSES

On the other hand, we have the following observations:

1. In practice, it is not practical for a company claim department to have one process for handling residual market and retrospective policy business and a separate method for voluntary, guaranteed cost business.
2. Company claim practices are monitored by audits.
3. Reinsurance agreements regularly require companies to defend claims even when successful defense reduces the reinsurance recoverable.
4. A system which directly reimburses ALAE may not give insurers a sufficient incentive to control ALAE costs.

E. Conclusions and Recommendations

1. The benefits of collecting ALAE information by claim include the following:
 - Increased accuracy in ratemaking.
 - Increased equity in ratemaking.
 - Addressing concerns about the adequacy of insurer defense efforts in situations such as retrospectively rated policies and residual market servicing carrier business where insurers have reduced claim risk but bear the full cost of claim defense.
2. The disadvantage of collecting ALAE information by claim is the additional cost of those efforts, but the overall cost (0.05% of premium) is relatively low. NCCI may want to consider a transition program for companies incurring a relatively higher cost.
3. Generally, loss cost states permit the rating organization to include ALAE as part of loss costs. However, if some states do not permit NCCI to include ALAE in loss costs then the NCCI procedure for collecting and utilizing the data needs to be sufficiently flexible to exclude the information when required.

EXPENSES

4. The NCCI Actuarial Committee recommended that ALAE be collected by claim and recommended a January 1, 1993 effective date for collecting ALAE by claim. We agree with the Committee recommendation that ALAE be collected by claim. The NCCI Board will vote on the collection of ALAE next year.

EXPENSES

EXPENSES

VI. OBJECTIVE 2c: STATE SPECIFIC EXPENSE ISSUES

The RFP contained the following objectives.

Objective (2c) Expenses - Should large state rate increases be tempered because of less than proportional increases in expenses?

When a state's premium and rates grow faster than the national average, the question arises of whether expenses are increasing in proportion to the increase in premiums. If not, the question arises of whether larger than average increases should be tempered.

For reasons mentioned later in this section, we do not recommend that standard NCCI procedures include tempering expenses when state rate changes are large. We believe that the tempering issue is more correctly viewed as the issue of whether expenses ratios should vary by state. Sub-section D discusses varying expense ratios by state.

Exhibits 27-31 display the annual rate changes for NCCI states (i.e., states where NCCI publishes rates or loss costs) in various rate change intervals for the 1986-1990 time period. The larger the rate increase/decrease, the greater the effect on expenses. As Exhibit 27 displays for 1990, 5 of the 38 states had a rate change in excess of 17.5%. While the issue may not arise frequently, it is important in those states where it does arise.

For the purpose of this section, we assume that the countrywide expense provisions are appropriate for all states combined.

A. Impact of Rate Increases on Expenses

A rate change due to loss experience or benefit changes alters the amount of premium collected for expenses. As discussed in Section III, the following variable loadings are incorporated into current manual rates.

EXPENSES

<u>Variable Expense</u>	<u>Provision In Manual Rates</u>
General Expenses	6.7%
Production Expenses	15.0
Taxes - Varies by State	4.2*

* average

The expense dollars produced by these provisions increase in proportion to the premium increase. In addition, loss adjustment expenses (LAE) are included in manual rates as 12% of expected losses.

On the other hand, the expense constant of \$140 (depending on state) does not change as a result of a rate increase. The expense constant provides 20% of general expense and 6% of production expense revenue. The premium discount plan will moderate the expense increase resulting from a rate change if an insured's premium is shifted into a higher standard premium division.

The following table displays the combined general, production and tax provisions in a risk's premium before and after a 20% rate change for risks of various premium sizes.

Effect on Expenses with a 20% Rate Increase

<u>Premium Size Before Rate Change</u>	<u>Expenses Before Rate Change</u>	<u>Expenses After Rate Change</u>	<u>Percentage Expense Increase</u>
\$ 4,000	\$ 1,178	\$ 1,385	17.62%
25,000	4,605	5,397	17.20
150,000	23,555	27,797	18.01
750,000	104,395	123,205	18.02

✓

EXPENSES

As expected, the expense increase is less than the premium increase due to the expense constant. Exhibits 32 (Pages 1 through 4) displays the combined general, production and tax provisions before and after various rate changes for various risk sizes. LAE and profit and contingencies were not included in the analysis.

B. Techniques for Tempering - Expense Flattening

As an alternative to the current procedure which treats all expense elements as variable in the development of manual rates, the components could be split between fixed and variable elements (the expense constant is a fixed element, but it is considered separately from the overall rate change in the ratemaking process). The procedure of splitting fixed and variable expenses is utilized for classification ratemaking as well as overall ratemaking for other lines of business.

If the rate change in an individual state was large, the general expense provision might be treated as a fixed element which does not increase with premium.

Expenses other than general expenses are more likely to vary in direct relationship to a rate change. Agent's commissions which represent the majority of the production expense component is typically a flat percentage of premium for smaller risks and is graded by premium size for larger risks. Therefore it will increase as rates increase. In a similar manner, LAE costs are a function of losses, and if losses increase LAE costs will generally increase.

Following is an example of the indicated rate change (based upon experience) under the NCCI current ratemaking methodology and a methodology which flattens expenses based on the NCCI January 22, 1990 filing in Missouri with an effective date of April 1, 1990. From Exhibit II of the Missouri filing, we find the following provisions:

Production Cost	15.0%
General Expense	7.5
Taxes, License and Fees	2.8
Profit and Contingencies	<u>2.5</u>
Total Overhead Provisions	27.8

EXPENSES

Given the Missouri provisions, 72.2% (100% - 27.8%) is considered the permissible loss ratio by NCCI. Based on the NCCI analysis, the projected loss ratio for the experience period is 84.55%. The rate change based on experience is:

$$\frac{\text{Projected Loss Ratio}}{100\% - \text{Total Overhead Provisions}} - 100\% = \frac{84.55}{72.20} - 100\% \text{ or } 17.1\%$$

If a flattening of expense methodology was introduced, the rate change formula is modified as follows:

$$\text{Rate Change} = \frac{\text{Projected Loss Ratio} + \text{Fixed Expense Component}}{100\% - \text{Variable Expense Components}} - 100\%$$

If we assume that all general expenses are fixed expenses while all other expenses are variable, then the fixed expense component is 7.5% and the variable expense component is 20.3% (production, taxes, and profit and contingencies). The indicated rate change under an expense flattening program is:

$$\frac{84.55\% + 7.5\%}{100\% - 20.3\%} - 100\% = \frac{92.05\%}{79.7\%} - 100\% \text{ or } 15.5\%$$

Thus the rate indication is reduced from 17.1% to 15.5% if we assume that general expenses are a fixed component.

Exhibit 33 displays indicated rate changes utilizing the NCCI recommended expense provisions based on the October, 1990 expense review under the NCCI ratemaking methodology and a methodology that flattens expenses. The effect of expense flattening is to reduce a rate change of 20% to a rate change of 18.3%.

EXPENSES

C. Analysis of "Tempering"

The technique described above makes a number of assumptions, including the following:

- The result of the process is an equitable distribution of countrywide general expenses by state.
- The general expense provision in the prior rates was adequate.
- General expense does not vary with premium.
- Production expenses (other than the expense constant) vary directly with premium.

There are a number of issues to be decided before determining whether tempering is proper as a standard procedure.

First, if the expense provision is established correctly on a countrywide basis (considering likely countrywide premium increases) then tempering expenses in one state without offsetting increases in other states leads to an overall expense deficiency.

Second, as mentioned previously, there has been a downward trend in general expenses which may be partly due to the level of rate increases implemented in the past. The selection of a lower countrywide general expense provision may address the tempering issue in a countrywide manner.

Third, there may be no reason to believe that expense levels were adequate prior to the rate increase. If a large increase is required because of continuing rate level inadequacies in the state, then the expense provision is likely to be as deficient as the loss provision. If the increase is due to a law change which results in a relatively high level of benefits, then expense tempering might be more appropriate.

EXPENSES

Fourth, there are several factors that mediate the expense impact of a large rate increase in a state including the fact that more than 40% of the countrywide premium is from multi-state risks and risks which are greatly impacted by premium discount tables. Exhibit 34 displays the premium distribution of intrastate and interstate risks by state. For example, for Alabama, 47.4% of the state's premium is attributable to intrastate risks (i.e., Alabama-only risks) and 52.6% of the premium is attributable to risks with operations in several states.

A more appropriate expense question is whether expenses should vary by state, i.e. are expense ratios lower in some states because of either higher than average loss costs or lower than average state operating costs. This issue is discussed in the next section.

D. Expenses by State

NCCI utilizes state specific expense provisions (if required) based on call #14 which collects direct expenses by state; otherwise, NCCI utilizes countrywide (IEE) expense indications. If a state requires NCCI to establish rates based on only the state's expense experience, the state expense experience is still included in the countrywide experience. The following section analyzes the reasonability of NCCI utilizing a countrywide expense factor versus varying the factor by state.

NCCI data call #14 collects the following direct experience by state:

1. Written Premium
2. Net Earned Premium
3. Standard Earned Premium
4. Commission and Brokerage Expenses
5. Other Acquisition Expenses

EXPENSES

6. Losses (both paid and outstanding)
7. ULAE (both paid and outstanding)
8. ALAE (both paid and outstanding)
9. Board and Bureau Expenses
10. Audit, Inspection and Other General Expenses
11. Taxes, Licenses and Fees

We analyzed state specific general and production expenses to determine if significant expense differences exist by state. We analyzed combined stock and mutual companies experience. The reciprocal exchanges, state funds, and miscellaneous companies were excluded. We believe it is appropriate to exclude these companies, as state funds for example, have different commission schedules and general expense requirements than stock and mutual companies. In addition, we restated the state expense levels to a first \$5,000 basis based on the NCCI expense gradations by size of risk and the state premium distribution by size of risk from the unit statistical report (Exhibit 34). Ideally, the size of risk distribution should include premium generated by the risk in all states in which the risk generates premium; however, this data is not available. This limitation will affect the magnitude of the ratios; however, we believe that the comparison of the relative expense ratios by state is still appropriate.

Exhibit 35 displays direct general expenses as a percentage of direct standard earned premium adjusted to a first \$5,000 basis for calendar years 1987, 1988, 1989 and the combined 1987-1989 time period. We arranged the states from lowest general expense ratio to highest, based on the calendar year 1987 ratios. For 1988 and 1989 and the combined 1987-1989 period, we then determined the respective general expense rankings. For example, Utah had the second lowest general expense ratio in 1987, the eighth lowest in 1988, the fifth lowest in 1989, and for the 1987-1989 period ranked second. The restated first \$5,000 general expense ratios are also displayed next to the rankings. Exhibit 36 is a similar exhibit that displays production expense ratios relative to direct standard written premium.

EXPENSES

We performed two statistical tests to determine if the rankings for a state were correlated across years. The tests measure whether low expense ratios in one year are more likely to be associated with low expense ratios in subsequent years or whether the expense ratios (rankings) vary significantly from year to year.

The two tests utilized are:

1. A chi-squared test based on the coefficient of concordance; and
2. A normal test based on Spearman's rank correlation coefficient.

These tests are described in Technical Appendix D.

Both tests rejected the null hypothesis of no correlation of expense rankings by state across years. Therefore, low rankings in one year are more likely to be associated with low rankings in subsequent years.

The correlations of rankings by state may be a function of several factors. The relative mix of the distribution systems by state may vary. In general, direct writers have lower production expenses than agency companies. Second, in determining the restated expense ratios to a first \$5,000 basis, we utilized the unit statistical reports. This may bias the analysis. Third, states with higher average rate levels would tend to have somewhat lower expense needs as a percentage of premium. Finally, individual company allocation procedures may distort the expense ratios.

In order to determine the distortion due to individual company allocation procedures, we analyzed the procedures that companies use to allocate general and production expenses to state. The state allocation procedures used by the individual companies is also discussed in Part I of the report, the Data Collection Phase. NCCI data call #14 contains the following 7 allocation codes that companies use to allocate expense items to state:

1. Actual Expenses
2. Written Premium

EXPENSES

3. Earned Premium
4. Losses
5. Salaries
6. Time Study
7. Other

Exhibit 37 displays the various allocation procedures that the twenty-five largest countrywide workers compensation companies utilized in allocating general and production expenses to state in NCCI data call #14. For example, for commission and brokerage expenses, 16 of the 24 companies (companies that used two allocation codes for the same expense item are excluded) capture the actual commission and brokerage expenses by state; 6 companies allocate their countrywide commission and brokerage expenses to state based on written premium; and 2 companies utilize some other procedure to allocate commission and brokerage expenses to state.

For general expenses, the majority of the companies use either written or earned premium to allocate countrywide general expenses to state. In order to further investigate the availability and accuracy of the general expense data by state, we worked with NCCI to develop a survey and NCCI issued the survey to 16 companies. The sampled companies included many of the large national writers of workers compensation insurance.

Exhibit 38 summarizes the results of the survey. For other general expenses, only 3 of the 16 companies surveyed allocate branch office--general expenses to the states that the branch offices serve. The other 13 companies combine all general expenses into a countrywide total and then allocate that total to state based on earned or written premium. In fact, only 3 of the companies surveyed stated that general expenses can be identified at the branch office level. Exhibit 39 displays the actual survey form.

On the one hand, it appears that expense levels vary significantly from state to state; however, on the other hand, we would expect that the expense ratios should not vary

EXPENSES

(in particular for general expenses) based on the allocation procedures that companies utilize to allocate expenses to state.

It is our recommendation, given the correlation of expense ratios by state, that additional research be performed. To the extent that verifiable differences exist by state, NCCI should reflect state expense levels in the ratemaking process.

E. Conclusions and Recommendations

1. We do not recommend that standard NCCI procedures include tempering expenses when state rate changes are large.

The rationale for this recommendation includes:

- a. If expenses are reflected correctly on a countrywide basis, adjustment for large rate increases may result in an inadequate countrywide expense provision.
- b. The downward trend in general expense, (as noted in Section IV), is due in part to the level of rate increases implemented in the past, and the countrywide expense provision should consider that trend.
- c. If rates are deficient over a period of time, it is likely that expenses are also deficient.
- d. There are factors to mediate the expense impact of a large rate increase in a state including the fact that more than 40% of the premium is from multi-state risks and risks which are greatly impacted by the premium discount tables.

2. The issue of tempering expense provisions is more correctly viewed as the issue of whether expense ratios should vary by state. NCCI data suggests that there are variations from state to state; however, allocation procedures distort the expense analysis by state. Additional research should be performed to determine the appropriateness of varying expense levels by state. To the extent that verifiable

✓
EXPENSES

differences exist by state, NCCI should reflect state expense levels in the ratemaking process.

EXPENSES

EXPENSES

VII. OBJECTIVE 2d: BUDGETED APPROACH TO ACQUISITION EXPENSES

This chapter discusses the following objective of the RFP:

Objective (2d) Expenses - Discuss the advantages and disadvantages of the budgeted approach to acquisition expenses versus basing these factors on actual expense experience.

A. Current Procedure for Selecting Stock Insurer Production Expense Provisions

NCCI defines production expenses to include:

1. Commission and brokerage incurred; and
2. Other acquisition, field supervision and collection expenses incurred.

These items are displayed on line 5 and 6 of Part II of the IEE for workers compensation.

In establishing production provisions it is reasonable to combine commission and brokerage expenses with other acquisition, field supervision, and collection expenses. Agency companies will typically incur larger commission and brokerage expenses than direct writers relative to premium; whereas, direct writers will incur larger other acquisition expenses. If the two provisions were not combined the separate allowances would vary by type of insurer. Independent agents typically perform functions that reduce an insurer's in-house acquisition costs and agents receive reimbursement for this service. The direct writing company agents are employees, and more of the production related expenses are allocated to other acquisition expenses; therefore direct writers incur lower commission related expenses.

NCCI judgmentally selects production expense allowances, and does not support these expense provisions with a specific analysis of expense data. This is described by NCCI as a "budgetary approach".

EXPENSES

NCCI states that a budgetary allowance is appropriate as companies negotiate unique commission schedules with agents and an average of the actual commissions produces an average which is not appropriate for any particular company.

The first \$5,000 of standard premium incorporates a 15% loading for production expenses and the percentage loading decreases as the premium size increases. The following table displays the production allowances for various premium sizes for companies electing the stock premium discount plan.

<u>Division of Premium</u>	<u>Stock Production Expense Allowance</u>
First \$ 5,000	15.00%
Next 95,000	7.50
Next 400,000	6.00
Over 500,000	6.00
Average based on 1987 - 1988 policy size distribution	8.55

These provisions along with the production expense component of the expense constant of \$47.35 are intended to provide an adequate provision for production expenses.

B. Actual Production Expenses Versus Budgeted Expenses

A disadvantage of the budgetary approach of establishing the production expense allowance is that the actual production expenses incurred are not used in determining the expense allowance in the rates. If actual expenses are less (more) than the budgetary allowance then the "average" company will sustain a gain (loss) that is more (less) than that anticipated by the regulator.

EXPENSES

1. Provision in Manual Rates - Stock Insurers

NCCI staff in their 1990 expense review examined the production expense experience for stock companies. The methodology of this review is similar to the general expense review. The NCCI analysis is attached as Exhibit 40. Row 1 of Exhibit 40 displays the net earned premium converted to a standard earned premium basis. The premium is converted to a standard basis to derive a provision for the first \$5,000 of standard premium. The standard premium is the premium before (excluding) any retrospective rating adjustments, premium discount (expense gradation), schedule rating and carrier deviations.

The schedule rating and carrier deviation adjustments represents approximately 2.7% of standard premium for calendar year 1989. After the aforementioned adjustments, Row 1 is an estimate of the manual premium (i.e. the premium based on manual rates) times the average experience modification plus the expense constant. These adjustments, are made to convert individual insurer rates to an NCCI rate level. The budgetary production allowance is intended to be a percentage of NCCI rates. If individual companies utilize downward (negative) deviations then the companies will collect less than the NCCI budgetary production allowance.

The expense constant offset, Row 2, is utilized to determine the amount of standard premium generated from the expense constant of \$140 in total. The expense constant offset is adjusted to a projected January 1, 1992 standard premium level. This adjustment is necessary as the insurers record the expense constant as premium. Row 3 is an estimate of the standard premium excluding the expense constant revenue and Row 1 minus Row 3 is an estimate of the expense constant revenue assuming the \$140 expense constant. As mentioned, \$140 expense constant was recommended by the Actuarial Committee based on the October, 1990 expense review.

Row 4 displays the stock insurer's production expenses from the IEE. Row 5 is the portion of the expense constant revenue that is associated with production expenses. Exhibit 41 displays the calculation of the expense constant revenue that is associated with production expenses. The calculation is based on the production and general expense constant elements from the 1982 study of expenses by size of risk.

EXPENSES

Row 6 is the IEE production expenses less the expense constant revenue associated with production expenses. Therefore, Row 6 represents the amount of production expenses which need to be priced for through the variable expense loading.

To determine the expense allowance which should be incorporated into manual rates (first \$5,000) the Row 6 amount is adjusted for the service carrier allowance and the average premium discount for production expenses.

Row 7 displays an adjustment required for the way servicing carriers record production expenses. This adjustment is discussed in detail in Technical Appendix A.

Row 8 displays the adjustment for the average discount for production expenses underlying the premium discount plan and is needed to convert the expense provision from an average provision to a provision for the first \$5,000 of standard premium. The average discount is projected to a January 1, 1992 distribution of risks by policy size. The detailed calculation is displayed on Exhibit 42.

We would modify the NCCI production review for stock companies by computing the production expense ratio as a percentage of written premium instead of earned premium. Relating production expenses to written premium results in a more accurate matching of expenses and revenue as commission expenses are expensed during the period in which the policy was written even though not all of the premium was earned.

In addition, we believe that direct experience is more appropriate than net (of reinsurance) experience as NCCI rates are intended to be sufficient for the primary carrier.

However, sufficient data is not available at this time to determine the direct indications and several assumptions are required for the direct analysis. Other acquisition, field supervision and collection expenses incurred (other acquisition) are not available from the IEE on a direct basis and the carriers methodology for recording the servicing carrier allowance may bias the net other acquisition expenses incurred. As displayed on Exhibit 40, the 1989 adjustment necessary to eliminate the effect of the servicing carrier allowance from the net production allowance indication is negative 1.7 points of standard premium. NCCI did not collect data sufficient to

EXPENSES

determine the required adjustment separately for commission and brokerage and other acquisition expenses. NCCI is in the process of collecting this information for the October, 1991 expense review.

Several adjustments are also required to convert direct written premium to a standard basis as several data items are not directly available from the IEE on a direct basis. Therefore, we have only adjusted the NCCI indications from a net earned to net written premium basis.

The following table displays the first \$5,000 production expense indications for stock companies based on the NCCI analysis (earned premium) and our modified analysis (written premium):

Production as % of	Stock Production Expenses Indications					
	Calendar Year					
	1984	1985	1986	1987	1988	1989
Earned Premium	15.2	14.4	13.9	14.2	14.1	13.0
Written Premium	15.3	14.3	13.8	13.9	13.9	13.0

The effect of using written premium as the denominator is relatively minor during the 1984-1989 time period. However, the effect is a function of the difference between written and earned premium and could be larger under several scenarios.

Both analyses clearly display a downward production expense trend and the budgeted 15.0% allowance exceeds the actual amount incurred in 1989 of 13.0% by 2.0 points. However, the trend may be partially explained by the growth in the residual market population. In general, the residual market producer fee schedules provide commission levels which vary by state but approximate 5.5% for the first \$5,000 of standard premium. The following table displays the growth in the residual market for the 1984-1990 time period:

EXPENSES

<u>Residual Market Premium Relative to Total Direct Premium</u>						
<u>Countrywide</u>						
<u>Calendar Year</u>						
<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>	<u>1990</u>
5.5%	9.7%	16.3%	19.0%	19.6%	22.0%	24.1%

Technical Appendix E discusses the residual market producer fees in more detail.

2. Provision in Manual Rates - Mutual Insurers

We performed a production analysis for mutual companies. NCCI did not perform an analysis of mutual companies' production expenses. We restated the mutual companies' production expenses to a first \$5,000 basis based on the stock expense gradations underlying the stock premium discount table and the mutuals distribution of risks by size of policy. The ratios are projected to a January 1, 1992 size of risk distribution. Exhibit 43 displays the production expense indication for the first \$5,000 of standard premium for both stock and mutual companies. The following table displays the indicated mutual production expenses by year for the first \$5,000 of standard premium.

<u>Production</u> <u>as % of</u> <u>Written</u> <u>Premium</u>	<u>Mutual Production Expenses Indications</u>					
	<u>Calendar Year</u>					
	<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>
	15.0	12.8	12.7	14.3	12.8	11.7

The 15% budgeted production allowance exceeds the 1989 actual net production expenses incurred of 11.7% by 3.3 points.

One major limitation of our analysis is that we have assumed that stock and non-stock production expense follows the NCCI premium discount plan. We cannot analyze the current or historical accuracy of this assumption because the 1982 study of expenses by size of risk did not capture commission and brokerage expenses, and there are no current sources containing this information.

EXPENSES

3. Net Provision - Stock Insurer

An alternative method of analyzing the appropriateness of the production expense provision for stock companies is to compare the actual IEE production expenses incurred to the average production allowance incorporated into the rating plan. Based on the stock production allowances by size of risk and the distribution of risks by premium size, we can estimate the average production allowance incorporated into the rating plan relative to standard premium. As mentioned previously in this section, the average stock production allowance anticipated in the NCCI rating plan for voluntary risks based on the 1987 - 1988 distribution of risks by premium size is 8.55%. To determine the actual production allowance for calendar year 1989 for stock companies we need to adjust for:

- a. the lower filed commission allowances in some states for residual market business;
- b. the premium written by stock companies utilizing the non-stock premium discount table;
- c. the shift in the distribution of policies by size of risk between 1987-1988 and 1989.

Based on these adjustments, the 1989 adjusted production allowance incorporated into the rating plan as a percentage of standard premium is 9.1%. Technical Appendix F displays the detailed calculation for the 1989 adjusted production allowance. The following table displays the actual net IEE production expense ratios relative to standard written premium for stock companies. This table includes stock insurers using the non-stock discount table and excludes non-stock insurers using the stock table.

EXPENSES

Stock IEE Production Percentages
As a Percentage of Standard Written Premium
Excluding Expense Constant Revenue (\$140 Expense Constant)

	<u>Calendar Year</u>					
	<u>1984</u>	<u>1985</u>	<u>1986</u>	<u>1987</u>	<u>1988</u>	<u>1989</u>
Stock %	8.3	7.4	6.8	6.9	6.9	6.0

The production expense allowance in the rating plan, 9.1% in 1989, exceeds the calendar year 1989 actual production expense allowance of 6.0% by 3.1 points of standard premium. Again, we believe that direct expense ratios should be analyzed, but sufficient experience is not available for that analysis.

Possible explanations for the decreasing production expense ratio displayed in the above table are:

1. The growth in the residual market in which producer compensation is lower than in the voluntary market. We previously discussed the growth in the residual market;
2. Negative underwriting results may have reduced the amount of contingent commission paid to agents; and
3. Insurers may have responded to negative underwriting results by offering lower commission rates to agents.

The relatively dramatic decline in commission rates during the last five years may reverse itself if underwriting results improve and the residual market is depopulated.

C. Conclusions and Recommendations

1. The total production expense provision for stock companies - for voluntary and involuntary risks combined - exceeds amounts actually incurred by 2% or more. It appears that the 15% provision in manual rates exceeds the amount incurred of
-

EXPENSES

13.0% by 2.0 points in 1989; however, sufficient data is not available to evaluate the NCCI production expense gradations. This 2.0 point differential may be explained by the lower commission levels associated with involuntary business.

2. The all size of risk analysis, indicates that the production allowance in the rates has exceeded the actual amount expended by stock insurers by 2.0 to 3.0 points of standard premium for calendar years 1986 to 1989. Based on our analysis, it appears that 1.5 to 2.0 points of this difference may be explained by the lower commission levels on involuntary business. The remaining difference is due to: (1) the expense gradations and (2) the fact that some stock carriers use the non-stock premium discount table.

3. NCCI should perform an annual production expense review based on direct experience similar to the current NCCI general expense review in order to establish production expense provisions. However, in order for NCCI to properly perform this review, the production allowances by size of risk need to be verified. Therefore, NCCI should collect all production expenses in the 1991 call for expenses by size of risk. In October of 1991, NCCI will have the required experience on the servicing carrier allowance to adjust other acquisition expenses to a direct basis.

EXPENSES

EXPENSES

VIII. OBJECTIVE 2e: JUSTIFICATION FOR DUAL EXPENSE DISCOUNTS

This section addresses the following objective from the RFP:

Objective (2e) Expenses - Examine whether the original assumptions which supported the existence of dual expense discounts still exist. What is the relationship between the higher rates collected by insurers utilizing non-stock discounts and their level of policyholders' dividends? Are the insurers utilizing non-stock premium discounts realizing lower expenses, and, if so are the "savings" being returned in the form of higher dividends.

A. Dual Expense Program

NCCI publishes two premium discount tables:

1. A stock table; and
2. A non-stock table.

The two tables are reproduced below along with the average implied discount trended to a January 1, 1992 distribution of policies by size of risk.

<u>Standard Premium Division</u>	<u>Stock Premium Discounts</u>	<u>Non-Stock Premium Discounts</u>
First \$ 5,000	0.0%	0.0%
Next \$ 95,000	10.9	3.5
Next \$400,000	12.6	5.0
Next \$500,000	14.4	7.0
Average Discount	10.4%	4.1%

EXPENSES

The stock premium discount table is based on the 1982 study of general and other acquisition expenses by size of risk and an assumed production expense gradation by premium size interval. The non-stock premium discounts were selected judgmentally by the Actuarial Committee in 1984 based on the 1982 study which created the stock table and the perceived dividend differential between stock and non-stock companies. The discounts have not been changed since 1984.

B. Stock Versus Mutual Dividend Ratios

It appears that the difference in dividend ratios between stock and mutual companies is disappearing. Exhibit 44 displays countrywide incurred dividend ratios (incurred dividends divided by net earned premium) for calendar years 1971 to 1989 for stock and mutual companies along with the difference in the dividend ratio.

The following table displays the mutual and stock dividend ratios for the 1971 through 1983 time period and the 1984 through 1989 time period.

<u>Type of Company</u>	<u>Incurred Average Dividend Ratio</u>	
	<u>1971-1983</u>	<u>1984-1989</u>
Mutual	13.3%	9.2%
Stock	5.8	6.9
Dividend Differential	7.5	2.3

The dividend differential between stock and mutual companies is decreasing.

In addition we analyzed countrywide paid dividend ratios for stock versus mutual companies excluding California. California was excluded because:

1. NCCI does not publish rates or loss costs in California; and
2. A high proportion of the countrywide dividends are attributable to California. California has a minimum rate law for workers compensation which precludes

EXPENSES

company deviations and other rating plans that reduce premium. Therefore, price competition in California takes place largely through dividend payments.

The following table displays the countrywide (excluding California) ratio of paid dividends to direct earned premium for mutual versus stock companies for the 1985-1989 time period.

<u>Calendar Year</u>	<u>PAID AVERAGE DIVIDEND RATIOS</u>		<u>Dividend Differential</u>
	<u>Type of Company</u> <u>Mutual</u>	<u>Stock</u>	
1985	8.9%	6.4%	2.5%
1986	7.3	5.3	2.0
1987	5.9	4.6	1.3
1988	5.1	4.3	0.8
1989	4.1	3.9	0.2
1985-1989	5.9	4.8	1.1

It also appears that the differential in the paid dividend ratio between stock and mutual companies is decreasing.

One possible explanation for the decrease in dividend ratios between stock and mutual companies is the decrease in profitability as reported in the IEE. Exhibit 45 displays a summary of the IEE operating ratios and net income ratio for the 1971-1983 and 1984-1989 time periods for stock versus mutual companies for workers compensation. During the 1971-1983 time period mutual companies reported positive underwriting income and mutual companies paid out 129.3% more in dividends than stock companies. During the 1984-1989 time period mutual companies reported negative underwriting income; therefore, mutual companies had less funds to distribute in the form of dividends. The dividend ratio for mutual companies decreased from 13.3% for the 1971-1983 time period to 9.2% for the 1984-1989 time period. Therefore, the decrease in underwriting income may be one factor affecting the decreasing dividend differential between stock and mutual companies.

EXPENSES

Technical Appendix G displays the IEE operating ratios and underwriting income for mutual and stock companies for calendar years 1971-1989.

C. Dividends and Expenses by Type of Insurer

Exhibit 46 displays the production and general expense ratios for the first \$5,000 of premium for stock and mutual companies for calendar years 1984-1989. The average combined expense ratio for mutuals is 17.4% or 1.3 points lower than the stock ratio of 18.7% adjusted to a January 1, 1992 level. In addition to this differential, the non-stock premium discount tables provide less of a discount than the stock tables. The following table compares the expense levels, premium discount provisions and dividend ratios for stock and mutual companies.

	<u>Percent of Standard Premium</u>		
	<u>Stock</u>	<u>Mutual</u>	<u>Differential</u>
Expenses Needed First \$5,000	18.7%	17.4%	1.3%
Premium Discount	10.4	4.1	6.3
1985 - 1989 Paid Dividend Ratio (excluding California)	4.8	5.9	(1.1)

For the first \$5,000 of premium, mutual companies incur 1.3 points less in expenses than stock companies and in addition mutual companies collect 6.3 points more in premium than stock companies due to the premium discount plan differential. Therefore, all other things being equal, mutuals could pay 7.6 points more in standard premium as dividends than stock companies. However, the paid dividend differential is only 1.1 points for the 1985 to 1989 time period. This analysis does not imply that mutual companies are generating a higher net income than stock companies, as the analysis ignores loss ratio and investment income differences. In fact, as Exhibit 45 displays, stock and mutual companies reported a similar net income (underwriting

EXPENSES

income plus investment income) amount relative to earned premium for the 1984 to 1989 time period.

One further limitation of this analysis is that some stock companies use the non-stock table and some non-stock companies use the stock table. The following table displays the magnitude of the crossover of stock and non-stock companies (based on a NCCI special call):

<u>Type of Insurer</u>	<u>Percentage of Premium Premium Discount Table Used</u>		<u>Total</u>
	<u>Stock</u>	<u>Non-Stock</u>	
Stock	74.8%	25.2%	100%
Non-Stock	18.1	81.9	100%

Below we discuss several points related to the regulatory approval process as respects premium discount tables and dividend plans.

First, state insurance departments (Departments) exercise the same regulatory control over the stock and non-stock discount tables as they do over rates and rating plans. In practice, however, Departments approve the two tables and do not monitor the movement of insurers from the stock to non-stock tables.

In addition, even though all of the applicable business written by an individual insurer is rated using either the stock or non-stock table, different insurers in a group may use different discount tables. NCCI issued a special call which required each individual company to state which table it was utilizing. An insurer operating as a group of companies can change an employer from the non-stock to stock discount tables by moving the employer from one company to another. This process is generally outside the control of the regulatory approval process.

Dividend plans are not subject to the same regulatory requirements as rates and rating plans. In most states, dividend plans are not even filed with the state regulatory authority. However, some states restrict the amount of dividend payments which can

EXPENSES

be made in a calendar year (e.g., typically a percentage of surplus or earned surplus). In addition, dividend payments are not guaranteed; typically the board of directors must make a declaration that a certain amount of dividends can be paid in the next quarter. Thus, Departments cannot regulate the extent in which insurers satisfy the policyholder dividend expectations which might be justified by the difference in discount tables.

D. Conclusions and Recommendations

1. The premium discount differential between stock and non-stock discount tables is 6.3% of standard premium (companies utilizing the non-stock table collect 6.3% more in standard premium than companies utilizing the stock table); whereas, the paid dividend differential for the 1985-1989 time period is only 1.1% of premium. Therefore the differential between the stock and non-stock table is not justified solely based on dividend differences; however, stock and mutual company profitability, net of dividends to policyholders, appears similar. NCCI should review mutual and stock expense experience by size of risk in order to determine expense graduations and therefore, a premium discount table for each type of insurer.
2. There appears to be a correlation between the IEE reported underwriting income of mutual companies and their level of policyholder dividends. During periods when underwriting income is positive, mutual companies distribute more funds through policyholder dividends than during periods when their underwriting income is negative.

EXPENSES

IX. OBJECTIVE 2f: EQUITY OF PREMIUM DISCOUNT PROGRAMS AND EXPENSE CONSTANTS

This chapter addresses the following objective of the RFP:

Objective (2f) Expenses - Review premium discounts (stock and non-stock) and expense constants to determine whether the relative expense loadings are equitable for all sizes of risk.

The current NCCI premium discount and expense constant programs are based on the 1982 study of stock company expenses by size of risk (1982 study). This section discusses the nature of the study and the conclusions of the study as they relate to the present NCCI expense program. We will first describe the 1982 study and then we will review the conclusions reached by NCCI. In addition, we will review the mutual companies expenses by size of risk.

A. 1982 NCCI Expense Study by Size of Risk

NCCI issued a special call (1982 call) to obtain expense data by size of risk, function and type for calendar year 1982. The prior call collected 1977 expense data. A call for 1991 expense data by size of risk was recently authorized by the NCCI Actuarial Committee (Committee).

The 1982 call applied to individual insurers and or groups writing \$50 million or more of workers compensation direct earned premium in calendar year 1982. These insurers reported the distribution of salaries and expenses for workers compensation business by size of risk. Premiums and expenses were reported on a direct basis with respect to reinsurance. The following expense items were reported by size of risk:

- Other acquisition
- Payroll Audit
- Inspection

EXPENSES

- Other general
- Boards and Bureaus

Exhibit 47 presents the NCCI data reporting form. The expense elements on the form were reported on an incurred basis with the totals reconcilable to the IEE. NCCI instructed companies to allocate expenses by size of risk using any method which the company believed would provide the most accurate allocation of expenses by size of risk. The method need not be the same method the company used to allocate expenses to line of business.

NCCI analyzed stock company general expense data in order to determine:

1. The general expense component of the expense constant; and
2. The general expense gradations by size of risk.

The general expense gradations are combined with the assumed production expense gradations to derive the premium discount table. Based upon regression analysis of the data, NCCI staff recommended the following general expense program.

Expense Constant - General Expense Element \$62.63

<u>Standard Premium Division</u>	<u>General Expense Provisions</u>
First \$ 5,000	7.5%
Next 20,000	5.5
Next 75,000	4.8
Next 900,000	4.2
Over 1,000,000	3.1

The 1982 study did not incorporate commission and brokerage expenses; only other acquisition expense was captured in the 1982 study. The staff recommended an expense constant attributable to other acquisition expenses of \$35.49 based on

EXPENSES

regression analysis, using data for policies generating less than \$5,000 in standard premium.

The NCCI staff selected the following table of production expense provisions by premium division.

<u>Standard Premium Division</u>	<u>Production Expense Provisions</u>
First \$ 5,000	15.0%
Next 20,000	7.5
Next 75,000	7.5
Next 900,000	6.0
Over 1,000,000	6.0

There is no NCCI documentation for the particular production expense provision by standard premium division, although the divisions are the same as the general expense divisions.

The overall premium discount table is calculated from the above general expense and production expense allowances. The calculation of the premium discount for an interval is the sum of the production and general expense difference between the interval and the first \$5,000 divided by one minus the average tax provision and profit and contingency margin.

The following table displays the indicated premium discount provision for the premium interval \$20,000 excess of \$5,000 assuming a tax provision of 4.24% and a profit and contingency margin of 2.5%.

EXPENSES

PREMIUM DISCOUNT CALCULATION

1. General Expense Provision - First \$5,000	7.5%
2. General Expense Provision - Next \$20,000	<u>5.5</u>
3. General Expense Gradation (1) - (2)	2.0%
4. Assumed Production Expense Provision - First \$5,000	15.0%
5. Assumed Production Expense Provision - Next \$20,000	<u>7.5</u>
6. Production Expense Gradation (4) - (5)	7.5%
7. Production and General Expense Gradation (3) + (6)	9.5%
8. 1.00 - (Tax and Profit Margin)	.933
9. Indicated Premium Discount (7) / (8)	10.2%

Of the 10.2% indicated premium discount, more than 75% (7.5%/9.5%) relates to production expense gradations. This shows the significance of the production expense gradation in determining the premium discount provision. We recommend that NCCI collect all production expense experience (including commission and brokerage) by size of risk in order to determine the appropriateness of the premium discount table.

The NCCI staff recommended the following premium discount table based on the aforementioned gradations and methodology

NCCI Staff Recommended Premium Discount Table

<u>Standard Premium Division</u>	<u>Premium Discount</u>
First \$ 5,000	0.0%
Next 20,000	10.2
Next 75,000	11.0
Next 900,000	13.2
Over 1,000,000	14.4

EXPENSES

The NCCI Actuarial Committee (Committee) concluded that the cost of changing the premium discount division points as a result of the 1982 study was higher than warranted in light of the variability in the underlying data. The Committee decided to retain the then current premium discount division breakpoint at \$5,000, \$100,000, and \$500,000, and selected the following general expense provisions by premium division.

Stock: General Expense Provisions by Premium Division

<u>Standard Premium Division</u>	<u>General Expense Provisions</u>
First \$ 5,000	7.5%
Next 95,000	4.9
Next 400,000	4.7
Over 500,000	3.1

The committee did not alter the recommended general expense constant of \$62.63, the other acquisition expense constant of \$35.49 or the overall expense constant of \$120. The calculation of the \$120 overall expense constant from the general expense and other acquisition expense components is shown on Exhibit 48.

Based on the general expense and production provisions by premium discount division, the premium discounts for stock companies were calculated to be:

Stock: Premium Discount Table

<u>Standard Premium Division</u>	<u>Premium Discount</u>
First \$ 5,000	0.0%
Next 95,000	10.9
Next 400,000	12.6
Over 500,000	14.4

EXPENSES

Based on qualitative consideration of the stock company discounts and the Committee's perception of the relationship between stock and non-stock company dividend plans, the following non-stock discounts were selected judgmentally by the Committee.

Non-Stock: Premium Discount Table

<u>Standard Premium Division</u>	<u>Premium Discount</u>
First \$ 5,000	0.0%
Next 95,000	3.5
Next 400,000	5.0
Over 500,000	7.0

As we discussed in Section VIII, it appears that the dividend differential between stock and non-stock companies is disappearing. Therefore NCCI should analyze stock and non-stock expense experience by size of risk to determine the appropriateness of the current premium discount tables.

B. Evaluation of the Expense Provisions by Size of Risk

To evaluate the Committee's recommended general expense program filed April 1, 1985 as a result of the 1982 study, we compared the general expenses incurred per policy versus the recommended general expense provision in the risk's premium by premium size interval. This analysis considers:

1. the expense constant,
2. the variable loading for the first \$5,000 of premium and the premium discount plan.

EXPENSES

The average incurred general expenses for stock companies completing the 1982 call is displayed in Column (8) of Exhibit 49 by premium size interval. For example, for the premium size interval \$200 to \$299 on average companies incurred \$82.57 in general expenses in calendar year 1982. The NCCI recommended general expense provisions are displayed in Column (9) of Exhibit 49. The recommended general expense provision is \$78.31 for the \$200 to \$299 premium size interval. In other words the risk's premium includes a general expense provision of \$78.31. To measure the overall appropriateness of the general expense program, we divided the general expense difference between the actual expenses incurred and the expense provision in the premium by the average premium size in the interval. Column (10) displays the expense difference and Column (11) displays the difference relative to the average premium in the interval. The following table displays the calculation for the \$200- 299 premium size interval.

ANALYSIS OF GENERAL EXPENSE PROGRAM PREMIUM SIZE INTERVAL (\$200-\$299)

Average Incurred Expenses	\$ 82.57
Expenses Incorporated Into Rates	\$ 78.31
Expense Difference	\$ (4.26)
Average Premium Size	\$ 245.00
Expense Difference Relative to Premium	(1.7)%

For stock companies the NCCI general expense provision (i.e., component of premium) closely approximates the average incurred general expenses by premium size interval except for the smallest premium size interval (\$0 - \$99). The largest percentage difference for any premium size interval (excluding the \$0 - \$99 interval) is 1.7% for the \$200 - \$299 premium size interval. Based on our analysis, for stock insurers, the NCCI general expense program based on calendar year 1982 experience is equitable by size of risk.

We also performed a similar general expense analysis for mutual companies. This analysis will allow us to determine if mutual companies' general expense experience is significantly different than stock companies' general expense experience by size of risk.

EXPENSES

Exhibit 50 is similar to Exhibit 49 but analyzes mutual companies incurred general expenses by premium size interval. As in Exhibit 49, Column (8) displays the average incurred general expenses for mutual companies completing the call. Column (9) of Exhibit 50 displays the general expense provision incorporated into the risk's premium based on the stock general expense gradations. The expense difference, Column (9) minus Column (8) can be utilized to determine if the stock general expense program is appropriate for mutual companies; Column (10) displays the difference. The stock program generates more expense dollars through the rating plan than incurred on average for mutual companies. The largest redundancy relative to premium occurs at the lower premium size intervals. For example, as Column (11) of Exhibit 50 displays, the redundancy relative to premium is 69.3% for the smallest premium size interval and 13.0% for the next largest premium size interval. However, for the larger premium size intervals (above \$5,000) the stock program fits the mutual experience reasonably well with no relative difference greater than 1.0% of premium. The average relative difference excluding premium sizes below \$5,000 is 0.3%.

This analysis indicates that if stock expense levels are utilized for the first \$5,000 of premium then the stock premium discount table reasonably approximates the mutuals general expense experience for the larger premium sizes. However, a lower expense level is indicated for the first \$5,000 of premium for mutuals.

C. Conclusions and Recommendations

1. We recommend that the study by size of risk be updated on a periodic basis. The Committee unanimously approved of issuing the Special Call for expenses by size during 1991. The Committee plans on updating the study during 1992 based on calendar year 1991 expense experience. We concur with the Committee's action and in addition we recommend that the study be updated on a more regular basis than every nine years. Several factors may have altered the expense needs by size of risk including:

- a. Inflation
- b. Distribution of policies by size of risk

EXPENSES

- c. Average policy size
- d. Mechanization - increased automation

2. We recommend that all production expense (commission and brokerage; and other acquisition expenses) data be collected by size of risk. It is not possible to evaluate the appropriateness of the premium discount program without collecting this information.

3. This analysis indicates that the stock general expense provisions for premium sizes above \$5,000 are appropriate for mutual companies; however, the stock provision for the first \$5,000 of premium exceeds the expenses incurred for mutual companies. Presumably mutual companies return the redundant expenses in the form of policyholders dividends. NCCI should review mutual expense experience by size of risk in order to determine the appropriateness of the current non-stock table.

Calculation of Average Discount for General Expenses
Underlying Premium Discount Plan

FOR STOCK COMPANIES

Midpoint of Data	Premium Discount	Regression Output:	
		Constant	-0.028269795
01-Nov-83	0.0219	Std Err of Y Est	0.0002770983
01-Nov-84	0.0229	R Squared	0.9398566549
01-Nov-85	0.0233	No. of Observations	5
01-Nov-86	0.0235	Degrees of Freedom	3
01-Nov-87	0.0246		
		X Coefficient(s)	0.000001642
Projected 01-Jan-92	0.0269	Std Err of Coef.	0.000000239

ASSUMPTIONS:

- (1) Average policy effective date for policies written in 1991 is 1/1/92.
- (2) Data source for discounts is Premium by Size of Policy Call.
Carriers have optional reporting periods: 1/1/87 - 12/31/87
or 7/1/87 - 6/30/88

A survey of the top 10 carriers reporting this Call (representing 58% of premium) revealed that 64.9% of premium was based on a 7/1/87 - 6/30/88 reporting period. A weighted average of the above midpoints (7/1/87 and 1/1/88, respectively) yielded an average midpoint of approximately 11/1/87. The distribution was assumed to be the same for prior years.

Definition of Allocated Loss Adjustment Expenses
Composed by Joint Actuarial/Claims Committees
As of July 31, 1991

Allocated Loss Adjustment Expenses encompass the following costs of a carrier which can be directly allocated to a particular claim:

- (1) Fees of attorneys or authorized representatives where permitted for legal services, whether by outside counsel or staff representative.
- (2) Court, Alternate Dispute Resolution and other specific items of expense such as:
 - Medical examinations of a claimant to determine the extent of the carrier's liability, degree of permanency or length of disability;
 - Expert medical or other testimony;
 - Autopsy;
 - Witnesses and summonses;
 - Copies of documents such as birth and death certificates, medical treatment records;
 - Impartial examinations ordered by Industrial Board;
 - Arbitration fees;
 - Surveillance;
 - Appeal bond costs and appeal filing fees.
- (3) Medical cost containment expenses incurred, whether by an outside vendor or done internally by an employee for the purpose of controlling medical losses, to ensure that only reasonable and necessary costs of services are paid. The expenses include:

- Bill auditing expenses for any medical or vocational services rendered, including hospital bills (inpatient or outpatient), nursing home bills, physician bills, chiropractic bills, medical equipment charges, pharmacy charges, physical therapy bills, medical or vocational rehabilitation vendor bills.
- Hospital and other Treatment Utilization Reviews, including pre-certification/pre-admission, concurrent or retrospective reviews.
- Preferred Provider Organization expenses.
- Medical Fee Review Panel expenses.

(4) Vocational Rehabilitation Evaluation Expense.

(Note: vocational rehabilitation education expenses and income maintenance shall be reported as part of the loss. Actuarial Committee will consider further.)

The following shall not be included as allocated loss adjustment expense:

- (1) Salaries, overhead and traveling expenses of carrier employees, except for employees while doing activities previously listed as allocated expenses.
- (2) Fees paid to independent claims professionals or attorneys, for developing and investigating a claim so that a determination can be made of the cause, extent or responsibility for the injury or disease, including evaluation and settlement of covered claims.
- (3) Expenses which are defined as either an indemnity or medical loss.

DATA CALL #14
ALLOCATION METHODOLOGY SURVEY

For Companies that Allocate Items (8A) and 8B)
Based on Written Premium or Earned Premium

We are interested in a more detailed explanation of the procedures that companies use to allocate items (8A) and (8B) on the Calendar Year Expense Data Call (#14). Item (8A) is Boards and Bureau Expenses and item (8B) is Audit, Inspection and Other General Expenses. Please respond to the following two questions concerning the allocation procedure your company uses by August 15, 1991.

- 1) If your company has branch office in a state and the branch office services one or a few states, are the (8A) and (8B) related expenses for that branch office only allocated to the states serviced? The other possibility is that all the (8A) and (8B) related expenses are combined into a countrywide total and the countrywide total allocated based on earned premium or written premium by state.

Please check the appropriate box below and insert any comments you feel are appropriate.

ALLOCATION METHOD

- a) Branch office (8A) and (8B) expenses only allocated to one or a few states
_____.
- b) Branch office (8A) and (8B) expenses combined into a countrywide total which is then allocated to state based on earned premium or written premium
_____.

COMMENTS:

- 2) If you checked Box (b) above, is it possible for your company to identify the (8A) and (8B) expenses at the branch office level?

Yes _____ NO _____

Name of person completing form: _____

Company Name: _____

Phone Number: _____

NCCI Prepared

1990 ANNUAL EXPENSE REVIEW

Portion of Expense Constant Allocated to Production Expense

FOR STOCK COMPANIES

1. Portion of expense constant for general expenses (1982 Special Call for Expenses by Size of Risk)	\$62.63
2. Portion of expense constant for other acquisition (1982 Special Call for Expenses by Size of Risk)	\$35.49
3. Total expense constant (1) + (2)	\$98.12
4. Profit and contingency	2.50%
5. Countrywide weighted average Premium Taxes (Including premium based Miscellaneous Taxes)	4.23%
6. Factor to adjust expense constant for profit & taxes 1 - (4) - (5)	0.9327
7. Expense Constant reflecting profit and taxes (3)/(6)	\$105.20
8. Factor to estimate revenue generated by expense constant for Production Expense (2)/(7)	0.337

1990 ANNUAL EXPENSE REVIEW

Calculation of Average Discount for Production Expenses
Underlying Premium Discount Plan

FOR STOCK COMPANIES

Midpoint of Data	Premium Discount	Regression Output:	
		Constant	-0.052581498
01-Nov-83	0.0588	Std Err of Y Est	0.0003872921
01-Nov-84	0.0605	R Squared	0.9751937389
01-Nov-85	0.0618	No. of Observations	5
01-Nov-86	0.0624	Degrees of Freedom	3
01-Nov-87	0.0645		
		X Coefficient(s)	0.000003641
Projected 01-Jan-92	0.0698	Std Err of Coef.	0.000000335

ASSUMPTIONS:

- (1) Average policy effective date for policies written in 1991 is 1/1/92.
- (2) Data source for discounts is Premium by Size of Policy Call.
Carriers have optional reporting periods: 1/1/87 - 12/31/87
or 7/1/87 - 6/30/88

A survey of the top 10 carriers reporting this Call (representing 58% of premium) revealed that 64.9% of premium was based on a 7/1/87 - 6/30/88 reporting period. A weighted average of the above midpoints (7/1/87 and 1/1/88, respectively) yielded an average midpoint of approximately 11/1/87. The distribution was assumed to be the same for prior years.

TECHNICAL APPENDIX A
Servicing Carrier Adjustment

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX A**

NCCI, in their October, 1990 general expense review, included a provision for the "allocation of servicing carrier allowance" in determining the indicated general expense levels. This provision is displayed on row (7) of Exhibit 4 for general expenses. In addition, a similar adjustment is made for production expenses and is displayed on row (7) of Exhibit 39. These adjustments are made in order to restate the IEE expense indications to a direct basis. This adjustment is necessary as companies book the service carrier allowance differently on an assumed and ceded basis.

The servicing carriers for the National Workers' Compensation Reinsurance Pool receive an allowance from the Pool to offset the following expenses associated with issuing residual market policies:

1. general expenses;
2. other acquisition expenses;
3. loss adjustment expenses;
4. profit and contingencies;
5. premium based taxes; and
6. loss based taxes.

Commission expenses are not part of the allowance as the Pool directly reimburses the servicing carriers for commission expenses incurred.

In order to compute the servicing carrier allowance adjustment, NCCI staff requested all servicing carriers and a number of other large companies to report to NCCI the booking of the servicing carriers allowance by major expense category on both an assumed and ceded basis. Exhibit A-1 displays the stock company data collected by NCCI along with the NCCI staff's calculation of the servicing carrier allowance for stock companies.

The top part of the exhibit displays the servicing carriers booking by major expense category of the servicing carrier allowance (Column A). The servicing carriers receive the allowance as a fee to offset their expenses and therefore book the allowance as a negative expense. As NCCI collected data from all stock servicing carriers the ceded expense transactions constitute all ceded adjustments related to the servicing carrier allowance. As a technical note, GE represents general expenses; PE represents production expenses; and LAE represents loss adjustment expenses. As

EXPENSES:
TECHNICAL APPENDIX A

the servicing carriers constitute the entirety of the ceded transactions, Column (B) displays the standard earned premiums and losses for all stock companies. Column (C) displays the ceded transactions relative to premium (or losses for LAE) by major expense category.

The middle portion of Exhibit A-1 displays the assumed servicing carrier adjustment. Column (D) displays the sampled companies booking for the assumed share of the servicing carrier allowance by major expense category. Column (E) displays the corresponding standard earned premium and losses for the sampled companies. Column (F) displays the assumed transactions relative to premium (or loss for LAE) by major expense category.

Column (F) less Column (C) is an estimate of the overstatement by major expense category as a result of the companies recording the servicing carrier allowance differently on an assumed and ceded basis. For example, for calendar year 1989 the ceded service carrier allowance associated with production expenses accounted for 1.48% of total market premium; whereas, the assumed servicing carrier allowance for production expenses accounted for 3.18% of the sampled carriers premium. To restate the IEE expenses to a direct basis, the assumed transactions must equal the ceded transactions; therefore, an adjustment (subtraction) of 1.7% of premium to the IEE production expense indication is necessary. For general expenses for calendar year 1989, the ceded service carrier allowance adjustment (1.69%) exceeds the assumed servicing carriers allowances adjustment (1.22%); therefore, to restate general expenses to a direct basis 0.47% of premium is added to the IEE general expense indications.

TECHNICAL APPENDIX B
Test of Proposed General Expense Methodologies

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX B**

In this Appendix, we compare the projected general expense loading using the three models discussed in Section IV and the current NCCI methodology versus the actual general expenses incurred as reported in the IEE (adjusted to a first \$5,000 basis). The projected general expenses are compared to the IEE expenses for calendar years 1989 and 1988.

A. Insight 1989 Indications

This analysis is based on net experience.

It was necessary to adjust the row labelled "Effect of Premium Discount" to be an estimate of the premium discount in effect at 1/1/90 (the average accident date for policies written in 1989). For stock companies, this calculation utilized the NCCI regression equation. The result for 1989 was a premium discount of 2.57%, or .12% lower than the discount assumed for 1991.

Model 1 - Stock Company Results

Using countrywide premium level changes through 1988 and the assumption that premiums and general expenses will both increase 3.8% during 1989, we have recalculated the indicated general expense provision restated to a first \$5,000 basis at the 1989 rate level (Exhibit B-1). The indicated general expense provision is an average of the 1984-1987 adjusted general expense ratios.

The indicated general expense provision based on this procedure restated to a first \$5,000 basis is 6.42%. This is the result of averaging the four years shown on Exhibit B-1. This indication is compared to the actual 1989 IEE results:

Reported IEE General Expenses excluding Expense Constant Revenue	\$ 793,981
Standard Earned Premium excluding Expense Constant Revenue	<u>22,017,558</u>
General Expense Provision net of Carrier Allowance and Premium Discount Plan	3.61%
Average Discount underlying Premium Discount Plan	2.57
Adjustment for Allocation of Servicing Carrier Allowance	<u>.50</u>
Provision for General Expenses, first \$5,000 basis	<u>6.68%</u>

EXPENSES:
TECHNICAL APPENDIX B

The general expense provision based on trending expenses and adjusting premium to current rate level yielded an expense provision of 6.42%, a result which proved to be deficient by .26%. By comparison, NCCI recommended general expense provision for 1989 (1988 expense review) was 6.7%, a redundancy of .02%.

Model 2 - Stock Company Results

Using countrywide premium level changes through 1988 and the assumption that premiums will increase 3.8% during 1989 (estimated payroll growth), we have recalculated the general expense provision restated to a first \$5,000 basis at the 1989 rate level (Exhibit B-2). Adjusting premiums to current rate level while not trending general expenses implies that the general expense trend is equal to the payroll trend

This model yielded an expense provision of 6.08%, a result which proved to be deficient by .60%.

Model 3 - Stock Company Results

This model is based on the method used by the Workers' Compensation Rating and Inspection Bureau of Massachusetts to establish general expense levels. The indicated general expense provision restated to a first \$5,000 basis at a 1989 rate level is 6.22%, a result which proved to be deficient by .46% (Exhibit B-3).

B. Hindsight 1988 Indications

Note that it was necessary to adjust the row labelled "Effect of Premium Discount" to be an estimate of the premium discount in effect at 1/1/89 (the average accident date of policies written in 1988). For stock companies, this calculation utilizes a regression procedure similar to that used by NCCI to estimate the 1991 discount. The result for 1988 was a premium discount of 2.48%, or .21% lower than the discount assumed for 1991.

**EXPENSES:
TECHNICAL APPENDIX B**

Model 1 - Stock Company Results

The assumption that premiums and general expenses will both increase 3.8% during 1988, was used. The Model 1 indicated general expense provision restated to a first \$5,000 basis is 6.40%. This is the result of averaging the three years shown on Exhibit B-4. This indication is compared to the actual 1988 IEE results (restated to a first \$5,000 basis):

Reported IEE General Expenses excluding Expense Constant Revenue*	\$ 779,167
Standard Earned Premium excluding Expense Constant Revenue*	<u>20,108,586</u>
General Expense Provision net of Carrier Allowance and Premium Discount Plan	3.87%
Average Discount underlying Premium Discount Plan	2.48
Adjustment for Allocation of Servicing Carrier Allowance	<u>.08</u>
Provision for General Expenses, first \$5,000 basis	<u>6.43%</u>

*Adjusted to account for a \$120 expense constant
+Based upon actual 87-88 premium distribution

Our recommended general expense provision based on trending expenses and adjusting premium to current rate level yielded an expense provision of 6.40% - a result which provided to be deficient by .03% (Exhibit B-4). By comparison, NCCI recommended general expense provision for 1988 (1987 expense review) was 7.5% - a redundancy of 1.07%.

Model 2 - Stock Company Results

The assumption that premiums will increase 3.8% during 1988 was used. The indicated Model 2 general expense provision restated to a first \$5,000 basis is 5.99% (Exhibit B-5). This is the result of averaging the three years shown on Exhibit B-5.

The general expense provision of 5.99% proved to be deficient by .44%. By comparison, NCCI recommended general expense provision for 1988 was 7.5% - a redundancy of 1.07%.

EXPENSES:
TECHNICAL APPENDIX B

Model 3 - Stock Company Results

This model is based on the method used by the Workers' Compensation Rating and Inspection Bureau of Massachusetts. The indicated general expense provision restated to a first \$5,000 basis at 1988 rate level is 6.49% (Exhibit B-6). The general expense provision proved to be redundant by .06%.

The following table summarizes the hindsight analysis.

	Recommended General Expense Provision				Actual General Expense Provision
	NCCI	Model 1	Model 2	Model 3	
1989	6.70%	6.42%	6.08%	6.22%	6.68%
1988	7.50%	6.40%	5.99%	6.49%	6.43%

TECHNICAL APPENDIX C
Collected Versus Actual Production and General Expenses

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX C**

To test the adequacy of NCCI's allowance for production and general expenses in the rating plan, we have compared the historical NCCI recommendations for expense provisions versus the amount that the carriers actually incurred as reported in the IEE.

To obtain the recommended provisions, we calculated:

- a. the portion of the overall provision attributable to the expense constant; and
- b. the average variable provision for all policy sizes.

This comparison was done for both general and production expenses using stock company data only. The following sections develop our comparisons for calendar year 1986. Exhibit C-1 summarizes our results for all years in which the available data allowed for a comparison for general and production expenses combined.

EXPENSES:
TECHNICAL APPENDIX C

I. GENERAL EXPENSES

1. Recommended Provision

- a. The expense constant provision was calculated by multiplying the number of policies in a year by the NCCI recommended expense constant. This product was then adjusted to reflect the portion of the total expense constant dollars which can be attributed to general expenses. Note that on Exhibit C-2 we have shown two different expense constant calculations. The first one utilizes a \$120 expense constant which was recommended by the Actuarial Committee in the NCCI annual expense review (Method 1). The second method utilizes a weighted average of the expense constants actually in effect for each state for the year (Method 2). The following calculations derive these provisions:

**EXPENSES:
TECHNICAL APPENDIX C**

	Method 1	Method 2
1986 Number of Policies	2,058,050	2,058,050
Expense Constant	120	88.3
Expense Constant Revenue (ECR)	246,966,000	181,725,815
Portion of ECR Attributable to General Expense (GE)	.595	.595
ECR Attributable to GE	146,944,770	108,126,860
1986 Direct Earned Premium (000's)	17,545,256	17,545,256
Provision for Expense Constant Portion of General Expenses	0.84%	.62%

- b. The average variable provision for all policy sizes is derived directly from the stock premium discount table and policy size distribution:

Premium Size	Percentage of Premium	Gradation of General Expense Provisions
0-5,000	24.06%	7.5%
5,001-100,000	39.98	4.9
100,001-500,000	16.99	4.7
500,000 & Over	18.97	3.1
		5.15%

- c. Combining the two portions above gives us the NCCI recommended general expense provision:

EXPENSES:
TECHNICAL APPENDIX C

	Method 1	Method 2
Provision for Expense Constant (EC)	.84%	.62%
Average Provision net of EC	5.15	5.15
NCCI Recommended General Expense Provision	5.99%	5.77%

This analysis does not reflect the premium written by stock companies utilizing the non-stock premium discount table.

2. Actual Company Expenses Incurred

As previously mentioned, this calculation is taken directly from the countrywide IEE's. The following calculation derives the amount of general expense actually incurred (including revenue generated from the expense constant):

1986 General Expenses Incurred (000's)	795,797
1986 Direct Earned Premium (000's)	17,545,256
Actual 1986 General Expense Provision	4.54%

**EXPENSES:
TECHNICAL APPENDIX C**

II. PRODUCTION EXPENSES

1. Recommended Provision

- a. As was done for General Expense, the expense constant provision was calculated by taking the number of policies in a given year and multiplying by the NCCI recommended expense constant. This product was then adjusted to reflect the portion of the total expense constant dollars which can be attributed to production expenses.

	Method 1	Method 2
1986 Number of Policies	2,058,050	2,058,050
Expense Constant	120	88.3
Portion of ECR Attributable to General Expense (GE)	.337	.337
ECR Attributable to GE	83,227,542	61,241,600
1986 Direct Written Premium (000's)	17,853,256	17,853,256
	.47%	.34%

- b. The average variable provision for all policy sizes is derived directly from the stock premium discount tables and policy size distribution.

**EXPENSES:
TECHNICAL APPENDIX C**

Premium Size	Percentage of Premium	Gradation of Production Expense Provisions
0-5,000	24.06%	15.0%
5,001-100,000	39.98	7.5
100,001-500,000	16.99	6.0
500,000 & Over	18.97	6.0
		8.76

- c. Combining the two provisions above gives us the NCCI recommended production expense provision:

	Method 1	Method 2
Provision for Expense Constant (EC)	.47%	.34%
Average Provision Net of EC	8.76	8.76
NCCI Recommended General Expense Provision	9.23%	9.10%

2. Actual Company Expense Incurred

As with the case for general expenses, this calculation is taken directly from the countrywide IEE's. The following calculation derives the amount of production expense actually incurred (including revenue generated from the expense constant):

1986 Production Expenses Incurred (000's)	\$ 1,494,991
1986 Direct Written Premium (000's)	17,853,256
Actual 1986 Production Expense Provision	8.37%

**EXPENSES:
TECHNICAL APPENDIX C**

III. CONCLUSIONS

The summary of our results can be seen on Exhibits C-2 (for general expense) and C-3 (for production expense) for calendar years 1986 through 1989. Both exhibits display that the rating plan premium collected for expenses as recommended by NCCI exceed the amount actually incurred by the companies.

For production expenses, this analysis does not reflect:

1. the premium written by stock companies utilizing the non-stock premium discount table; and
2. the filed assigned risk expense provision where NCCI prepares a separate assigned risk filing.
3. The distortion due to the way the carriers book the servicing carrier allowance (Appendix A).

As we discuss in Technical Appendix G, the net effect of the above two factors is to increase the stock collected expense provision.

TECHNICAL APPENDIX D
Correlation Test of State Expense Ratios

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX D**

This Appendix presents an explanation of the statistical correlation tests which were performed to measure the relationship of state expense ratios.

The two statistical tests mentioned below measure the correlation of expense ratio rankings across years within a state. Both the production and general expense ratios were computed on a direct basis and are restated to a first \$5,000 basis. General expenses and production expenses were tested separately for each correlation statistic. The two statistical tests of correlation utilized are:

1. A chi-squared test based on the coefficient of concordance; and
2. A normal test based on Spearman's rank correlation coefficient.

The coefficient of concordance W ranges in value from 0 to 1. The variable permits a simultaneous test across a multiple number of years m of the degree of correlation in the rankings of n objects.

The execution of the test is best described by the use of an example. Exhibit D-1 provides the calculation of the coefficient of concordance for production expenses. The first step is to take the rank for production expenses for each state in each of the three years 1987 through 1989 and sum across the years. For example, the sum of Utah's ranks across the three years is 5. With $m = 3$ years and $n = 37$ states, the average three-year sum of the ranks is $m(n+1)/2 = 3(37+1)/2 = 57$; in the next step, this average is subtracted from each state's own three-year summed rank to determine each's state's deviation. Again focusing on Utah, the deviation is $5-57 = -52$. Then, the deviations are squared and the squares are summed across the states; this gives the sum of the squared deviations $S = 31,878$ that is shown on Exhibit D-1. This sum includes the squared deviation for Utah of $(-52)(-52) = 2,704$.

We now define M as the square of m and $N = n(n+1)(n-1)$; The coefficient of concordance can now be calculated from the equation $W=12S/MN$. In this case, $M = 9$ and $N = 37(37+1)(37-1) = 37(38)(36) = 50,616$; it follows that the value of the test statistic is $12(31,878)/9(50,616) = .839734$; this result is also displayed on Exhibit D-1.

EXPENSES:
TECHNICAL APPENDIX D

Although tables of the distribution of W are available, it is useful to exploit the relationship of W to the chi-squared distribution in hypothesis testing. The transformation of W based on $f(W) = m(n-1)W$ produces a variable that is approximately a chi-squared variable, with $n-1$ degrees of freedom. For our rankings of $n = 37$ states in each of $m = 3$ years, the test value $f(W)$ produced is $3(37-1)(.839734) = 90.6913$.

The coefficient of concordance tests the null hypothesis that there is no consensus in the rankings year to year (no community of order). Based on the transformation to chi-squared, the critical test value with $n-1 = 37-1 = 36$ degrees of freedom is 61.5 at a .005 level of significance. Thus, for the production expenses, the null hypothesis is rejected in favor of the alternative hypothesis: the state rankings for production expenses are correlated year to year for the entire three-year period 1987 to 1989.

Exhibit D-2 repeats the coefficient of concordance test for general expenses. The key values resulting from this test are: $S = 29,828$, $W = .785733$, and $f(W) = 84.8592$. At the .005 level of significance, the determination is again to reject the null hypothesis in favor of the alternative hypothesis: the state rankings for general expenses are correlated for the entire three-year period 1987 to 1989.

Our second set of tests involved the calculation of Spearman's rank correlation coefficient $r(s)$. These tests are based on the more familiar concept of correlation being a statistical measure applied to exactly two sets of observations. That is, whereas the coefficient of concordance W permits a test of a multiple number of years, Spearman's rank correlation coefficient tests one year against another. As a correlation coefficient, the range of values for $r(s)$ is -1 to 1.

As before, the calculation of Spearman's $r(s)$ statistic can best be explained through use of an example. Exhibit D-3 presents the calculation of $r(s)$ for each of the three possible year against year combinations (i.e., 1987 versus 1988, 1988 versus 1989, 1987 versus 1989) for the rankings of state production expense ratios. The first step in calculating $r(s)$ is to calculate the difference in each state's rankings across the two years being compared, then to square these differences; for example, Utah ranks in 1987 and 1988 are 1 and 2, respectively, resulting in a squared difference of 1. The squared differences are then summed across states; for the comparison between 1987 and 1988, it is seen on Exhibit D-3 that the squared differences sum

**EXPENSES:
TECHNICAL APPENDIX D**

to $D = 2,582$. Spearman's $r(s)$ is then calculated from the equation $r(s) = 1 - (6D/N)$, where N is again defined to be $N = n(n+1)(n-1)$, and n is again the number of states being ranked. In the case of 1987 versus 1988 production expense rankings, $r(s) = 1 - [(6)(2,582)/50,616] = .6939$, again as displayed on Exhibit D-3.

Although tables of the distribution of $r(s)$ are available, it is useful to exploit the relationship of $r(s)$ to the standard normal distribution in hypothesis testing. The transformation of $r(s)$ based on $g(r(s)) = .5\{\ln[(1+r(s))/(1-r(s))]\}$ produces a variable that is approximately normal, with variance $1/(n-3)$. In this case, the variance is $1/(37-3) = .0294$, which implies a standard deviation of $.1715$; this can be used to further transform the normal variable $g(r(s))$ to a standard normal variable Z .

For the case of 1987 versus 1988 production expense rankings, $g(r(s)) = 0.8554$. This corresponds to the standard normal variate of $Z = 0.8554/.1715 = 4.9878$ that is displayed on Exhibit D-3. The test of the null hypothesis that there is zero correlation in the rankings then reduces to a comparison of this value against a critical standard normal Z value. At a $.005$ level of significance, the critical value of Z is 2.57 for a one-sided test; hence, the test is significant. Thus, for the correlation of production expenses between 1987 and 1988, the null hypothesis is rejected in favor of the alternative hypothesis: the rankings are positively correlated.

Exhibit D-3 also displays tests of 1988 versus 1989 and 1987 versus 1989 for production expenses. Additionally, Exhibit D-4 displays tests of all three possible year against year tests for the general expense ratio rankings. In all of these remaining cases, the test results are significant; at the $.005$ level of significance, the determination is always made to reject the null hypothesis in favor of the alternative hypothesis that the state rankings are positively correlated year to year.

EXPENSES

TECHNICAL APPENDIX E
Residual Market Producer Fees

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX E**

NCCI publishes producer fee tables by state for non-coal and coal exposures for residual market business. Exhibit E-1 displays the tables utilized by state. NCCI publishes 12 different tables for non-coal exposures and 1 table for coal mine exposures. The attached Exhibits E-2 through E-13 display the various tables.

The tables provide for lower producer fees than would be incurred in the voluntary market. Based on our analysis of stock companies, we estimated that companies incurred 13.0% of standard premium (excluding expense constant revenue) for total production expenses (including other acquisition expenses) for the first \$5,000 of standard premium. Based on our analysis, we estimate that 4.5% of the 13.0% is for other acquisition expenses and 8.5% is due to commission related expenses.

All of the residual market producer fee tables provide for producer fees less than 8.5% for the first \$5,000 of standard premium. For example, Table A (Exhibit E-2) contains the following graduated producer fee schedule:

Residual Market Producer Fee

Table A

<u>Standard Premium Division</u>		<u>Producer Fee Provision</u>
First	\$1,000	8.0%
Next	\$4,000	5.0
Next	\$95,000	3.0
Over	\$100,000	2.0

The above table provides for a 5.6% producer fee allowance for the first \$5,000 of standard premium.

Please note: The percentages given take into account the current Louisiana rule against paying producer fee on the surcharged portion of the premium, and therefore should be applied against the state standard premium as per the usual procedure.

Effective October 1, 1984

Exhibit E-11

5% FLAT

A flat producer fee of 5% of the total charged and collected premium is used in the states of:

Arizona
North Carolina

1% FLAT

A flat producer fee of 1% is applied to the total charged and collected premium for the **occupational disease coverage** under policies subject to the Federal Coal Mine Health and Safety Act in the states of:

Alabama	Missouri
Alaska	Montana
Arizona	New Mexico
Arkansas	North Carolina
Colorado	Oklahoma
Georgia	Pennsylvania
Illinois	South Dakota
Indiana	Tennessee
Iowa	Utah
Kansas	Virginia
Kentucky	Washington
Maryland	Wyoming

The producer fee tables applicable to the **surface and auger traumatic coverage** and **underground traumatic coverage** under policies subject to the Federal Coal Mine Health and Safety Act in the above states are the same as the non-coal tables. Refer to Part Seven, Exhibit E, Page 1 for the appropriate Non-Coal table.

Effective May 1, 1982

EXPENSES

TECHNICAL APPENDIX F

Net Production Allowance in the Rating Plan - Calendar Year 1989

EXPENSES

**EXPENSES:
TECHNICAL APPENDIX F**

NCCI manual rates incorporate a 15% loading for production expenses for the first \$5,000 of standard premium and the percentage loading decreases, as the premium size increases. The following table displays the production allowances for various premium sizes for companies electing the stock premium discount table.

Division of Premium	Stock Production Expense Allowances
First \$5,000	15.00%
Next 95,000	7.50
Next 400,000	6.00
Next 500,000	6.00

These provisions, along with the production expense component of the expense constant of \$47.35 provide for the production allowance in the rating plan.

Based on the distribution of policies by size (from data call #7) and the above table, we can derive the average variable production expense allowance which is provided for in the rating plan. Exhibit F-1 displays the premium discount associated with production expenses based on data call #7 for five time periods along with NCCI projected discount to January 1, 1992. Using a similar method to NCCI, we computed an average discount of 6.65% as of July 1, 1989. July 1, 1989 is the mid-point for calendar year 1989. Thus the variable expense element in the rating plan for stock companies is 15.00% minus 6.65% or 8.35% for calendar year 1989.

In order to estimate the variable percentage collected by stock companies through the rating plan in calendar year 1989 two additional adjustments are necessary:

1. to reflect the premium written by stock companies utilizing the non-stock table; and
2. to reflect the lower filed commission allowances in manual rates for residual market business in some states.

EXPENSES:
TECHNICAL APPENDIX F

A stock company is not restricted to utilizing the stock table. Based on a special data call by NCCI, 74.8% of the stock companies utilize the stock table and 25.2% of the stock companies utilize the non-stock table. The stock companies utilizing the non-stock table will collect more for production expenses than stock companies utilizing the stock table. For the states in which NCCI manages the residual market pool, the residual market premium represents 22.0% of the calendar year 1989 total market premium and the average production allowance for the first \$5,000 of standard premium is 14.25% (Exhibit F-2). Exhibit F-3 displays the filed production expense allowance for residual market business in states where NCCI submits a separate filing for residual market business. As discussed in Technical Appendix E, in general the producer fees for residual market business are lower than the voluntary commission and brokerage expenses incurred by companies.

Based on the above information, we can estimate the average variable production allowance (excluding expense constant revenue) for the total market based on the Actuarial Committee's recommended expense program for policies effective in 1989 and the residual market information above. The following table displays the calculation.

Stock Companies		
Type of Business	Percentage of Premium Related to Total Market	Average Production Allowance Adjusted to 1989 Distribution
Voluntary		
Stock Using Stock Table	58.3%	8.35%
Stock Using Non-Stock Table	19.7	11.65
Sub Total	78	9.18
Residual Market	22	8.72
Total	100	9.08

Based on the above analysis, the average collected production expense allowance of 9.08% exceeds the incurred production expense allowance of 6.03% by 3.05 points of standard premium. The incurred production expense allowance is directly from the IEE (less expense constant revenue associated with production expenses).

1990 ANNUAL EXPENSE REVIEW

Calculation of Average Discount for Production Expenses
Underlying Premium Discount Plan

FOR STOCK COMPANIES

Midpoint of Data	Premium Discount	Regression Output:	
		Constant	-0.052581498
01-Nov-83	0.0588	Std Err of Y Est	0.0003872921
01-Nov-84	0.0605	R Squared	0.9751937389
01-Nov-85	0.0618	No. of Observations	5
01-Nov-86	0.0624	Degrees of Freedom	3
01-Nov-87	0.0645		
Projected 01-Jan-92	0.0698	X Coefficient(s)	0.000003641
		Std Err of Coef.	0.000000335

ASSUMPTIONS:

- (1) Average policy effective date for policies written in 1991 is 1/1/92.
- (2) Data source for discounts is Premium by Size of Policy Call.
Carriers have optional reporting periods: 1/1/87 - 12/31/87
or 7/1/87 - 6/30/88

A survey of the top 10 carriers reporting this Call (representing 58% of premium) revealed that 64.9% of premium was based on a 7/1/87 - 6/30/88 reporting period. A weighted average of the above midpoints (7/1/87 and 1/1/88, respectively) yielded an average midpoint of approximately 11/1/87. The distribution was assumed to be the same for prior years.

I. INTRODUCTION

This component of Milliman & Robertson's examination of the ratemaking procedures used by National Council on Compensation Insurance (NCCI) focuses on trend. This analysis was prepared in response to a request from the National Association of Insurance Commissioners (NAIC). The questions asked by the NAIC are included in italics at the beginning of each section.

In ratemaking, historical experience is used to project the loss ratios expected for the period during which rates will be in effect (the rate effective period). Due to the time necessary to compile the historical experience, prepare rate filings, and, where necessary, gain regulatory approval, two to three years can elapse between the historical experience period and the rate effective period. During that time, many factors can influence loss ratios, including:

- differences between medical and wage inflation,
- changes in the utilization of medical services,
- changes in claim frequency, and
- shifts in frequency between types of injuries.

The purpose of trend is to measure these changes and to include a provision in the rate level for anticipated changes between the experience period and the rate effective period.

TREND

II. SUMMARY AND CONCLUSIONS

Most of our analysis focused on a review of the experience in eight sample states: Connecticut, Florida, Illinois, Louisiana, Michigan, North Carolina, Oregon and Wisconsin. The experience for Oregon was provided separately for private companies and the state fund. While we have drawn inferences from the experience in these states, conclusions regarding appropriate methods should be validated through an analysis of the experience in all states. The evaluation of the linear and exponential models included one test based on all NCCI states excluding Georgia. It should also be noted that variations in some aspects of the trend procedure may be appropriate for a particular state to reflect the specific circumstances in that state.

A. Evaluation of NCCI Procedure (Section 3a)

"Are there any expected biases or errors present in the NCCI's general trending procedures? If so, discuss their impact."

We have evaluated each aspect of the NCCI trend procedure. Based on our review of trend indications in the sample states, there appear to be several aspects that may produce inaccuracies in the rate level indication. These are:

- the use of the midpoints of the experience and rate effective periods as approximations for their respective average accident dates,
- the use of credibilities that do not consider the appropriateness of the credibility complement, and
- the split between effective and ineffective medical fee schedules based on observed trend indications.

Two other potential biases related to the benefit on level factor derivation were identified by the NAIC. These are discussed in detail in Sections VII and IX of this report.

TREND

1. Midpoint versus Average Accident Date (Page 34)

In most states, the midpoints of the rate effective period and the experience period used for ratemaking are reasonable approximations of the average accident date in each period. In some states, however, presence of a state fund with a highly skewed distribution of premium writings by month can cause errors in the loss ratio projected for the rate effective period of up to 2%, using a 7% annual trend rate. These errors can lead to either over- or understatement of the projected loss ratios. We recommend that adjustments be made to the lengths of the trend periods to reflect distributions of premium writings by month.

2. Introduction of Exponential Curve (Page 54)

Based on the results of tests of projection accuracy, we conclude that for medical losses the exponential model was more accurate than the linear model for the relatively recent economic environment (using Policy Years 1981 through 1986 to project Policy Years 1987 and 1988). For indemnity losses, the corresponding results were inconclusive, but tended to favor the exponential model. Our limited tests using different time periods, reflecting a range of economic conditions, were inconclusive for both medical and indemnity losses. We believe that it is important that, before a model is adopted for long-term use, it be shown to perform better under a range of conditions, not only those that have existed recently. We therefore recommend that NCCI perform tests similar to those contained herein periodically (every two years), which will reflect the then most recent economic environment. We also recommend that NCCI perform tests of projection accuracy over a longer time frame (i.e., five policy years of data predicting two and three years ahead, but differing five-year periods).

3. Appropriateness of the Credibility Complement (Page 56)

In the classical credibility technique employed by NCCI, a weighted average between state trend indications and a credibility complement (based on experience from state groups) is used to determine trend. The weights (i.e. credibilities) are calculated based on the goodness-of-fit of state indications without considering the accuracy of the credibility complement. The resulting weights may be far from optimal.

TREND

We used "empirical Bayesian credibility" methods to test the appropriateness of the credibility complements used by NCCI. These tests indicated that the NCCI procedure has overstated the weight that should be applied to the credibility complement (i.e., understated the state credibility). We also performed tests of prediction errors related to the credibility complement, with inconclusive results. These tests are discussed further on Page 7.

4. Effective versus Ineffective Medical Fee Schedules (Page 71)

NCCI splits states with medical fee schedules between those that are deemed effective and those that are deemed ineffective based on the trend rates indicated after the fee schedule has been implemented. Trend indications from those states with ineffective fee schedules are combined with those from states with no fee schedule in determining the credibility complements.

It is more appropriate to identify the characteristics of fee schedules that are likely to affect trends and to validate these based on the actual data. If such characteristics cannot be identified, we recommend that all states with fee schedules be grouped together for purposes of determining the credibility complement.

B. Changes to NCCI Procedure (Section 3b)

"Would more accurate trending be likely with a different model or with revisions to the current model?"

1. Evaluation Criteria (Page 48)

In evaluating NCCI's procedure, we primarily reviewed the effect of each aspect of the procedure on projection accuracy. This differs from NCCI analyses in that they base their evaluations on the resulting goodness-of-fit. That is, to the extent that a trend line produces a better fit to the data in the experience period used for trend, it is considered superior by NCCI. It is our opinion that it is more appropriate to measure the effect on projection accuracy, rather than historical goodness-of-fit, because the purpose of trend is to project losses two to three years after the experience period used for trend, not to measure the ability of the trend line to fit the historical experience. If a method fits the historical experience well, it will often

TREND

be a good predictor. There are many situations, however, in which a good fit does not imply high projection accuracy.

2. Data Underlying Calculation (Page 39)

In many lines of casualty insurance, trends are estimated for claim frequency and severity (average claim size), separately, as compared to the analysis of loss ratios performed by NCCI. We have identified advantages and disadvantages of the separate projection of frequency and severity. At present, insufficient historical audited claim counts are available from Financial Calls to make projections of ultimate claim counts and, hence, claim frequencies and severities. We recommend that, when sufficient claim count data are available, NCCI perform tests of the projection accuracy of frequency and severity trends and re-evaluate the choice of data underlying the trend calculations.

3. Statistical Approach (Page 46)

NCCI currently uses a statistical method known as least squares regression to estimate trend. Our tests indicate that projection accuracy may be improved through the use of double exponential smoothing or its equivalent, least squares regression with exponential weights.¹ These techniques rely on weighted averages of the underlying data to estimate trend with more weight given to recent data. As a result, these approaches react more quickly to changes in trend rates.

Our analysis indicates that most methods of projecting trend are reasonably accurate in situations in which the trend rate is relatively stable over time. There are many factors that can change the rate of trend or the level of the losses. Methods that respond quickly to such changes without overreacting to outliers (points far from the trend line) will tend to be better predictors of future loss experience.

Another technique that we found promising for longer term study, particularly for medical, is econometric modeling. While the projection accuracy of the simple models tested was not quite as good as that of exponential smoothing, we believe that, with further study, more complex models can be derived that will improve

1 D. A. D'Esopo, "A Note on Forecasting by the Exponential Smoothing Operator," Operations Research, Vol. 9, (1961), pp. 686-687.

TREND

projection accuracy. One of the key advantages of econometric models is their ability to identify and respond to changes in the level of losses and/or the trend rate.

Our conclusion with regard to the number of years used to estimate the trend rate is that the current NCCI practice of using five years is generally reasonable for the linear model. If, however, the exponential model is used, we recommend that NCCI consider extending the experience period to seven or eight years. We also recommend that NCCI periodically (every three to five years) review the projection accuracy of trends based on experience periods of different lengths. It should be noted that the choice of experience period length has less effect if a weighted least squares approach (with exponential weights) is used.

4. Credibility and the Credibility Complement (Page 56)

NCCI's procedure for determining the credibility of an indicated trend rate in each state is based on "classical" credibility theory. In classical credibility, the credibility of an indication is based on its statistical significance. A flaw in this approach is that it does not take into account the ability of the credibility complement (the alternative estimate to which 100% minus the credibility is applied) to estimate the trend rate for a particular state. That is, regardless of the appropriateness of the credibility complement, classical credibility will give the same credibility to a particular indication.

We concluded that a Bayesian credibility approach is theoretically preferable to the classical approach. The important distinction is that, in a Bayesian approach, credibility is assigned based on the relative predictive value of the state indication and the credibility complement. We recommend that NCCI move toward the adoption of a Bayesian credibility approach unless subsequent investigation reveals an unanticipated problem.

We used two approaches to measuring the relative predictive value of the state indication and the credibility complement. First, we tested several empirical Bayesian credibility techniques analogous to those documented in the actuarial literature. These tests indicated that the predictive value of the credibility complements was relatively poor and, therefore, that the state credibilities assigned by NCCI's formula are too low. Second, we performed direct tests of prediction errors based on the state trend indications as compared to those based on the credibility complements. The tests of prediction errors, limited to an eight-state

TREND

sample, did not support the above indication regarding the poor predictive ability of the credibility complements. However, the tests of prediction errors were far from conclusive due to the limited sample size. In Section V and Appendix B, we describe an approach whereby Bayesian credibilities could be calculated based on a comparison of actual historical prediction errors between state indications and the credibility complements (given adequate data availability).

We recommend that the Bayesian approach based on prediction errors be pursued, as well as additional testing and consideration of other empirical Bayesian credibility techniques, such as those tested in our analysis.

NCCI assigns credibility based on the quality of the line fit in each state. This approach leads to credibilities which are more unstable than more common volume-based credibility measures. We found no evidence supporting the quality of fit approach over more stable measures. We tested two approaches to volume-based credibility and found the approach described herein as "volume plus a constant" to be preferable.

We recommend that credibility be based on a measure of volume, preferably using the "volume plus a constant" approach. This change could be implemented as part of a Bayesian credibility procedure or as part of a classical credibility framework if, after investigation, NCCI does not implement a Bayesian credibility procedure.

C. Economic and Benefit Changes (Section 3c)

"Are adequate adjustments made to projections by the NCCI's trend model when significant legal or economic changes occur on a state or national level?"

As noted above, many factors can influence the level of losses and the trend rate. High on the list of such factors are economic changes, such as recessions or shifts in the key industries in a region, and benefit changes, such as the introduction of medical fee schedules and changes in compensation formulas. Our analyses included a review of the procedures used by NCCI to evaluate the impact of such changes on the trend procedure.

TREND

1. Economic Changes (Page 75)

It is our understanding that NCCI has not made adjustments to the trend procedure to address economic changes in specific states or regions. This is not unusual in actuarial analyses. Not only is the impact of economic changes on trend difficult to measure, but the timing and magnitude of the changes themselves are not subject to precise measurement or prediction. Until further research by actuaries and econometricians improves the prediction of economic changes and their impact on trend, it is unlikely that accurate prospective adjustments can be made. The most promising approach for performing such research is through econometric analysis. We recommend that NCCI perform extensive analysis of econometric models. Such models can be valuable not only in states with significant economic changes, but have the potential to improve projection accuracy in more stable situations as well.

Economic changes that occurred during the experience period used to derive the trend rate should be carefully evaluated. For example, a trend rate based on a period of economic recession would not necessarily be appropriate for a period of recovery. Review of long-term trends and econometric analysis can provide guidance regarding adjustments to the trend rate for the impact of such changes during the experience period.

2. Benefit Changes (Page 80)

The impacts of benefit changes on trend are reflected primarily through the adjustment of losses to the current benefit level. For each benefit change, a law amendment factor is calculated to estimate the impact of the benefit change on losses at the time that the change is implemented. These factors are combined to derive factors to adjust losses from the experience period to the current benefit level before the trend estimates are derived.

NCCI has developed a procedure to evaluate the impact of a medical fee schedule on trend, the bent-line procedure. This procedure could be improved through certain refinements. In particular, an assumption implicit in the procedure is that all newly introduced medical fee schedules will be effective (as currently defined by NCCI) in reducing losses and trends. Historically, only about two-thirds of such fee schedules implemented more than five to seven years ago have been effective (as defined by NCCI) in reducing medical trends. Therefore, the NCCI procedure will

TREND

tend, on average, to understate trend in states in which a medical fee schedule has been recently introduced.

In recent years, a few judgmental adjustments have been made by NCCI to the indicated trend rates in states with significant benefit changes. In general, such adjustments are appropriate. We recommend further analysis of historical experience to evaluate which benefit changes have tended to have a predictable impact on trend. Such analyses may prove valuable in estimating the impact of similar changes on the trend indications in other states.

D. Adjustments for Automatic Benefit Changes (Section 3d)

"Contrast the current model, which puts all losses to a current benefit level, to a model which puts all past losses to the same "relative" value of prospective benefits."

As noted above, losses are adjusted to reflect the current benefit level through the use of law amendment factors. These factors are calculated for all benefit changes, including increases in benefits due to automatic increases in minimum and maximum indemnity benefits. The NAIC, in its request for proposal, outlined an alternative approach in which losses are adjusted to the same relative benefit level. As such, the impact of automatic benefit changes would be estimated through the trend rate itself, rather than through specific adjustment factors.

Our conclusion is that the alternative approach is likely to increase projection accuracy to a small degree by removing potential distortions in the loss ratios used in the trend calculation. Also, the alternative approach is strongly preferable for purposes of econometric analysis. We recommend that the alternative approach be adopted at least with regard to benefit changes that occur automatically as a function of the state average weekly wage or a similar index. However, it should be recognized that the impact of this change will be small in most situations and could be in either direction for a particular filing, although increases in indicated rate changes appear likely to be more common than decreases. In addition, work will be required to change the NCCI systems and to educate those involved in the rate filing and review process regarding the change. We do not consider this to be a high priority recommendation to implement (Page 92).

TREND

A method for implementing this alternative approach for other types of benefit changes is provided later in this report. This approach also will eliminate the distortion evaluated in Section 3f. We recommend that NCCI evaluate the practicality of implementing this method for all benefit changes.

E. Distortions in Premium On Level Factors (Section 3e)

"Estimate the likely magnitude of distortions due to changes in the mix of business by class and discuss whether an improved procedure would be warranted."

Changes in the mix of business by classification can cause distortions in premium on level factors. In the limited sample of states that we studied, we found some degree of misestimation of on level premiums. While the trend rates were not significantly distorted, it is possible that they would be in other cases. It would be necessary to use Statistical Plan data to completely avoid the distortion. We recommend that Financial Call data continue to be used for trend calculation, but that Statistical Plan data be used to test for this distortion on a regular basis (Page 98).

For the purposes of calculating premium on level factors for the overall ratemaking procedure, we recommend that the effects of applicable rate changes be re-estimated using the exposure distribution from the year of Statistical Plan data that is closest (or equal) to the experience year.

F. Distortions in Benefit On Level Factors (Section 3f)

"The NCCI brings past losses to a current benefit level by multiplying the various law change factors estimated at about the time the law changes went into effect. Is this an accurate method?"

The NCCI's multiplicative combination of separate estimates of the effects of a series of benefit changes at different times causes a distortion in benefit on level factors. Our analysis indicates that this distortion is likely to cause a downward bias in trend indications. The extent of that bias might be quite small; however, we did not

TREND

estimate the amount of bias in our analysis. We recommend that additional study be performed to estimate the magnitude of the bias (Page 106).

TREND

III. CURRENT NCCI APPROACH

A. Overview

NCCI's approach for estimating trend is a least squares line fit. This technique is also known as linear regression. (The NCCI's Actuarial Committee has recently approved the use of an exponential curve fit as the primary model. A straight line will be used in states in which it is clearly statistically superior.) Indications based on both individual state experience and "countrywide" data (that of groups of states, actually) are derived. These indications are weighted based on the credibility of the trend indication from the state being reviewed.

B. Trend Period

The experience underlying the rate level projections is comprised of the most recent policy year and the most recent calendar-accident year. Generally, 12 to 18 months elapse between the midpoint of the experience period and the date that the rate filing is prepared. Additionally, 15 to 21 months elapse between the time when the calculations are made and the midpoint of the period during which policies written at the projected rate levels will be in effect, known as the Midpoint of the Rate Effective Period. Thus, the experience is commonly trended for 27 to 39 months.

C. Data Underlying Calculation

NCCI uses five policy years of data to determine the trend rate. Trends are calculated using loss ratios adjusted to current rate and benefit levels for indemnity and medical, separately. Premiums and losses adjusted to the current rate and benefit levels are referred to as being "on level." Excerpts from an Arkansas rate filing will be used to illustrate these calculations and are included as our Exhibit 1.

TREND

1. Earned Premium Adjustments

Standard earned premiums are developed to fifth report and adjusted to reflect the current rate level. As shown in Section A of Appendix A-V (our Exhibit 1, Page 8), standard earned premiums [Column (1)] are multiplied by development factors [Column (2)] and on level factors [Column (3)] to derive the Adjusted Standard Earned Premiums in Column (4).

To the extent that the derivation of the rate level adjustment factors is accurate, Adjusted Standard Earned Premiums are proportional to unlimited payroll adjusted to reflect the relative exposure to loss by class. It is therefore essentially a measure of exposure and should not be affected by changes in the adequacy of rate levels.

2. Adjustments to Losses

Losses are developed to ultimate using the same type of data (e.g., paid, incurred including IBNR, or incurred excluding IBNR) as are used to project the policy year losses in the experience period to ultimate. Losses are then adjusted for the effect of any benefit level changes. These calculations are shown in Sections B and C of Appendix A-V of the Arkansas filing (our Exhibit 1, Page 8) for indemnity and medical losses, respectively.

3. Loss Ratios

The loss ratios used in the trend calculation are ratios of developed, on-benefit-level losses to developed, on level earned premiums, as shown for indemnity and medical in Columns (3) through (5) of Sections D and E (see Page 14), respectively. These loss ratios can be thought of as pure premiums derived using Adjusted Standard Earned Premiums as an exposure base.

D. Statistical Approach

Linear regression is then applied to the adjusted loss ratios for the most recent five policy years. In linear regression, a line is estimated so that the sum of the squares of the differences between the fitted line and the actual data is minimized.

Figure 1, on the next page, illustrates this concept. The line shown is the one that minimizes the squares of the distances between the actual points, represented by

TREND

the triangles, and the fitted line. These distances are denoted by the letter "d" in the figure.

The two parameters of the fitted line are often referred to as the location parameter and the slope parameter. In the context of least squares regression, the location parameter is more commonly referred to as the intercept. It is the slope parameter that is of greater interest as it measures the annual change in loss ratios. The formula for the line is:

$$\text{Loss ratio} = \alpha + \beta (\text{time index}) + e,$$

where the time indices correspond to policy years and e is an error term. For the five-year experience period, the time indices are 1 through 5, as shown in Column (2) of Sections D and E. For projection purposes, estimates of α and β ,

TREND

referred to herein as $\hat{\alpha}$ and $\hat{\beta}$, are derived. The projected value of e is set equal to 0 which is its expected value if the linear model is appropriate.

In the linear regression model, the loss ratio for each policy year is assumed to be a single observation from a range of possible results. Several key assumptions underlie the linear regression method:

- (1) The expected value of the error for each policy year is zero;
- (2) The probability distributions of the error terms for each of the policy years have the same variance, independent of the policy year; and
- (3) The errors observed for different policy years are statistically independent.

Furthermore, it is frequently assumed that the error terms are distributed with a Normal distribution. This assumption is used in making confidence interval projections, such as those used in the NCCI credibility procedure.

The formula for $\hat{\beta}$ is:

$$\hat{\beta} = \frac{n \sum_i x_i t_i - \sum_i t_i \sum_i x_i}{n \sum_i t_i^2 - (\sum_i t_i)^2},$$

where $i = 1, \dots, n$, n is 5 (years), the t_i 's are values of the time index and the x_i 's are observed loss ratios.

The Annual Increment in Loss Ratio, Line (9), corresponds to the slope parameter of the linear regression. Column (6) of Sections D and E shows the squares of the time indices and Column (7) shows the products of the time indices and the loss ratios. Table 1, on the next page, shows the terms in the formula in Line (9) that correspond to the formula for $\hat{\beta}$. Also shown are the values for indemnity and medical from the Arkansas filing.

TREND

<u>Line (9) Formula</u>	<u>β Formula</u>	<u>Indemnity</u>	<u>Medical</u>
n Sum (7)	$n \sum x_i t_i$	25.90	21.98
Sum (2) Sum (5)	$\sum t_i \sum x_i$	25.74	21.69
n Sum (6)	$n \sum t_i^2$	275	275
Sum (2) Sum (2)	$(\sum t_i)^2$	225	225

The formula for $\hat{\alpha}$ is:

$$\hat{\alpha} = \frac{\sum_i x_i - \hat{\beta} \sum_i t_i}{n}$$

This is shown in Line (10). The points on the fitted lines for each policy year in the experience period are shown in Column (8).

Underlying linear regression is the assumption that the differences in the trended amount are constant on a year to year basis. By comparison, the assumption underlying exponential regression is one of constant percentage changes. Quantities such as inflation are commonly modeled using exponential models.

E. Trend Factor Based on State Data

Trend factors for each of indemnity loss ratio and medical loss ratio are desired from the midpoint of the experience period to the midpoint of the rate effective period. The time indices for these dates are shown in Lines (11) and (12).

The experience period in this example is comprised of Policy Year 1987, with an exposure period midpoint of January 1, 1988, and Calendar-Accident Year 1988,

TREND

with a midpoint of July 1, 1988, giving an overall midpoint of April 1, 1988. The index for the midpoint of each policy year corresponds to January 1 of the subsequent year. Thus, April 1, 1988 is 0.25 years after the midpoint of Policy Year 1987, giving a time index of 5.25.

The filed rates are assumed to remain in effect for one year. Hence, the midpoint of the rate effective period is assumed to be 12 months after the effective date of the filing. The sample filing for Arkansas was originally filed with a June 1, 1990 effective date. The trend calculation was not revised when the filing was resubmitted. Thus, the midpoint of the rate effective period is assumed to be 12 months after June 1, 1990, that is, June 1, 1991. This midpoint is 38 months or 3.167 years after April 1, 1988, giving a time index of 8.417.

The Trend Factors prior to Credibility represent the trend indications based solely on the state's experience. They are calculated as the fitted loss ratios at the midpoint of the rate effective period ($\hat{\alpha} + 8.417 \hat{\beta}$) divided by the fitted loss ratios at the midpoint of the experience period ($\hat{\alpha} + 5.25 \hat{\beta}$). These ratios are shown in Line (13).

F. Credibility

Credibility is "a measure of the credence that the actuary believes should be attached to a particular body of experience for ratemaking purposes."² To estimate the credibility of the trend estimates for indemnity loss ratio and medical loss ratio in each state, NCCI relies on classical credibility theory. Under this theory, assumptions are made regarding the probability distribution of the estimate. From these assumptions, a full credibility standard is determined. If the full credibility standard is met, 100% credibility is assigned to the estimate. Otherwise, partial credibility is determined using the square root rule.

NCCI has based its full credibility standard on the ratio of the sum of squared residuals calculated from the curve fit to the square of the fitted loss ratio at the

2 L. H. Longley-Cook, An Introduction to Credibility Theory, Casualty Actuarial Society, New York, 1962, p. 3.

TREND

midpoint of the experience period used for trend. The sums of squared residuals are calculated as the sums of the squares of the differences of the values shown in Columns (5) and (8) of Appendix A-V, Sections D and E (See Page 14). These sums are shown in Line (14).

The full credibility standard was selected so that there is 90% confidence that the estimate of the loss ratio at the midpoint of the experience period used for trend will be within $\pm 5\%$ of its theoretical mean, assuming that the error terms are Normally distributed. The value of the full credibility standard is 0.0011. Partial credibility is determined as:

$$\left[\frac{0.0011}{\left(\frac{SSR}{MID^2} \right)} \right]^{\frac{1}{2}}$$

where SSR is the observed sum of squared residuals and MID is the projected loss ratio at the midpoint of the experience period used for trend. The above formula is subject to a maximum of 1.00. The values of MID are calculated as the location parameters [Line (10)] plus 3 times the trend parameters [Line (9)]. The credibility of each trend estimate is shown in Line (15).

G. Annual Expected Trend

To the extent that the indemnity and/or medical trend indications, based on an individual state's experience, are not fully credible, the indicated trends are weighted with the respective annual expected trend (the credibility complements). The annual expected trends are shown in Line (16) of Appendix A-V of the Arkansas filing (See Page 14). These are expressed as annual increases in loss ratios as a percentage of the loss ratio at the midpoint of the experience period used to derive the rate level (e.g. corresponding to the time index in Line (11)). Comparable quantities on a state basis would be calculated as Line (13) minus 1 divided by the trend period [Line (12) minus Line (11)].

The on level, developed premium and loss data underlying the derivation of the annual expected trends are the sums of the data from each of the individual states

TREND

for which NCCI projects rate levels. The loss projections therefore reflect a combination of approaches for developing losses, determined by the methods selected for each state. The annual expected indemnity trend is derived in the same manner as is described above for individual states.

For medical trends, states are separated between those that have "effective" medical fee schedules and those that do not. The medical trend is first determined based on each state's data through the linear regression method discussed previously. The medical trend indications for those states that have medical fee schedules are then reviewed to determine which states have medical trend indications that are higher than the 33rd percentile of the trend indications for states that do not have medical fee schedules. Any state with a fee schedule and a trend indication higher than the 33rd percentile of those with no fee schedule is then combined with the states that do not have a medical fee schedule. The remaining states are deemed to have "effective" medical fee schedules.

The states included in the calculation of the annual expected trend for each of fee and non-fee states as of December 31, 1988 are shown in Table 2, on the next page. Those identified with an asterisk have medical fee schedules that are deemed to be ineffective. All of the states listed are used in the derivation of the indemnity annual expected trend.

The annual expected medical trend for a particular state is the one corresponding to the group in which that state was placed for calculating the annual expected medical trends. As of December 31, 1988, the annual expected medical trends for states with and without effective medical fee schedules were 0.004 and 0.077, respectively. Note that the Arkansas rate filing was initially prepared based on the December 31, 1987 annual expected trends of 0.050 for indemnity and 0.070 for non-fee medical.

H. Credibility-Weighted Trend Factors

The annual expected trends are multiplied by the difference between the midpoints of the rate effective period and the experience period, and 1.00 is added to derive an expected trend factor. The Trend Factors prior to Credibility (based on the state's experience) are then multiplied by their respective credibilities and added to the expected trend factors multiplied by one minus the credibilities to derive the

Credibility-Weighted Trend Factors for indemnity and medical. These calculations are shown in Lines (13) through (17) of Appendix A-V, Sections D and E (see Page 14).

I. Overall Trend Factor

The overall trend factor is calculated as a weighted average of the indemnity and medical trends. The weights used are the developed, on level losses for the most recent policy year. These calculations are shown in Section F on our Exhibit 1, Page 10.

TREND

J. Inclusion of Trend in Rate Level Calculation

In recent NCCI rate filings, two approaches are used to recognize the trend. In some states, the trend for the entire period from the midpoint of the experience period through the midpoint of the rate effective period is recognized in a single trend adjustment. This is illustrated in the Iowa filing excerpt included in Exhibit 2. The indicated overall trend factor of 1.115 derived in Section F of Appendix A-V of that filing (Page 5) is included in Line (2) of Exhibit I-B (Page 1).

In other states, the total trend is separated into two components: the trend in the current rates and the change in trend. The trend in the current rates is defined as the total trend factor that was included in the previous filing for that state. (The only circumstance in which a factor different from the one filed is used is if the regulator specifies a different trend assumption in determining the approved rate change.) To the extent that loss ratios have increased due to trend between the experience period in the prior filing and the current one, it is recognized in the rate filing as a part of the rate change due to a change in experience. The trend factor reflected in the current rates is divided out of the factor used to adjust standard earned premiums to the current premium level. This is shown in Columns (7) and (8) of Section A of Appendix A-III in the attached excerpt from an Arkansas rate filing (our Exhibit 1, Page 7).

The change in trend is calculated as the total trend adjustment divided by the portion reflected in the current rate levels. It is multiplied by the Indicated Premium Level Change from Experience to derive the Indicated Change Modified to Reflect Change in Trend Factor. It represents the change in the rate level due to a change in the trend assumption. This calculation is shown in Exhibit I, Section E (our Exhibit 1, Page 5).

The net effect of both approaches is identical (except for possible rounding differences). In the latter approach, the rate level indication from experience is higher than under the former approach. The rate change from trend is lower by an offsetting amount.

TREND

K. Special Situations

In several states, variations from the trend procedure described above are made. Factors leading to such variations include anticipated changes in trend resulting from benefit changes and direction from regulators. This section describes several of these special procedures.

1. Medical Fee Schedules

Historically, no changes were made in the derivation of the trend indication for a state that has introduced a medical fee schedule during or after the five-year experience period from which trend rates are derived. That is, no adjustment was made in the state's own trend calculation. Unless the state's own medical trend indication is less than the 33rd percentile of states with no fee schedule, the annual expected trend (the credibility complement) is the non-fee schedule trend. If the trend indication is less than the 33rd percentile of states with no fee schedule, the annual expected trend is the fee schedule trend.

Recently, a new procedure was used in a Texas filing which recognizes the potential reduction in medical trend due to the implementation of a medical fee schedule. Exhibit 3 shows an example of NCCI's calculations.

In the new procedure, referred to as the "bent-line" procedure, the medical trend is first calculated as if no medical fee schedule had been introduced. The loss ratio at the midpoint of the rate effective period is then calculated under three scenarios regarding trend after the implementation of the fee schedule: (1) using the medical trend indicated by the Texas data (before credibility) using the procedure described above (C, on Page 2 of Exhibit 3), (2) using the annual expected medical trend for states with effective medical fee schedules (B), and (3) using the annual expected medical trend for states with no medical fee schedule or an ineffective one (D). The ratio of the loss ratio based on the Texas trend (C) to the loss ratio based on the non-fee annual expected trend (D) is then used to adjust the loss ratio based on the fee annual expected trend (B) to derive an adjusted loss ratio, E. In other words, to the extent that a particular state's loss ratio trend is higher or lower than the annual expected trend for states with no medical fee schedule, an adjustment is made to the annual expected medical trend for states with effective medical fee schedules. The medical trend is then derived by dividing the adjusted loss ratio, E, by the

TREND

state's fitted loss ratio for the most recent policy year used in the trend calculation, A. An annual trend is also calculated.

An estimate, F, of the loss ratio at the midpoint of the experience period used for determining the rate level (4/1/89) is made by increasing A for 0.25 years of trend. The medical trend factor for the trend period is then the ratio of E, the projected loss ratio at the midpoint of the rate effective period, to F. This trend is then used in the remainder of the trend calculation which corresponds to Section F of Appendix A-V in the Arkansas filing.

2. State Funds

In states with state funds, the experience of the state fund is either (a) reviewed separately, (b) combined with private insurers experience, or (c) excluded from the analysis, depending on the perceived validity for projection purposes of the data received from the state fund. The treatment of the state funds for the trend calculations are as follows:

- a. Reviewed separately: Idaho, Montana, Oregon and Utah
- b. Combined: Arizona and Oklahoma
- c. Excluded: Colorado

In a similar situation, the experience of the assigned risk plan in Michigan is analyzed separately from the experience of the private companies in that state. In states in which the data are reviewed separately, the trend indications from both sources, state fund and private insurers, are weighted. The weights are determined by the relative premium volume of private insurers and the state fund in the most recent policy year.

3. Credibility of Annual Expected Trend Indication

Several years ago, a situation arose in which the annual expected trend indication for medical was not fully credible. That indication was weighted with the fully-credible indication used in the prior year's rate filings.

TREND

4. States with Downward Trend Indications

When losses have decreased relative to wage levels, a decreasing trend will be indicated. This situation occurred in Maryland for the rate level analysis for rates effective January 1, 1991. In light of the decreasing trend and concerns regarding the impact of a significant law change on 1/1/88, a nonstandard procedure for determining trend was used.

As is discussed in Exhibit 4, six regression analyses were performed: linear, exponential and logarithmic regression on each of four and five policy years of experience. The average of the three credibility-weighted indications based on five-year experience periods was used in the rate level calculation. Page 5 of Exhibit 4 shows each of the trend indications and the selected weighted average.

5. Accident Year Trending

Trend calculations based on calendar-accident year data were recently made in three states: Hawaii, Nebraska and New Mexico. Under this approach, accident year losses are compared to calendar year earned premiums to derive the indicated loss ratios used in the trend calculations. As illustrated in Section A (Page 1) of our Exhibit 5 (Hawaii), no earned premium development factors are needed because, at the end of each year, calendar year earned premiums are at their ultimate level.

6. Variations in Experience Period Used for Trend

In some states, the number of policy years underlying the derivation of the indicated trend is other than five. Exhibit 6 shows an excerpt from a Florida filing in which eight policy years' experience are used. In addition, the standard for full credibility was based on a confidence level of 99% of being within 6% of the expected value. It is our understanding that these modifications were made at the request of the Florida Insurance Department.

7. Judgmental Adjustments to Trend

In recent years, the trend rate for medical and/or indemnity has been adjusted judgmentally in response to significant benefit level changes. Examples include:

- a reduction in indemnity benefits in Maine in 1987, and

TREND

- a change in rehabilitation benefits in Colorado in 1987.

In each of these situations, it was anticipated that the change in benefits would change the shape of the trend line. In Maine, no indemnity trend was used for two years. In Colorado, trends were reduced to reflect anticipated reductions in the utilization of vocational rehabilitation.

TREND

TREND

IV. PREVIOUS APPROACHES USED BY NCCI IN 1980s

A. Overview

During the 1980s, several refinements were made to the calculations underlying the derivation of the overall trend factors used in the NCCI rate analyses. The refinements included:

- separate trends for indemnity and medical,
- a completely new approach for determining credibility, and
- introduction of trends other than 0% as annual expected trends.

B. Data Underlying Analysis

Until mid-1982, the trend calculations were performed on combined indemnity and medical loss ratios. These loss ratios were calculated in a manner similar to the current approach with the exception that indemnity and medical losses were combined for projection purposes.

C. Credibility

Until 1984, NCCI used a non-parametric approach based on the Spearman D Statistic to determine the credibility of the trend indication. Spearman's D Statistic measures whether a trend (other than zero) exists through the observed loss ratios. The Spearman D Statistic is calculated as the sum of the squares of the differences between the time index and the rank of the loss ratio for each policy year. The probability that the D Statistic could be less than the observed value if there were no underlying trend (i.e., 0% per year) is determined from a table. Credibility was then determined as a function of that probability, such that credibility increased as the probability decreased.

TREND

When the current credibility procedure was introduced in 1984, the criterion for full credibility was that there was 90% confidence that the projected loss ratio would be within $\pm 6\%$ of its theoretical mean. Full credibility was given if the ratio of the sum of squared residuals to the square of the projected loss ratio was less than 0.0006. The revision to this procedure was made in late 1988.

D. Annual Expected Trend

No annual expected trend was needed when the Spearman D Statistic was used to determine credibility. The annual expected trend was assumed to be 0%. Overall trend indications were limited to the range from -5% to +25%.

When annual expected trends were introduced, it was believed that there should be no inherent trend in indemnity loss ratios. A review of trends from all NCCI states combined confirmed this hypothesis. A single medical annual expected trend was derived based on the experience from all NCCI states.

Increasing indemnity trends were observed beginning in the mid-1980s on an all-NCCI-states-combined basis. In late 1988, an annual expected trend other than 0% was introduced for indemnity, reflecting these upward trends. When the indemnity annual expected trend was introduced, the annual expected trend selected was less than the indication in order to limit the impacts of the trends from a few states that were perceived to distort the overall annual expected trend indications.

Beginning in early 1989, the data underlying the annual expected trend indications were revised. Until that time, annual expected trend indications were based on all-NCCI-states-combined data developed using the incurred, including IBNR, development approach. It was observed, however, that the resulting loss ratios and trend indication did not balance to the total of the results from each of the individual states. As a result, the loss ratios underlying the calculation of the annual expected trends are now derived based on the sums of the on level premiums and losses used in each state's rate filing which reflect the development approach used for each state.

TREND

Medical annual expected trends are currently determined by the presence or absence of a medical fee schedule in a state and, if a fee schedule has been implemented, the state's trend relative to those observed in states with no fee schedule. This change in the medical trend calculation was made in early 1986. Before that time, a single annual expected medical trend was used.

TREND

V. EVALUATION OF NCCI APPROACH AND RECOMMENDATIONS FOR CHANGE (SECTIONS 3a and 3b)

"Are there any expected biases or errors present in the NCCI's general trending procedures? If so, discuss their impact. Would more accurate trending be likely with a different model or with revisions to the current model?"

This section of our report will present the details of our evaluation of the NCCI procedure for estimating trend and our recommendations regarding improvements to that procedure. The format of this section will follow the preceding section in which each aspect of the NCCI procedure was described. The specific questions identified by the NAIC are addressed in subsequent sections.

A. Trend Period

In the NCCI procedure, the trend period is from the midpoint of the experience period to the midpoint of the rate effective period. Implicit in this aspect of the procedure are the assumptions that policies are written evenly throughout the policy year, and that the average accident date for each policy is six months after its effective date.

Table 3 shows the distribution of premiums written for all NCCI states except those with significant distortions from state funds. As can be seen, there are large variations in the percentage of premiums written between months. If the rate effective period begins on January 1, as do all policy years included in the experience period, then no distortions will occur in the projected loss ratio based on policy year data because the average accident dates are expected to differ from their respective midpoints by the same amount. There will, however, still be a distortion in the loss ratio projection based on accident year data.

**Table 3:
Countrywide**

January	20.3%
February	4.9%
March	6.2%
April	9.4%
May	6.5%
June	7.3%
July	12.1%
August	5.7%
September	6.3%
October	9.5%
November	5.4%
December	6.4%

TREND

Table 4 shows the differences between the lengths of the trend periods used in the NCCI projections and the correct trend periods for rate effective periods beginning in each month. That is, a positive difference indicates that the use of the midpoint of the rate effective period extends the length of the trend period thereby overstating trend. These differences were calculated by assuming that:

- The distribution of monthly premium writings equals the countrywide distribution in Table 3;
- The average policy inception date within each month is the middle of the month;
- Policy terms are twelve months;
- Accident dates are spread evenly over the term of each policy; and
- The experience period is comprised of the most recent policy year and accident year.

Table 4: Differences

(in months)

January	0.3
February	-1.1
March	-0.7
April	-0.4
May	-0.6
June	-0.3
July	-0.2
August	-0.7
September	-0.3
October	-0.1
November	-0.2
December	0.1

At trend rates of less than 7% per annum, the distortion in the projected loss ratio will be less than 1%. In states with state funds (and possibly others), the potential distortions are much larger. Table 5, on the next page, shows the distributions of premiums written by month and the differences between the lengths of the NCCI and correct trend periods for Oregon and Montana, two of the states with the largest potential distortions. In Montana, for example, the error in the projected loss ratio could be as much as 2% if the rate effective period does not begin on January 1.

We recommend that the length of the trend period be determined based on estimated average accident dates, reflecting the distribution of premium writings by month, rather than based on midpoints.

TREND

Table 5: Skewed Distributions

	Oregon		Montana	
	Percent Written	Difference (months)	Percent Written	Difference (months)
January	18.9%	0.4	17.7%	0.3

December	1.8%	-0.4	2.7%	-0.3

B. Data Underlying Calculation

NCCI predicts trends in medical and indemnity loss ratios, separately, based on five policy years of experience. Our evaluation of the underlying data included the review of:

- prediction of frequency and severity rather than loss ratios,
- prediction by injury type,
- use of accident year data rather than policy year data, and
- variations in the number of years in the experience period used to predict trend.

TREND

1. Frequency and Severity

NCCI currently bases trend indications on loss ratios that reflect current rate and benefit levels. An alternative that is common for many casualty lines of insurance is to separately evaluate claim frequency and severity (average claim size) trends. Under such an approach, claim counts and losses are developed to ultimate and losses are adjusted to the current benefit level. Either of on level premiums or payroll can serve as an exposure base for calculating frequencies. In our analyses, on level premiums are used as the base for calculating frequencies based on Financial Call data, whereas payroll is used as the base for Statistical Plan data.

a. Additional Insight

An advantage to this alternate approach is that different models are commonly used for each, linear for frequency and exponential for severity. In addition, different factors influence each of frequency and severity. The impact of external factors, such as economic or benefit changes, can sometimes be more easily evaluated for frequency and severity, separately. Thus, to the extent that additional insight is gained regarding trend rates, projection accuracy could be improved as compared to a projection accuracy of loss ratios.

b. Lack of Historical Financial Call Data

Historically, NCCI did not obtain audited claim count data through the Financial Calls, thereby precluding the use of a frequency/severity approach for estimating trend based on that data. Beginning with the December 31, 1989 Financial Call, the description of the claim count information in the Financial Call was clarified and the claim count fields audited. Thus, only one diagonal of audited claim count data is available, thereby precluding the derivation of reliable claim count development patterns. This will allow for more detailed testing of a frequency/severity approach in the future, after sufficient data are available from which to derive development patterns.

Note that the claim counts included in the Financial Call exclude all medical only claims. To the extent that the percentage of claims that are medical only varies over time, there may be some distortions in the projected

TREND

frequencies and severities. We would not expect these distortions to be significant.

c. Shifts Between Classifications

Shifts in the mix of business between classifications will cause greater distortions in claim frequency and severity projections than loss ratio projections. To the extent that exposures shift to classifications with different frequency rates and/or severities, the projections of frequency and severity trend rates are likely to be distorted. This problem is relatively minor for trend projections based on loss ratios, because loss ratio trends are distorted by shifts between classifications only to the extent that the adequacy of the class rates varies between classes.

d. Statistical Plan Data

An alternative to Financial Call data is to use the claim count and loss data from the Statistical Plan. Claim counts are collected and audited for each injury type separately. A drawback of the Statistical Plan data is its age. Due to the additional detail collected, Statistical Plan data are generally not available until, on average, a year after Financial Call data. Thus, if Statistical Plan data were used, measures of trend would be for a period of time that was an additional year removed from the rate effective period. This could result in increased inaccuracy in the estimates of trended losses.

If analyses of frequency trends were performed using Statistical Plan data, the exposure base could be payroll or on level premiums estimated by extending payroll using current rates. To the extent that exposures shift between classes with different loss expectations, the resulting distortions are likely to be greater if payroll were used as an exposure base as compared to on level premiums.

e. Sources of Distortions

It is generally expected that the number of claims will be closely tied to the number of hours worked. Readily available exposure bases include payroll and on level premium which reflect changes in the number of hours worked,

TREND

as well as changes in average hourly wages. Thus, to the extent that average hourly wages increase frequency will be distorted.

SAWW is often used to measure changes in wage levels. In fact, one approach for removing the distortions mentioned above is to adjust all payroll to a common average weekly wage. SAWW, however, also reflects changes in the length of the average work week. Therefore, frequency based on an adjusted exposure base also would be distorted by changes in the average work week, but not by changes in average hourly wages.

f. Projection Accuracy

We performed an analysis of frequency and severity separately based on the Financial Call data for our sample states. A straight line was found to project frequency more accurately than an exponential curve. Exponential curves were used to project severities. Before performing the regressions, medical severities were indexed using the medical component of the (countrywide) Consumer Price Index (CPI). As shown in Table 6, the prediction errors for the frequency/severity analysis were greater than for the line fit, but less than for exponential regression.

	<u>Indemnity</u>		<u>Medical</u>			
	<u>Average Squared Error</u>	<u>Sample Bias</u>	<u>Average Absolute Error</u>	<u>Average Squared Error</u>	<u>Sample Bias</u>	<u>Average Absolute Error</u>
Loss Ratio Models						
Linear	0.007	0.027	0.064	0.003	0.000	0.034
Exponential	0.018	0.059	0.088	0.014	0.037	0.064
Frequency/Severity Model	0.011	0.038	0.067	0.003	0.007	0.039

TREND

g. Recommendation

We recommend that trend continue to be calculated using on level loss ratios until sufficient claim count data are available to perform tests of projection accuracy of trend estimates based on the separate analyses of frequency and severity. To the extent that changes in trend are observed, separate analyses of frequency and severity trends may identify specific factors leading to such distortions. This type of analysis can assist NCCI in evaluating such factors and mitigating their impact on projected trends.

2. Trends by Injury Type

The trend rates derived by NCCI are for all indemnity losses combined and, separately, all medical losses combined. An alternative is to separate losses by injury type, e.g. fatal, permanent total, etc., or between serious and non-serious claims.

a. Additional Insight

As for separate analyses of the frequency and severity of claims, an advantage of projecting losses by injury type is the increased understanding gained regarding the factors contributing to the trend indication. A shift from non-serious (minor permanent partial and temporary total) to serious (fatal, permanent total and major permanent partial) indemnity claims has been observed in recent years. Note that the delineation between major and minor permanent partial claims is based on a "critical value" that, until 1985, did not keep up with claim cost inflation. This would be expected to explain some or all of the observed shift in claims as an increasing percentage of claims exceeded the critical value.

This shift is illustrated in Table 7, on the next page, using the actual frequency of indemnity claims in Florida, as an example. Similar distributions are shown on Exhibit 7 for three additional states. Relative claim frequencies for these four states by injury type are included in the separate Technical Supplement to this report. Even if the average costs of serious and non-serious benefits are constant, a shift in frequency from non-serious claims to serious claims will produce a positive trend rate. This is illustrated in Table 8, on the next page, using the relative claim frequencies in Table 7 for Florida, as an example.

TREND

In Table 8, average claim costs, total claim frequency and on level premiums are held constant. The only quantity that varies is the distribution of claims between serious and non-serious. If there were no such shift, no trend would be observed because the losses in each year would also be constant. Instead, an 11% annual trend is observed in the loss ratios, due solely to the shift from non-serious claims to serious claims. (Similar analyses in the three other sample states - Louisiana, Illinois, and Michigan - produce much less dramatic results, ranging from -1% to 4% annual trends). While this analysis is valuable in understanding the magnitude of the indicated trends, it is not necessarily expected to improve projection accuracy.

Table 7: Florida Frequency Distribution

<u>Policy Year</u>	<u>Serious</u>	<u>Non-Serious</u>
12/80-11/81	8.4%	91.6%
12/81-11/82	9.1%	90.9%
10/82-9/83	9.9%	90.1%
10/83-9/84	11.3%	88.7%
10/84-9/85	12.6%	87.4%
10/85-9/86	15.3%	84.7%
10/86-9/87	18.3%	81.7%

Table 8: Impact of Frequency Shift

Year	(1) <u>Total Claims</u>	(2) <u>Percent Serious</u>	(3) <u>Serious Average</u>	(4) <u>Non-Serious Average</u>	(5) <u>Losses (000s)</u>	(6) <u>On-Level Premium (000s)</u>	(7) <u>Loss Ratio (5)/(6)</u>
1	30,000	8.4%	\$80,000	\$2,000	\$256,560	\$500,000	0.513
2	30,000	9.1%	80,000	2,000	272,940	500,000	0.546

Note: (5) = (1)x[(2)x(3)+[1-(2)]x(4)]/1,000

TREND

b. Age of Statistical Plan Data

A key drawback of analyses of losses by injury type is that these data can only be obtained from the Statistical Plan. Thus, if trends by injury type were to be used, the data underlying the trend calculations would be about one year older, on average. On level premiums could be estimated from the payroll data collected for the Statistical Plan. An alternative is to base loss ratio trends on those observed in pure premiums (losses divided by payroll), but these could be distorted by shifts of business among classes.

c. Projection Accuracy

Another consideration is the potential for increased accuracy if projections were made by injury type. While we did not perform any explicit tests of the accuracy of such projections, a few observations can be made. First, we observed that medical severity trends for different injury types are generally correlated with one another, for a given state. Therefore, to the extent that frequency shifts between injury types are continuous and relatively stable, estimates of medical trends by injury type are not be expected to provide additional accuracy.

Second, with the allocation of claims to injury type, the volume of losses underlying each trend calculation would be reduced. This generally leads to projections that are more volatile. In fact, an analysis of indemnity severities adjusted to the current SAWW indicates that no conclusions could be drawn regarding trends in fatal and permanent total losses in some of our sample states. The data for these injury types were too volatile when analyzed separately to identify an underlying trend line from the random noise. Our sample states were relatively large, so this problem would be more significant in smaller states.

Third, projections of an additional variable, the distribution of claims by injury type, are needed as compared to an analysis of all injury types combined. This could be addressed either through projections of the future distribution itself and the overall frequency or by independently projecting the frequency of claims for each injury type.

TREND

d. Recommendation

We recommend that trends continue to be determined for all injury types combined. The increased volatility and necessity of using the older Statistical Plan data outweigh the potential distortions from shifts in frequency by injury type. If questions arise regarding the magnitude of the indicated indemnity or medical trend or a shift in loss ratios, a review of pure premiums by injury type may provide additional insight. This insight, however, is not generally needed for making routine estimates of trend.

3. Accident Year vs. Policy Year

The current NCCI approach uses premium and loss data sorted by policy year to determine the projected trends for indemnity and medical loss ratios. An alternative is to rely on calendar-accident year data. Under such an approach, premiums earned during a calendar year and losses on claims occurring during a year (accident year losses) are used to determine the loss ratios underlying the trend calculation.

a. Timeliness

The primary advantage of calendar-accident year data is its timeliness. The average accident date for the latest accident year is about six months more recent than that for the latest completed policy year. Thus, accident year data has the advantage that the latest accident year is more current than the latest policy year and will therefore reflect more recent trends. It has, however, the disadvantage of greater uncertainty in the projected ultimate losses.

b. Premium Development

Another advantage of calendar-accident year data is that earned premiums do not need to be developed. Once the calendar year has been completed and Financial Call data tabulated, earned premiums are at their ultimate calendar-year value. Policy year earned premiums, on the other hand, will develop as the result of retrospective premium adjustments and premium audits.

TREND

c. Mismatch of Premiums and Losses

A drawback of calendar year earned premiums is that they do not correspond directly to the loss experience used to determine loss ratios. For other lines of property-casualty insurance, calendar year earned premiums generally more accurately reflect of the exposure during the year. For workers compensation insurance, however, calendar year earned premiums are based on an estimate of the exposure during the year plus adjustments for any errors in the estimates of exposure made in prior years. To the extent that there are differences in the accuracy of these estimates and growth or declines in the volume of premiums, calendar year earned premiums will be distorted. This mismatch does not exist for policy year data.

An alternative method of calculating calendar year earned premiums which NCCI could use to reduce the mismatch with accident year losses was discussed in our report on the NCCI's premium and loss development procedures. In the alternative approach, the premiums from the two policy years contributing to a given calendar year are developed to ultimate. Based on distributions of premium writings by month, the portion of each policy year's exposure that contributes to the accident year's losses is derived. Those portions of each policy year's premiums are then added to approximate calendar year earned premiums.

d. Recommendation

We recommend that NCCI continue to use policy year data in the trend procedure. The benefits of using accident year data that are, on average, six months more recent, are outweighed by the mismatch of premiums and losses and the greater uncertainty regarding the projected ultimate losses for the latest accident year.

4. Number of Years

As for the organization of the data between policy and calendar-accident years, the selection of the number of years of experience to be used in estimating trend is a balance between stability and responsiveness. As the experience period is lengthened, the indicated trend will be less responsive to changes in the trend rate, but will also be more resistant to distortions caused by isolated outliers.

TREND

a. Statistical Accuracy

The variability around the estimator of trend decreases significantly as the number of points in the experience period increases. This can be illustrated, for least squares regression, by reviewing a t-table. To test the statistical significance of a trend estimate, the absolute value of the ratio of the estimate to its standard deviation is often compared to a t-table. If this ratio exceeds the t-value at a given probability level, say α , it is significant

at the $1-\alpha$ level (i.e., if there were no underlying trend, there would be at least $1-\alpha$ probability that the observed trend would be lower than that actually observed). Table 9 shows the t-values at a 90% confidence level. The fact that these values decrease as the number of points in the experience period increases indicates that, given the same relative variation of the points around the fitted line, a trend coefficient of a given magnitude has a greater statistical significance as the number of points in the regression increases. The range around the observed trend estimate in which the true underlying trend rate falls narrows as the number of points increases. To the extent that the trend rate is constant throughout the trend period, more points will improve statistical projection accuracy.

Table 9: t-table ($\alpha = 10\%$)

Number of <u>Points</u>	<u>t-value</u>
3	3.078
4	1.886
5	1.638
6	1.533
7	1.476
8	1.440

b. NCCI Analysis

NCCI performed tests comparing the results of regressions with experience periods of 5 years and 8 years in both 1982 and 1990. The indicated trends were lower using the longer experience period in both sets of tests, reflecting the slower reaction of the analysis performed using the eight-year period to changes in trend rates. The increased responsiveness of the indications from the analysis performed using the five-year period does not necessarily improve projection accuracy. A comparison of the credibilities (based on the sum of squared residuals) of the indicated trends produced mixed results. That is, in the 1982 tests, credibilities were higher when the eight-year experience period was used, whereas, in the 1990 tests, the credibilities were

TREND

generally lower when the eight-year experience period was used. Exhibits 8 and 9 are excerpts from the Minutes and Agendas of the NCCI Actuarial Committee Meetings related to these tests.

c. Projection Accuracy

We performed tests of the projection accuracy of using each of 3, 4, 5, 6, 7, and 8 years of Financial Call data from three of our sample states: Connecticut, Louisiana and Wisconsin. These tests were performed using the experience periods ending with each of Policy Years 1981 through 1986 to project the loss ratios for the policy years two and three years later. As for the tests described below regarding the statistical approach, we included neither the loss ratio for the most recent calendar-accident year nor the effect of the credibility procedure (i.e., the tests focused on the ability to project a future policy year's loss ratio based on different numbers of past policy years' experience).

The analysis of the exponential model indicated that, for medical, the projection errors, measured in points of loss ratio, decreased as the number of years increased, as shown in Table 10. A similar pattern of results was

Table 10: Prediction Errors - Exponential Model

Number of Years	Medical			Indemnity		
	Average Squared Error	Sample Bias	Average Absolute Error	Average Squared Error	Sample Bias	Average Absolute Error
3	0.008	0.024	0.044	0.042	0.037	0.122
4	0.006	0.024	0.043	0.037	0.032	0.123
5	0.005	0.023	0.042	0.030	0.022	0.113
6	0.005	0.018	0.040	0.023	0.008	0.101
7	0.004	0.013	0.037	0.019	-0.004	0.093
8	0.003	0.008	0.033	0.017	-0.014	0.086

TREND

observed for indemnity. The tests showed that the absolute values of the sample biases were minimized using seven years for indemnity and eight years for medical.

The results for the linear model are shown in Table 11. For the linear model, the tests indicated that, as the number of years decreased, so did the sample bias (on an absolute basis). For medical, the average squared and absolute deviations were relatively constant, where as for indemnity, they decreased as the number of points increased.

d. Recommendation

In light of the results of our analysis, the current five-year period appears reasonable for the linear model. If the exponential model is used, we recommend that NCCI consider lengthening the experience period used for trend to include seven or eight years. We also recommend that NCCI periodically (every 3 to 5 years) review the projection accuracy of experience periods of different lengths.

Number of Years	Medical			Indemnity		
	Average Squared Error	Sample Bias	Average Absolute Error	Average Squared Error	Sample Bias	Average Absolute Error
3	0.002	-0.004	0.026	0.018	-0.001	0.093
4	0.002	-0.007	0.026	0.016	-0.005	0.091
5	0.002	-0.011	0.025	0.014	-0.012	0.083
6	0.002	-0.016	0.025	0.013	-0.021	0.076
7	0.002	-0.020	0.024	0.012	-0.029	0.073
8	0.002	-0.024	0.026	0.012	-0.035	0.070

TREND

NCCI will encounter situations in which trend indications from experience periods of different length will vary significantly. In these circumstances, we recommend NCCI review the underlying experience, as well as external factors, such as economic climate and benefit changes, to try to identify the factors leading to the different estimates. It is appropriate for NCCI to judgmentally lengthen or shorten the experience period to reflect any distortions or changes in the underlying experience and/or external factors.

C. Statistical Approach

We evaluated the statistical approach used by NCCI (i.e., use of linear least squares regression) and their planned future approach (exponential regression) by studying the ability of each approach to estimate loss ratios during the rate effective period. For each of the eight sample states, we received eight policy years of Financial Call data. In addition, for three of the eight states, we received an additional seven policy years of Financial Call data. Using the eight policy years of experience, we were able to perform the trend calculations for two experience periods (Policy Years 1981 through 1985 and Policy Years 1982 through 1986) to project the loss ratios two and three policy years later (Policy Years 1987 and 1988) for all eight states. We tested the sensitivity of the results to the time period underlying the trend estimate by using older experience periods for three of our sample states.

The premium and loss data underlying our analysis were adjusted for anticipated development and changes in rate/benefit levels. All of the data for policy years 1979 and subsequent were evaluated as of December 31, 1989. Data for prior policy years were evaluated as of eighth report. We relied on the development and on level factors provided by NCCI. The raw data, development and on level factors, and loss ratios used in our analysis are included in the Technical Supplement to this report.

These projections were used to evaluate the projection accuracy of the statistical methods during the rate effective period. These projections differ from those used in the NCCI rate calculations in two aspects:

- (1) The most recent calendar/accident year loss ratio was omitted; and

TREND

- (2) The indication was derived solely from each state's own data.

The purpose of the former difference was to simplify the calculations, whereas the latter simplification was made to isolate the projection accuracy of the statistical method from that of the overall trend procedure.

It is important to understand in evaluating the results contained herein that our objective was to evaluate the NCCI trend procedure in and of itself. That is, we have assumed that the estimates of ultimate, on level loss ratios are unbiased and that the purpose of the trend procedure does not encompass correction for any biases or variability inherent in the development and on level procedures.

1. Evaluation Criteria

To measure projection accuracy, we reviewed the average deviation (sample bias), average absolute deviation, and average squared deviation of each of the fits performed. These deviations were calculated for forecasts that were two and three years after the end of the experience period used for trend. This represents the general range of prediction periods used in most of the NCCI trend calculations.

R^2 is commonly used to measure the quality of a projection method. It does not, however, measure the ability of a method to make accurate forecasts. Rather, it measures the ability of the independent variable to explain variations in the dependent variable during the historical experience period. Because past correlation does not necessarily imply causation or future correlation, a high R^2 does not necessarily imply good projection accuracy.

2. Linear versus Exponential Trending

a. A Priori Expectations

In most property-casualty lines of business, trend is related, at least in part, to inflation in claim costs. Therefore, exponential curves which represent constant rates of inflation are commonly used to model trend in insurance losses. This suggests a small downward bias in the linear model for medical loss ratios from a theoretical perspective. However, actual loss ratio trends

TREND

are influenced by many factors over any given time period for a given set of states.

This type of trend can be expected to hold for workers compensation medical loss ratios because a major component of medical trend is the excess of medical inflation over wage inflation. On the other hand, the inflationary component of indemnity losses is reflected in the exposure base (on level premium). There is therefore less reason to expect indemnity losses to follow an exponential trend. We, therefore, have no a priori expectations regarding bias in either the linear or exponential model. It is important to recognize the inherent differences in the factors contributing to indemnity and medical loss ratio trend in evaluating all aspects of the trend procedure, not just the selection of a linear versus exponential model.

b. Projection Accuracy

Two sets of tests of projection accuracy were performed: one using all NCCI states, excluding Georgia for which ex-IBNR development data are not available, and one using a sample of three states. The first set of tests were performed by NCCI and were reviewed by M&R. The data underlying these tests included Policy Years 1981 through 1988 evaluated as of December 31, 1990. These tests focused on projection accuracy of the linear and exponential models under recent economic conditions. The latter tests were based on data for Policy Years 1975 through 1988 evaluated as of December 31, 1989. The purpose of these tests was to evaluate the projection accuracy of these models under a wider variety of economic conditions.

Several sets of sample statistics were calculated to summarize the results of the tests for the all-state sample. These included arithmetic averages, as well as averages weighted using Policy Year 1988 on-level premiums as weights. For a sample of this size, we believe that it is appropriate to review the sample statistics calculated using both arithmetic and weighted averages. These statistics are displayed in Table 12, on the next page.

Our interpretation of the results in Table 12, is that, for the time period included in this first set of tests (i.e., using Policy Years 1981 through 1986 to project Policy Years 1987 and 1988):

TREND

Table 12: Summary of Accuracy - Regression Methods

	<u>Indemnity</u>		<u>Medical</u>	
	<u>Exponential</u>	<u>Linear</u>	<u>Exponential</u>	<u>Linear</u>
Arithmetic Averages				
Sample Bias	0.012	-0.008	-0.007	-0.026
Average Squared Error	0.008	0.005	0.005	0.004
Average Absolute Error	0.057	0.051	0.047	0.045
Premium-Weighted Averages				
Sample Bias	-0.001	-0.025	-0.018	-0.039
Average Squared Error	0.005	0.005	0.004	0.004
Average Absolute Error	0.049	0.054	0.044	0.050

Notes:

1. Sample bias is calculated as predicted minus actual.
2. The premiums used in calculating the weighted averages are shown on Exhibit 10, Sheet 1.

- For medical losses, the exponential model performed significantly better than the linear model. The exponential model was more accurate in terms of sample bias and the two models were about equally accurate in terms of average squared error and average absolute error.
- For indemnity losses, the results were inconclusive, but tended to favor the exponential model when premium-weighted averages were used.

It is interesting to note that when arithmetic averages of the squared errors and absolute errors were used, the exponential model's results were not as good, relative to the linear model's results, as when weighted averages were used. This indicates that the exponential model tended to err by a greater amount in states with small volume, as compared to the linear model.

TREND

The sample bias and errors for each model varied significantly among the states, as shown on Exhibit 10. As can be seen on that exhibit, the absolute value of the sample bias from the exponential model was less than that from the linear model in 22 out of 39 data sets for indemnity and 29 for medical. Similar variations in the average squared and average absolute errors can also be observed. Figure 2 shows two pie charts which illustrate, for indemnity and medical separately, the percentages of projections for which:

- both models overestimated,
- both models underestimated, and
- exponential overestimated and linear underestimated.

TREND

We also compared the projection accuracy of linear and exponential regressions using data from three states for nine sets of five consecutive policy years to determine the sensitivity of the above conclusion to the particular time period underlying our analysis. These measures of projection accuracy are shown in Table 13. The measures for each state from these tests are shown on Exhibit 11. In that comparison, the average squared error and average absolute error were lower for the linear regression than for the exponential, but the absolute value of the sample bias was smaller for exponential regression. The results are less conclusive than those found for medical using the more recent time period for all states.

Table 13: Summary of Accuracy - Regression Methods

	<u>Indemnity</u>		<u>Medical</u>	
	<u>Exponential</u>	<u>Linear</u>	<u>Exponential</u>	<u>Linear</u>
Sample Bias	0.003	-0.019	0.007	-0.016
Squared Error	0.022	0.011	0.004	0.002
Sample Absolute Error	0.095	0.076	0.036	0.026

Notes:

1. Sample Bias is calculated as predicted minus actual.
2. Three-state sample.

c. **Inherent Properties**

As noted above, an exponential curve will usually indicate higher projections for points outside of the experience period used for trend if the underlying data are generally increasing. While exponential projections will eventually exceed linear projections in other situations, this may not occur until some time after the rate projection period. The projected curve will dip below the fitted line during the experience period, as illustrated in Figure 3, on the next page. As a result, in the NCCI trend application, trend will often be higher if

TREND

Figure 3: Exponential versus Linear

Note: Experience period is comprised of Time Periods 1 through 5.

an exponential curve is used. In our tests, the exponential projections were higher than the linear projections in most cases and were never lower by more than an insignificant amount. It should be understood that the higher indications produced by exponential curve fits are not to be considered an indication of increased or reduced projection accuracy of such fits, but rather a reflection of the nature of the assumed underlying trend.

d. Recommendations

The tests reflecting the recent economic environment (i.e., using Policy Years 1981 through 1986 to project Policy Years 1987 and 1988) indicated that for medical losses the exponential model was more accurate than the linear model. For indemnity losses, the results were inconclusive, but tended to favor the exponential model when premium-weighted averages were used. Our limited tests using different time periods, reflecting a range of economic conditions, were inconclusive for both indemnity and medical. We believe

TREND

that it is important that, before a model is adopted for long-term use, it be shown to perform better under a range of conditions, not only those that have existed recently. We therefore recommend that NCCI perform tests similar to those contained herein periodically (every two years) which will reflect the then most recent economic environment. We also recommend that NCCI perform a test of projection accuracy over a longer time frame (i.e., five policy years of data predicting two and three years ahead, but differing five-year periods).

3. Alternate Methods

We studied several alternative methods to exponential and linear regression. These methods are:

- weighted least squares regression,
- non-parametric curve fitting,
- minimum absolute deviation trend line,
- least trimmed squares line fitting,
- exponential smoothing, and
- econometric modelling.

Each of these methods is described in detail in Appendix A.

We performed similar tests of these methods as were done for the NCCI approach on the experience in the sample states. Our analyses indicate that some reduction in the sample bias and the average squared deviation may be possible through the use of exponential smoothing methods. In these families of methods, the trend indication is derived using a weighted average of the loss ratios in which the more recent years are given higher weight.

A few of the exponential smoothing methods resulted in slightly lower errors because of their ability to react to changes in the trend rate during the experience period. Table 14, on the next page, shows a comparison of the prediction errors for

TREND

Table 14: Comparison of Prediction Errors

	<u>Stable States</u>		<u>Erratic States</u>	
	<u>Average Squared Error</u>	<u>Sample Bias</u>	<u>Average Squared Error</u>	<u>Sample Bias</u>
Medical				
Best Exponential Smoothing Method	0.0001	-0.006	0.004	0.004
Linear Regression	0.0001	-0.007	0.005	0.006
Exponential Regression	0.0001	0.003	0.024	0.064
Indemnity				
Best Exponential Smoothing Method	0.003	-0.017	0.008	0.029
Linear Regression	0.003	-0.021	0.011	0.066
Exponential Regression	0.002	-0.010	0.031	0.114

the best overall exponential smoothing method (linear fit) and the regression methods (exponential curve) in the states that appear to have a stable trend during the entire experience period, as well as those in states that have less stable experience. As can be seen, the projection accuracy of the methods is generally the same in the stable states. The most improvement in projection accuracy is observed in the states in which the loss ratios and the trend rate vary significantly over time.

As noted in Appendix A, there are some practical drawbacks to exponential smoothing methods. For the exponential smoothing methods, the results are highly dependent upon the initial values of the location and trend parameters and the smoothing constant. (The smoothing constant determines the responsiveness of the results to the most recent experience.) If a large experience period is available, the initial values influence the results to a lesser extent. If a relatively high smoothing constant were used, say more than 0.5, the fifteen years of experience that will eventually be available from Financial Calls will generally be sufficient to overcome concerns regarding the initial values. Statistics texts commonly recommend that the smoothing constant be determined based on trial and error.

TREND

We recommend that NCCI perform further research into exponential smoothing using the loss experience in all states. Our analyses indicate that NCCI's procedure could benefit from revisions to the methodology, particularly with respect to the identification and evaluation of turning points. The methods identified above are often better able to react to changes in trend rates than the current regression technique.

D. Credibility and the Credibility Complement

Credibility procedures involve estimating a quantity by taking a weighted average between an indication based on the most relevant data (the "observation") and an indication based on more stable, but less relevant, data (the "credibility complement"). The weight assigned to the observation is called the "credibility" of that observation (usually denoted by the letter "Z"). In the current NCCI trend procedure, the complement to the trend indication for a particular state is the trend indication for a group of states. Approaches to credibility can be categorized as "classical" or "Bayesian."

1. Classical Credibility

Classical approaches start with a statistical evaluation of the accuracy of the observation, leading to the construction of "confidence intervals" around that observation. A requirement for the widest acceptable confidence interval (e.g. 95% confidence of being within $\pm 5\%$) is selected, somewhat arbitrarily, and denoted the 100% credibility standard. An observation producing a confidence interval smaller than or equal to the 100% standard is deemed 100% credible, while one with a wider confidence interval is assigned partial credibility equal to the ratio of the width of the confidence interval corresponding to the 100% standard to the width of the confidence interval around the observation. More commonly, the 100% standard is translated to a volume requirement (say P_{100}) and partial credibility is assigned based on the volume underlying the observation (say P_{obs}) according to the

formula $\sqrt{\frac{P_{obs}}{P_{100}}}$ (the "square root rule"). Given the common assumption that variance is inversely proportional to volume, and assuming that the observation is

TREND

drawn from a Normal distribution, the two partial credibility approaches are equivalent (see Venter³).

The classical credibility approach is arbitrary and judgmental in a number of respects. While it can be justified by a "limited fluctuation" line of reasoning, it is not in fact the mathematical solution to any well defined problem. Significant drawbacks include:

- (1) the 100% standard is arbitrary, and
- (2) the credibility does not reflect the predictive ability of the credibility complement.

The second drawback is the area of our greatest concern. For example, suppose a state's experience fails to meet the standard and is assigned 50% credibility, but that no appropriate credibility complement is available. It would be preferable in this case to give 100% weight to the state indication, albeit less stable than we would like, rather than give 50% weight to an inappropriate indication. The appropriateness of the complement should be addressed.

2. Bayesian Analysis and Bayesian Credibility

Bayesian analysis starts with a prior ("a priori") hypothesis and an observation. Bayes' theorem is then applied to produce an "a posteriori" hypothesis, the optimal combination of the available information. The a priori hypothesis corresponds to the credibility complement in our case. To apply Bayes' theorem directly, it is necessary to know the form and parameters of the statistical distributions governing both the complement and the observation. These may be postulated but are rarely known in practice.

3 Gary G. Venter, "Classical Partial Credibility with Application to Trend," PCAS LXXIII, 1986, p. 27.

TREND

Bayesian credibility is an approximation of Bayesian analysis developed by Bühlmann⁴. It takes the familiar form of a credibility weighing between the observation and the credibility complement, and it requires estimates of the means and variances, but not the forms, of the distributions. Note that the only additional information required, as compared to classical credibility, is the variance associated with the credibility complement as an estimator of the mean underlying the observation. The weights given to the observation and the complement are then inversely proportional to the variances. Thus, if the variances of the observation and the credibility complement are α^2 and γ^2 , respectively, the weights for the

observation and the credibility complement are $\frac{\gamma^2}{\alpha^2 + \gamma^2}$ and $\frac{\alpha^2}{\alpha^2 + \gamma^2}$, respectively. It has been proven⁵ that the Bayesian credibility solution is identically the Bayesian analysis solution for certain distributions. Bühlmann proved that in all cases, the Bayesian credibility solution is the best linear unbiased estimator for the Bayesian analysis solution.

3. Empirical Bayesian Credibility

Empirical Bayesian credibility refers to techniques where the necessary parameters are estimated directly from the data. While the variance associated with the observation must be estimated for classical credibility as well as Bayesian credibility, the key to Bayesian credibility is the consideration of the variance associated with the credibility complement.

a. The Bühlmann/Straub Model

Bühlmann and Straub⁶ developed techniques for the credibility weighing of individual reinsurance treaty experience against the experience of a

4 H. Bühlmann, "Experience Rating and Credibility," ASTIN Bulletin IV, Part III, 1967, p. 199.

TREND

combined portfolio. Their model is useful whenever the credibility complement is based on combined experience and the details of the individual contributors to the combination are available. It is a natural model to use in developing credibilities for state versus countrywide data.

The variance associated with the credibility complement is estimated by comparing the variance associated with individual state estimates (the "within-state" variance) with the variance among estimates for different states (the "among-states" variance). If there were no real differences among the states, the observed among-states variance would be similar to the average within-state variance. To the extent that the observed among-states variance significantly exceeds the average within-state variance, it provides evidence of real differences among the states. The greater the real differences among the states, the less the predictive value of the credibility complement.

Hachemeister⁷ applied techniques similar to Bühlmann and Straub to trend models (and to linear models in general), considering the specific case of state versus countrywide trend. Meyers⁸ described the techniques applied to classification relativities.

We tested a number of applications of the Bühlmann/Straub Model. Our approaches, discussed in detail in Appendix B, use the Meyers presentation as a starting point. Results of the applications will be discussed in a subsequent section.

TREND

b. The Van Slyke Approach

Van Slyke⁹ presented an empirical Bayesian credibility approach for trend factors in which the credibility complement is no (i.e., 0%) trend. The variance associated with the observation was calculated based on the linear regression model while the variance associated with the (no trend) complement was based on the very simple no-trend model. Since the former model predicts variance increasing with the length of the projection period while the latter model does not, Van Slyke's result is that the trend rate asymptotically approaches no trend as the length of the projection period increases. We consider this result counter-intuitive, a consequence of using inconsistent models to measure the two variances.

c. The Brehm/Guenther Approach

Brehm and Guenther¹⁰ apply the method of mixed estimation to trend credibility. They demonstrate that their approach is equivalent to an empirical Bayesian credibility approach, and cite a state versus countrywide trend example (among others). In the Brehm/Guenther example, the state and countrywide variances are based directly on the variances associated with the state and countrywide trend indications. Under this approach, the countrywide trend will generally be more reliable than that of any single state; accordingly, all states will receive credibilities less than 50%. The distinction in this case is that the Brehm/Guenther measure of countrywide variance relates to the accuracy of the countrywide trend rate as a predictor of countrywide trend rather than its accuracy as a predictor of trend in a particular state.

TREND

d. Using Historical Prediction Errors

Given an adequate data base, it may be possible to derive empirical Bayesian credibilities from direct measurements of the projection accuracy of state versus countrywide experience. In general, the approach is to assemble data for many states over a number of years, and then to compare the accuracy of projections made using only state data with the accuracy of projections using only countrywide data. These measurements of projection accuracy would be used to calculate the state and countrywide variances used in determining the parameters in the Bayesian credibility formulas.

Producing an adequate data base for this type of calculation does not appear to be onerous. As discussed below, eight years of data for all states might be adequate, and a somewhat longer period (say fifteen years) would be ample. With eight years of trend data available, we fit trend lines to five-year periods and measured projection accuracy for projections two and three years beyond the trend data. Thus, for each state we had two readings of the two-year prediction error and one reading of the three-year prediction error. If we had eight years of data for 33 states (the "countrywide" group), we would have 99 readings of prediction errors. Making the data base longer would have advantages of increasing the number of readings and providing measurements over a greater range of economic conditions.

The procedure then involves calculating prediction errors, once with 100% weight to state data and once with 100% weight to countrywide data. Prediction errors would be expressed as percentages of the actual data and mean square errors would be calculated for state and countrywide projections. If α^2 and γ^2 represent mean square errors for state and countrywide projections respectively, then $\frac{\gamma^2}{\alpha^2 + \gamma^2}$ would represent the credibility of the "average" state.

To measure the credibility for individual states, some "base" would be introduced. Measures of volume are commonly used for credibility bases. The current NCCI procedure uses the quality of the fit of the state trend line, and a base of this type could be used as well. Credibility bases are

TREND

discussed further in the next section. The procedure discussed above is presented in greater detail in Appendix B-2.

4. Base for Measuring State Credibility

Whatever credibility method is used, credibility must be assigned according to some "base" which reflects the relative variability of results.

a. Volume

Most commonly, credibility is assigned according to some measure of volume. Five-year state on level premiums provide a readily available, reasonable measure of volume in our case. Five years of claim counts, if available, may make a good alternative measure. For the purposes of this discussion, we will denote the volume measure for state i as P_i (whether or not it represents premiums).

The use of the volume measure is generally predicated on the assumption that volume is inversely proportional to variance. That is, if the variance for state i is α_i^2 , then α_i^2 can be estimated by $\frac{V^2}{P_i}$, where V^2 is a proportionality constant.

Recalling that the Bayesian credibility for state i is $Z_i = \frac{\gamma^2}{\alpha_i^2 + \gamma^2}$, where γ^2 is

the variance of the complement, we can replace α_i^2 by its estimator $\frac{V^2}{P_i}$.

Then, the credibility is:

$$Z_i = \frac{\gamma^2}{\frac{V^2}{P_i} + \gamma^2} = \frac{P_i}{\frac{V^2}{\gamma^2} + P_i} = \frac{P_i}{P_i + K}$$

$$\text{where } K = \frac{V^2}{\gamma^2} .$$

TREND

This is the most common form for Bayesian credibility.

b. Volume Plus a Constant

There may be sources of variance that do not tend to decrease with volume. An example is the possible general failure of the regression model to perfectly model trend. Meyers and Schenker¹¹ suggest the introduction of a constant

term. Thus, the estimator for α_i^2 is now $\frac{V^2}{P_i} + C$. Substituting, the credibility becomes:

$$Z_i = \frac{\gamma^2}{\alpha_i^2 + \gamma^2} = \frac{\gamma^2}{\frac{V^2}{P_i} + C + \gamma^2} = \frac{P_i}{\frac{V^2}{\gamma^2} + \frac{CP_i}{\gamma^2} + P_i} = \frac{P_i}{P_i d + K}$$

$$\text{where } K = \frac{V^2}{\gamma^2} \quad \text{and} \quad d = 1 + \frac{C}{\gamma^2}$$

c. Quality of Line Fit

Under NCCI's current classical credibility approach, credibility is a direct function of the sum of squared residuals ("SSR") of the fitted line (or exponential curve). Volume affects credibility only indirectly to the extent it influences the goodness of the fit.

Directly reflecting the quality of the fit is straightforward in the Bayesian approach. In this case, the variance of the state trend indication, α_i^2 , can be estimated directly as a function of the SSR. Credibility is then calculated according to the basic formula:

11 Glenn Meyers and Nathaniel Schenker, "Parameter Uncertainty in the Collective Risk Model," PCAS LXX, 1983, p. 111.

TREND

$$Z_i = \frac{\gamma^2}{\alpha_i^2 + \gamma^2}$$

5. Results of Testing - Empirical Bayesian Credibility

We performed extensive testing of empirical Bayesian credibility according to the Bühlmann-Straub model. Our applications are discussed in detail in Appendix B. Our tests were based on five years of Financial Call data for thirty-three states. We tested many combinations of data and methods, as follows:

- Loss Types: Indemnity and Medical.
- Data Types: Paid, Incurred, and Incurred excluding IBNR.
- Trend Model: Linear, Exponential, and Adjusted Linear. In Adjusted Linear, all states are adjusted to a common loss ratio level before calculating trends.
- Credibility Formula: Varied according to the three credibility bases previously discussed. We also tested a correction for bias in the credibility estimates.
- State Groupings for Medical: All states combined, fee states vs. non-fee states, "effective" fee states vs. all other.

a. Comparison of Within-State and Among-State Variances

As a general pattern, we found that the variances among the state trend indications were far greater than the variances of the within state trend indications. In other words, the observed variation in trend estimates from state to state is far greater than the random variation which would occur if there were no systematic differences between the states.

Table 15, on page 66, compares the within-state and among-state variances for the various data and method combinations. (Variances for the exponential model, denoted with asterisks, are based on natural logarithms of loss ratios and therefore, differ in scale from the linear variances; however,

TREND

the relationship between among-state and within-state variances is comparable to the linear models).

Note that the among-states variances are many times the within-state variances. Even though the medical fee states are apparently more homogeneous than the other groupings, the analysis indicates that there are significant non-random differences among the states.

b. Comparison with NCCI Credibilities

As a result of the comparison of variances, the credibilities resulting from the empirical Bayesian approach are much higher than those produced by the NCCI formula. Note that the higher Bayesian credibility does not imply that state results are any more reliable than indicated by NCCI's classical credibility approach (in fact, the identical theory has been applied to measure the reliability of state results). Rather, the implication is that the credibility complement is relatively unreliable as an indicator for the trend in any given state.

Table 16, on page 67, compares average credibilities between the volume based Bayesian method and the NCCI method. The Bayesian credibilities based on volume plus a constant or quality of line fit give different estimates for credibilities of individual states, but very similar average credibilities (over all states) to these shown in Table 16 for the volume based method. The Bayesian credibilities are much higher than the NCCI credibilities, even for the relatively more homogeneous medical fee states group.

c. Possible Inaccuracy in Assumptions

Given the dramatic nature of the above results, it is important to examine the assumptions underlying the empirical Bayesian credibility model with a critical eye. In particular, we focus on the "within-state" variance, i.e. the variance associated with estimates of the trend rate in each state.

The variances of the estimates of the trend rate have been derived using standard regression formulas. These variances are valid only to the extent that the trend model itself is valid. In other words, the assumption is that except for random noise, there is a true underlying trend which is constant over time. Given observations of the changing trend rates over long periods

TREND

of time, the imperfection in this assumption is apparent. The implication is that the within-state variances are understated. This in turn leads the estimates of the among-state variances to be overstated, which in turn leads the credibilities to be overstated.

By way of contrast, in most applications of the credibility theory, the quantity being estimated is a mean rather than a trend rate. Unlike trend rates, the standard formulas for the variances of sample means are not dependent on any model for their validity. Thus, in estimating a trend rate rather than a mean, we have an a priori expectation that the model will lead to credibilities that are overstated to some degree. The NCCI procedure is based on the same regression assumptions, and therefore will also tend to understate the variance of the state trend indication.

d. Credibility Formulas

Credibility formulas varied according to the three credibility bases tested and whether the adjustment for bias was applied. We were able to apply each of the formulas discussed without practical difficulty.

The "volume plus a constant" credibility base flattened credibilities, i.e. raised credibilities for low credibility states and vice versa. Overall, average credibility was not significantly affected. The constant was generally found to be statistically significant. In the example of linear trend applied to incurred indemnity losses excluding IBNR, the constant accounted for 43% of the average within-state variance with the remaining 57% inversely proportional to volume.

The quality of line fit credibility base produces a different distribution of credibilities by state, again with similar overall average credibility. Since this base is used in the current NCCI credibility procedure, the pattern of credibilities by state more nearly matches the results of the NCCI procedure, although the Bayesian credibilities are significantly higher.

We were concerned that the quality of line fit base is subject to random variation; i.e., give the same underlying variance in loss ratios around their theoretical mean, the quality of line fit will vary from one trial to the next. This variation could be beneficial if a poor quality of fit has value in

TREND

predicting a poor reading of the trend rate; otherwise, a more stable indicator of state credibility is preferable.

We used a Monte Carlo simulation to test the hypothesis that quality of fit helps predict the accuracy of the trend rate, given constant underlying variance in loss ratios. We simulated 300 sets of five years of loss ratios, each assuming the same (linear) underlying trend, plus independent, identically distributed normal errors. We fit a line to each set by ordinary least squares, and calculated the sum of squared residuals (SSR) and the error in the trend rate. We found no significant correlation between the SSR and the squared error in the trend rate (actual correlation coefficient = -4.3%). We concluded that credibility should be based on the best available estimate of the underlying variance and that the quality of fit in a particular case provides no additional explanatory value.

In accordance with the above result, we conclude that credibilities based on volume are preferable to credibilities based on quality of line fit. Furthermore, the significance of the constant in the volume plus a constant credibility base leads us to conclude that the volume plus a constant approach is preferable to credibilities based on volume alone. Thus, we consider the volume plus a constant credibility base to be the most reliable approach.

The adjustment for bias in the credibility estimates (described in greater detail in Appendix B) is straight forward to apply. The adjustment always increases credibilities, but has a minor effect when credibilities are close to one. The adjustment is imperfect, and given the high credibilities indicated in our testing, is probably unnecessary. However, if additional tests of Bayesian credibility methods produce substantially lower credibilities, the bias issue will be more significant and should be explored further.

6. Results of Testing - Historical Prediction Errors

Using the eight years of available data in our eight-state sample, we projected two and three years ahead from the first five years, and two years ahead from the second through sixth years. We expressed each projection error as a fraction of the projected point, and averaged the squared errors across all states and all two-year and three-year projections. We made projections using state data alone,

TREND

countrywide data alone, the NCCI credibility formula, and the Bühlmann-Straub Model (using quality of line fit as the credibility base). The results displayed in Table 17 are based on linear trend applied to ultimate loss ratios projected using incurred losses excluding IBNR.

**Table 17: Average Squared Relative Error
2 and 3 year projections**

	<u>100% State</u>	<u>100% C.W.</u>	<u>NCCI Cred.</u>	<u>Bayesian Cred.</u>
Indemnity	.0169	.0151	.0139	.0147
Medical	.0806	.0059	.0079	.0072

In particular, note that the errors based entirely on countrywide data are smaller than the errors based on statewide data. This contrasts sharply with the implications of our application of the Bühlmann-Straub Model. While we must be wary of results based on small sample sizes, this test supports the hypothesis that the Bühlmann-Straub credibilities are overstated.

7. Recommendations

We recommend that NCCI continue testing in this area. Our recommendation is based on our conviction that the optimal weights for an average of two estimates should be based on the value of each of the two estimates. Bayesian credibility provides the framework for doing so.

Empirical estimates of the variances of the state trend indication and the complement still need to be developed. In our testing, we found that the Bühlmann-Straub Model produced results which are likely biased towards excessive credibility for the states. The method for determining empirical credibilities using historical prediction errors, as outlined in Appendix B, seems promising. We recommend that NCCI assemble the necessary data and continue testing this approach, as well as other approaches aimed at measuring the relative value of state trend versus the countrywide (or other) complement.

We recommend that NCCI assign credibilities to individual states based on volume, preferably using an approach analogous to the "volume plus a constant" credibility base. This recommendation is not directly related to the issue of Bayesian versus

TREND

classical credibility. It could be implemented as part of a Bayesian credibility procedure or as part of a classical credibility framework if, after investigation, NCCI does not implement a Bayesian credibility procedure.

E. Effective versus Ineffective Fee Schedules

As described above, NCCI splits states with medical fee schedules between those that are effective and those that are ineffective based on the trend rate observed in each state relative to the trend rates observed in non-fee states. An alternative is to evaluate the characteristics of each fee schedule prospectively to identify its anticipated effectiveness. The determination of these characteristics can be validated statistically in those states that have had medical fee schedules for several years.

1. Considerations

a. A Posteriori Groupings

It is always possible to create arbitrary subsets of the states that will show less among-states variance than that of the entire group. These groupings and the resultant reduction in variance do not, however, necessarily increase the appropriateness of the credibility complement.

b. Random Fluctuations Expected

As for all trend calculations, random fluctuations in trend indications for fee states are expected. That is, the trend indication for a particular year for a state that has a generally effective fee schedule could exceed the 33rd percentile of the indications for non-fee states solely due to random variability. It would not be appropriate to infer that the fee schedule was necessarily ineffective.

c. Consistency Between Years

The current procedure for allocating states leads to changes in the group of states that are considered to have effective medical fee schedules from year-to-year. In some circumstances, this has led to increased variations in the

TREND

credibility complement for states with effective medical fee schedules. The alternate approach (grouping states according to fee schedule characteristics) will increase the consistency of the groupings over time.

d. Reduced Trend Expected in Fee States

After a medical fee schedule is introduced, unit charges for each procedure remain constant except when a change is made to the schedule itself. When this occurs, a law amendment factor is derived and the increase in costs is reflected in the benefit on level factors. As a result, the trend observed in on level loss ratios is expected to be reduced with the introduction of a medical fee schedule, even if the fee schedule itself is not effective at controlling losses and trend.

2. Recommendation

In light of the above considerations, we recommend that NCCI perform research to attempt to identify those characteristics of medical fee schedules that determine their effectiveness in reducing medical trends and use that information to split states with medical fee schedules on an a priori basis. If such characteristics cannot be identified, we recommend that states with fee schedules be grouped together for the purpose of calculating credibility complements, rather than including those currently deemed to have ineffective fee schedules with states that do not have fee schedules.

F. Application of Indicated Trend to Data

NCCI calculates the trend between the experience period and the rate effective period as the ratio of the loss ratios derived from the curve fits at the midpoints of each of these periods. The projected loss ratio during the rate effective period is then calculated as the selected trend rate times the average of the loss ratios from the most recent calendar-accident year and the most recent policy year. An alternative that is more commonly used in statistics is to project the loss ratio from the trend line itself. That is, the level of the projected loss ratio, as well as the rate of increase, is determined from the trend line.

This is illustrated in Figure 4, on the next page. The observed loss ratios and the fitted trend line are shown. The point labeled A is the loss ratio for the most recent

TREND

policy year. If we ignore the averaging with the most recent calendar-accident year, the loss ratio projected for the rate effective period is represented by B. Under the alternate approach, the loss ratio projected for the rate effective period would be represented by C which is derived by extrapolating the fitted trend line to the midpoint of the rate effective period. Under the current procedure, B is derived as the product of A and the ratio of C to D.

1. Reliance on a Single Point

The projected loss ratio under the NCCI approach will be much more responsive to the last observed loss ratio than it will be under the alternate approach. To the extent that the most recent point is indicative of future losses, the NCCI approach will more accurately project the loss ratio during the rate effective period. That approach, however, also subjects the projected loss ratio to higher random variability. Because the volume of losses and premiums for each policy year are large, the loss ratio for that policy year is generally considered to be credible.

2. Projection Accuracy

We have evaluated this aspect of the trend projection by comparing the accuracy of the loss ratios projected for the rate effective period using both approaches. As for the tests described above, we have ignored the loss ratio from the most recent calendar-accident year in our comparisons. Our analysis indicates that the NCCI approach is more accurate (has lower average deviations) than the alternative approach for projecting indemnity loss ratios, as shown in Table 18, on the next page. This indicates that valuable information is gained regarding the level of future

TREND

	<u>NCCI Approach</u>		<u>Alternative Approach</u>

Medical	0.004	0.007	0.005	0.008

loss ratios from the loss ratio observed in the most recent policy period. For medical, the prediction errors from the two approaches are essentially the same.

3. Recommendation

Based on the tests of projection accuracy, we recommend that NCCI continue with its current approach.

TREND

VI. ECONOMIC AND BENEFIT CHANGES (SECTION 3c)

"Are adequate adjustments made to projections by the NCCI's trend model when significant legal or economic changes occur on a state or national level?"

In this section, we will identify several different types of economic and legal (benefit) changes that may affect workers compensation trend. For each, we will identify the types of adjustments that have been made in the past by NCCI, as well as our evaluation of the reasonableness and adequacy of the adjustments. Suggestions regarding alternate approaches will be made, but full testing of such alternatives is outside of the scope of this assignment.

A. Economic Changes

Changes in the economic environment of a state or region can affect workers compensation costs. Examples of such changes include those affecting a major industry, such as the decline in the oil and gas industry in Texas, Louisiana, and Oklahoma in the early 1980s, and those affecting the types of workers, such as the shift generally observed throughout the U.S from the manufacturing sector to the service sector. The latter type of shift will be discussed in a later section of this report.

1. Considerations

Historically, NCCI has not revised the trend procedure to reflect economic changes. In practice, it is not only difficult to predict the impact of economic changes on workers compensation losses, but also the timing and magnitude of the economic changes themselves. Due to the lag between the experience period and the time when filings are prepared, however, additional information regarding the economic situation in a state is available. For example, an industry could be newly experiencing difficulties or a region could be beginning a recovery that is not reflected in the loss experience. In these situations, an understanding of the impact of economic changes on workers compensation losses would be of value in making more reliable projections of the losses expected during the rate effective period.

TREND

A difficulty in interpreting the impact of economic changes on workers compensation losses arises from three sources: (1) explanations of a similar phenomenon by two contradictory reasons, (2) the difficulty in identifying that "best" data in advance of the analysis, and (3) to a lesser extent, the smoothing effect implicit in policy year data. An example of the first relates to explanations of increases in claim frequency. A case can be made that, as the economy expands, there is a greater number of less experienced workers who will tend to have a higher frequency of injuries. On the other hand, a case can be made that, as the economy is declining and workers are laid off, the number of soft tissue injury claims tends to increase as workers seek an additional source of income. As a result of such contradictory explanations for increases in frequency, it is difficult to predict whether claim costs will increase with a recovery or a decline in the economy.

It is often difficult to know in advance what types of insurance data and economic statistics will be valuable in determining a good econometric model. As such, econometric analysis often involves extensive research, data collection, and analysis in the model identification phase, not all of which will be cost-justified.

The study of historical linkages between economic changes and workers compensation losses can sometimes be obscured by the smoothing effect of policy year data. Economic changes can often be identified with specific periods of time. Many of the linkages between economic changes and claim costs are more closely related to accident date than to policy issuance date. Since two policy years cover each accident date, what might be a fairly obvious change could be obscured by the policy year trend line.

2. Recommendations

We recommend that NCCI undertake a detailed analysis of econometric modeling for projecting future loss ratios. Such modeling may increase the reliability of projections, as well as provide explanations for changes in losses. In particular, econometric modeling can capture the turning points in projected losses.

In addition, we recommend the review of the loss experience in states in which significant economic changes have occurred to identify any consistently measurable changes in losses or trend rates. In particular, to the extent that the trend rate or level of loss ratios has changed at the inception of a period of difficult economic

TREND

times, it would not be unreasonable to assume that the trend rate or level of loss ratios would revert to its historical level, as the economy reverses itself.

This type of measurement can be performed judgmentally or through the use of regression analysis. A review of losses, pure premiums or loss ratios in graphical form can often assist in such analyses. Regression lines can be fit using not only time as an independent variable, but also an index that measures the state of the economy. If the level of loss ratios is believed to have been affected by a recession, the independent variables would be time and the index. If the trend rate is believed to be affected, the independent variables would be time and the product of time and the index. To the extent that an additional variable is added to the trend projection, a longer experience period will be needed to produce reliable indications. In addition, current information regarding the state of the economy, along with forecasts thereof, will be needed to estimate the value of the index during the rate effective period.

B. Introduction of Medical Fee Schedules

The introduction of an effective medical fee schedule is expected to not only reduce medical costs, but also the rate at which they increase. NCCI has recognized this through the use of different credibility complements for states with and without effective medical fee schedules. In addition, the bent-line procedure, recently used in Texas, provides an adjustment for the trend rate in states in which the medical fee schedule was introduced after the experience period used for trending.

The differentiation in credibility complements for states with and without effective medical fee schedules is reasonable, but that the implementation can be improved as described in an earlier section. For states in which a medical fee schedule has been introduced during or after the experience period used for trending, we recommend that additional adjustments be made and that the bent-line procedure be refined further.

1. States in which a Medical Fee Schedule is Introduced After the Experience Period

The bent-line procedure, described earlier, has been introduced for Texas, where a medical fee schedule was introduced after the experience period. The overall

TREND

approach is a reasonable method for adjusting the state's indicated medical trend in light of the change in the benefit structure. At the same time, the state's trend relative to other states is still maintained. This procedure can be used in states in which the medical fee schedule was implemented after the beginning of the experience period used for the overall rate level calculation.

We recommend, however, that the trend for all states with medical fee schedules be used to determine the adjustment, rather than the trend for states with *effective* medical fee schedules. Unless specific components of medical fee schedules are identified that are clear predictors of the effectiveness of the schedule in reducing medical trend, it is not appropriate to recognize the total potential reduction in medical trend from no fee schedule to an effective fee schedule. Note that the trend for all states with a medical fee schedule may not currently be calculated on a regular basis by NCCI.

Exhibit 12 shows a comparison of the calculations under both the NCCI approach and the proposed modification. The difference in the calculations can be seen in

the Countrywide Fee Loss Ratios at 1/92 in which the pure fee trend of 0.044 is used in the M&R column and the Countrywide (effective) Fee Trend of 0.004 is used in the NCCI column. This change is carried through to the calculation of the Texas Fee Loss Ratio at 1/92, resulting in a significantly higher indicated loss ratio. Figure 5 illustrates the different loss ratios and trends graphically.

The calculations shown on Exhibit 12 involve loss ratios for policy years in the experience period, almost all of which occur before the implementation of the medical fee schedule in Texas on September 1, 1988. If the procedure is applied in

TREND

a state in which the medical fee schedule is introduced after the end of the experience period, we recommend that the procedure be refined so that the lower projected trend is used only after the date that the schedule was introduced. Otherwise, the bent-line procedure will understate the total trend between the experience period and the rate effective period.

Medical costs are expected to increase at the existing trend rate until the fee schedule is implemented. Only after implementation is the lower trend rate expected to be observed. The trend factor between the experience period and the rate effective period should therefore be a weighted average of these two trends. The weights would be determined by the relative time periods between the midpoint of the experience period, the effective date of the medical fee schedule, and the midpoint of the rate effective period.

This is illustrated in Figure 6 for a hypothetical state in which the medical fee schedule is assumed to have been introduced on July 1, 1990. The midpoint of the experience period is January 1, 1989 and the midpoint of the rate effective period is January 1, 1992. The calculations underlying these loss ratios are shown on Exhibit 13.

2. States in which a Medical Fee Schedule is Introduced During Experience Period

It is our understanding that no adjustments are made to the medical trend calculation in states in which a medical fee schedule was introduced during the experience period used for determining trend. The result is that, until a medical fee schedule has reduced medical trend to below the 33rd percentile of states without a

TREND

medical fee schedule, the medical losses may be trended at a higher rate than necessary. This is the combined result of relying on trends during a period in which no medical fee schedule was effective and the use of the higher (non-fee state) credibility complement. Note that this higher medical trend from the state's own experience will be tempered over time as the medical fee schedule reduces losses on claims that remain open from policy years during the experience period.

For states in which the medical fee schedule was implemented early in the experience period, such as during the oldest policy year, we recommend decreasing the number of years used to determine the medical trend. This will tend to eliminate potential distortions in the trend calculation due solely to the implementation of the medical fee schedule.

For other states, we recommend increasing the number of years used to determine the medical trend before the introduction of the medical fee schedule and then performing the bent-line procedure to determine the trend rate after the implementation of the fee schedule. The state's base trend would be estimated using only policy years before the introduction of the medical fee schedule. For these states, the adjusted trend is used for the entire trend period, because the medical fee schedule will have been implemented before the midpoint of the experience period used in the rate level calculation.

As two to three years of experience become available under the medical fee schedule, its impact on trend can be tested by reviewing the trends between policy years after the schedule was introduced. To the extent that measurable decreases in trend are observed, the trend factor can be adjusted accordingly. If no measurable decreases in trend are observed, the bent-line procedure can be used until the most or all of the experience period used for trending is after the introduction of the medical fee schedule.

C. Other Significant Benefit Changes

There are other benefit changes that may change the trend rate. In the past, a few adjustments have been made for such changes. For example, in 1987, Colorado eliminated vocational rehabilitation from its benefit structure. It was believed that the growth of the vocational rehabilitation industry may have led to a higher trend

TREND

rate. Judgmental adjustments were made for several years in anticipation of a reversal of such changes.

Also, there was a large reduction in indemnity benefits in Maine in 1987. As in Colorado, it was believed that both the level of losses and the rate at which they trended would be reduced. As a result, no trend was used for indemnity for two years. In our sample states, there were several large benefit changes, including:

- a significant change in permanent partial benefits in Louisiana in 1983 to a wage loss/impairment schedule system,
- an increase in the maximum benefit from 100% to 150% of the SAWW in Connecticut in 1986, and
- a redefinition of losses to include vocational rehabilitation in Oregon in 1986.

Reviews of the ultimate, on level loss ratios in each state do not generally point to any significant changes in trend resulting from these benefit changes with the exception of indemnity loss ratios in Louisiana. Figure 7 shows the on level indemnity loss ratios for Louisiana. Graphs of the loss ratios in each state are shown in Exhibits 14 through 31 for indemnity and medical, separately.

It is difficult to evaluate whether the change in trend in Louisiana resulted from the change in benefits or the change

TREND

in the economy in that region that occurred concurrently. A review of similar graphs for other states in the same region, e.g., Texas and Oklahoma, may provide some insight. The lack of a parallel change in medical loss ratios is an indication that the benefit change may have led to the change in trend. It may, therefore, be appropriate to review indemnity benefit structures and give separate treatment to those states with wage loss systems or, at a minimum, to implement a procedure that could be similar to the bent-line procedure to recognize the impact on trend of changes to a wage loss system.

In general, we recommend a systematic review of on level loss ratios to identify any benefit changes that are consistently related to changes in the observed trend (a bend in the graph).

TREND

VII. ADJUSTMENTS FOR AUTOMATIC BENEFIT CHANGES (SECTION 3d)

"Contrast the current model, which puts all losses to a current benefit level, to a model which puts all past losses to the same "relative" value of prospective benefits. (In other words, if the prospective min/max benefit level and state AWW were \$100/\$300 and \$320, respectively, then no adjustment would be made to past losses if the past values were \$80/\$240 and \$256. This method would apply a steeper trend line to a lower historic loss level.)"

The NAIC requested that we evaluate an alternate approach for adjusting indemnity losses to current benefit levels in the trend calculation. It was suggested that benefits be brought to the same relative benefit level, rather than to a common absolute benefit level. Examples of the types of benefit on level factor calculations that would be affected by such a change include those for minimum and maximum weekly benefits, the percentage compensation rate, and increases in medical fee schedules.

A. Current Approach

Under the current NCCI approach, historical indemnity losses are adjusted to the current benefit level, with the intention that the losses for each year reflect the provisions, e.g., dollar amount of the minimum and maximum benefits, in effect at the time the filing is prepared. These adjustments are made through the on level factors. Each time the SAWW is increased, a law amendment factor is calculated which estimates the increase in benefits paid in a recent twelve-month calendar period to reflect the revised benefits.

B. Alternate Approach

Under the proposed alternative, law amendment factors would be calculated whenever benefits change relative to the SAWW or other changes in benefits unrelated to the SAWW were enacted. That is, historical losses used in the trend

TREND

calculation would reflect constant ratios of limited benefits to unlimited benefits, rather than a constant dollar level of benefits.

This difference can be illustrated graphically for minimum and maximum benefits, as shown in Figures 8 and 9. These figures show the relationship between the SAWW and the minimum and maximum benefits reflected in the losses used for trend under each approach. In Figure 8, the minimum and maximum benefits are represented by horizontal lines, as they are adjusted to a constant dollar amount. In Figure 9, the lines representing the minimum and maximum benefits increase proportionally to SAWW. (For this illustration, minimum benefits of 50% of SAWW and maximum benefits of 150% of SAWW were used.)

A comparison of the calculations of indemnity trend and the resultant indications in two states, Connecticut and Illinois, will be used to illustrate the differences in the approaches. The minimum and maximum benefits in Illinois have remained constant percentages of the SAWW during the entire period used for the trend

TREND

calculation, whereas the maximum benefit in Connecticut increased from 100% to 150% on October 1, 1987.

Exhibits 32 and 33 show the trend calculations for Connecticut and Illinois using the current NCCI procedure. Table 19 shows a comparison of the law amendment factors including and excluding those related solely to increases in minimum and maximum benefits tied to the SAWW. As can be seen, fewer law amendment factors are needed under the alternate procedure. Exhibits 34 and 35 show the trend calculations under the proposed alternative. The trend rate under the alternate approach is somewhat higher than under the NCCI approach. The trend is, however, applied to lower loss ratios resulting from the lower on level factors. It is important to recognize that this change in the trend procedure requires a

TREND

corresponding change in the on level factors used in the overall rate level calculation.

Figure 10 and Figure 11, on the next page, show the resultant fitted trend lines under both approaches.

C. Possible Implementation Procedure

A procedure for implementing the alternate approach has been used internally by one or more state insurance departments. The following steps are performed for each policy period and for the Rate Effective Period.

1. Calculate (or estimate) average values of the minimum benefit, the maximum benefit, the percentage compensation rate, and the average weekly wage.

TREND

2. Based on the values in (1) and the wage distribution table, calculate the average benefit.
3. Divide the average benefit in (2) by the average weekly wage.
4. Benefit on level factors are equal to the value for (3) for the Rate Effective Period divided by the value for (3) for each policy period.

Note that once actual values of the average weekly wage are known, the values in Step (3) above will never need to be recalculated.

D. Considerations

Our discussion of the considerations underlying each approach will focus on indemnity minimum and maximum benefits and changes in the SAWW. These comments also apply to other benefit changes.

TREND

1. Actual versus Estimate

Under the proposed alternative, actual experience regarding the impact of increases in minimum and maximum benefits tied to the SAWW would be included in the trend calculation. This actual experience replaces the law amendment factors which represent theoretical estimates of experience. Accuracy regarding this impact will be increased by the use of the actual experience.

As additional data regarding claim counts become available, a trend procedure that depends upon separate estimates of frequency and severity trend may be considered. If the alternate procedure were also implemented, severity would be expected to be more highly correlated with the SAWW because the limiting effect of the current minimum and maximum benefits on benefits awarded in the past would be eliminated.

2. Understatement of Trend

Under the current NCCI approach, only changes in minimum and maximum benefits tied to the SAWW through the date that the filing is made are included in the on level factors. Any subsequent increases in benefits due to increases in minimum and maximum benefits after the filing is prepared may not be reflected in the rate level calculation. Thus, to the extent that minimum and maximum benefits automatically increase as a result of subsequent increases in the SAWW, the projected rate level will be understated to a small degree by the current approach. Under the proposed procedure, the impact of increases in the minimum and maximum benefits to the midpoint of the rate effective period will be implicitly included in the trend factor, thereby eliminating the understatement of indemnity losses. This can be observed in the graph in Figure 10 comparing the trend lines for Connecticut. The alternate trend line in that graph crosses the NCCI trend line at about the midpoint of the rate effective period.

3. Theoretical Bias

In all actuarial analyses, the existence of a constant dollar minimum or maximum will distort the underlying shape of the trend line. If, for example, it is believed that unlimited losses are trending exponentially at 5% per annum, the observed trend

TREND

will be less than 5% and will decrease over time in the presence of a constant dollar limit on losses. This is illustrated with a simplified example in Table 20.

In that table, 10 claims are shown, each of which is assumed to increase uniformly by 5% per annum. Three averages are calculated: (1) the average of the unlimited claim sizes, (2) the average of the claims limited to a constant dollar amount, and

Table 20: Effect of Limits on Trend

Claim Number	Policy Year						
	1981	1982	1983	1984	1985	1986	1987

		5.0%	5.0%	5.0%	5.0%	5.0%	5.0%

TREND

(3) the averages limited to 150% the unlimited average. Also shown are the indicated trend rates for each of the averages. The trend rates for the unlimited average and the average calculated using an increasing limit are 5%, as expected. The trend rate for the average limited to a constant dollar amount decreases over time. The three averages are shown graphically in Figure 12. The trend lines corresponding to the unlimited average and the average limited to an increasing limit show an exponential shape consistent with the assumption underlying the example, whereas the third trend line is concave downward, reflecting a continuously declining trend rate.

As the trend line continues to flatten using the current NCCI approach, a bias will be created in the trend. The fitted trend line will tend to overstate the true future

TREND

limited trend. This bias of the current approach is in the opposite direction from that discussed in the previous section. Neither of these biases appears likely to be substantial. An additional concern is the difficulty encountered in deriving econometric models using data that has been adjusted using the NCCI approach. To the extent that underlying trends are distorted, it increases the difficulty in identifying relationships between workers compensation losses (loss ratios) and external economic indices.

4. Impact on Law Amendment Factors

If the alternate approach were used, fewer law amendment factors would need to be estimated in states with automatic increases in the minimum and maximum benefits. Only those benefit changes not tied to the SAWW or those affecting the minimum and maximum percentages would need to be evaluated. In many states, this would considerably reduce the number of law amendment factors that need to be calculated. As of early-1990, 72% of states had indemnity benefits tied to the SAWW. In the examples shown above for Connecticut and Illinois, more than 85% of the law amendment factor calculations for indemnity would be eliminated.

Although the number of law amendment factors differs between methods, the difference in their impact is recognized in the trend calculation. Thus, under neither the current nor the proposed approach are benefit changes double-counted as a result of the trend procedure.

5. Automatic Increases Versus Intermittent Increases

The current approach could be continued in those states in which the minimum and maximum benefits do not automatically increase with the SAWW. If the minimum and maximum benefit are stated as dollar amounts and are only changed intermittently, the percentage relationship between the minimum and maximum benefits and the SAWW will vary over time. This necessitates the use of law amendment factors under both approaches. In the alternate approach, indemnity losses in each year would need to be adjusted to common ratios of minimum benefit to SAWW and maximum benefit to SAWW, whereas, in the NCCI approach, indemnity losses would need to be adjusted to reflect the current minimum and maximum benefit. To the extent that the minimum and maximum dollar amounts are not revised annually, the alternate approach would require the calculation of more adjustment factors to adjust losses to common minimum and maximum

TREND

percentages than are currently needed. It is our understanding that these additional calculations are not difficult and do not add significantly to the time needed to prepare a filing.

6. Ease of Explanation

The alternate procedure, in and of itself, is not particularly easier or more difficult to understand. Any new approach, however, may temporarily appear more difficult simply because it is different from expectations.

E. Recommendations

Our conclusion is that the alternative approach is likely to increase projection accuracy to a small degree by removing potential distortions in the loss ratios used in the trend calculation. Also, the alternative approach is strongly preferable for purposes of econometric analysis. We recommend that the alternative approach be adopted at least with regard to benefit changes that occur automatically as a function of the state average weekly wage or a similar index. However, it should be recognized that the impact of this change will be small in most situations and could be in either direction for a particular filing, although increases in indicated rate changes appear likely to be more common than decreases. In addition, work will be required to change the NCCI systems and to educate those involved in the rate filing and review process regarding the change. We do not consider this to be a high priority recommendation to implement.

We have described a method for implementing the alternative approach which could be used for other types of benefit changes as well. We recommend that the practicality of this method (or possibly a different method of implementing the alternative approach) for all benefit changes be evaluated by NCCI.

It should be noted that any changes of this type in the trend calculation should also be made in the calculation of the on level losses used in determining the overall rate change indication.

TREND

VIII. PREMIUM ON LEVEL FACTORS (SECTION 3e)

"The NCCI determines the overall impact of all classification rate changes combined based on the three years of payroll used in the filing at that time. If the mix of business in a state changes over the years, this estimation of the effect of a past rate filing as it would relate to the current mix of classifications may be distorted. Estimate the likely magnitude of these distortions and discuss whether an improved procedure would be warranted."

Premiums used in the trend calculation are first adjusted to current rate levels. When rate changes vary by class, the overall effect of the rate change is a function of the distribution of business among classes. If the class distribution shifts over time, a particular rate change will have different overall effects on different years' premiums. To the extent that inaccurate estimates of overall rate changes are used to bring premiums on level, the trend rate may be distorted.

A. NCCI Approach

Under the NCCI approach, an overall rate change is determined in each rate filing. To the extent that the rate change varies by class, the class rate changes are calculated to balance to the overall rate change. That "balance" is a function of the distribution of payroll by class. NCCI uses the most recent three years of available Statistical Plan data to perform the balancing calculation. Typically, the class distribution used to balance to the overall rate change is from policies written from three to six years prior to the effective date.

NCCI does not use the details of rates or rate changes by class in calculating on level premiums. Rather, on level factors to be applied to total premiums are calculated based on the estimated overall rate changes.

TREND

B. Alternate Approach

Given adequate data, premiums reflecting current rates in combination with exposures for a past year can be calculated directly by multiplying the exposures (i.e. payroll) from the past year times the current rates. This method, called "extension of exposures" or "premiums at present rates" is widely used and is considered superior to the on level factors approach. In particular, a shifting class distribution does not cause a distortion.

For NCCI, only Statistical Plan data has the detailed exposures by class necessary to perform this calculation.

C. Potential Distortion in the NCCI Approach

To describe the potential distortion, we will introduce some notation relating to a single rate change. We will denote the "old" rate (prior to the change) for class i as OR_i and the "new" rate as NR_i . The exposures for class i in year j will be denoted ${}_jE_i$, while the exposures used for "balancing" the rate change will be denoted ${}_kE_i$.

Assuming that the old rates were in effect during year j , the actual manual premiums in year j were $\sum_i {}_jE_i \cdot OR_i$. NCCI procedures use standard premium rather than manual premium. For the purposes of evaluating the effects of shifting classification mix, we have based our calculations on manual premiums.

Since the exposures ${}_kE_i$ were used to balance the rate change, the overall effect of the rate change was calculated as:

$$\frac{\sum_i {}_kE_i \cdot NR_i}{\sum_i {}_kE_i \cdot OR_i}$$

The on level premiums for year j are then the product of the actual manual premiums and the estimated rate change:

TREND

$$\sum_i {}_j E_i \cdot OR_i \cdot \frac{\sum_i {}_k E_i \cdot NR_i}{\sum_i {}_k E_i \cdot OR_i}$$

The more accurate premiums at present rates are calculated directly as $\sum_i {}_j E_i \cdot NR_i$, with the potential distortion caused by the possible differences between ${}_j E_i$ and ${}_k E_i$. In some states, the class distribution has shifted rapidly, so that the potential distortion in on level factors is significant.

Note that ${}_k E_i$ may be older or younger than ${}_j E_i$. The exposures used to balance the rate change average roughly four to five years prior to the effective date, while the years being adjusted precede the effective date by zero to about seven.

The direction of the potential distortion is difficult to predict. Even if the direction of shift in the class distribution is known, the distortion in the estimate of the overall rate change will be a function of the way the rate change varies among classes.

D. Testing

We tested for the distortion using Statistical Plan data from Connecticut, Florida, Illinois, Louisiana, Michigan, Nebraska, North Carolina and Oregon. These include two states (Florida and Louisiana) with dramatic shifts in class distribution. Table 21 displays the percentage change in average class relativity for each test state over a six year period. Specifically the values in the table are average rates using current rates, year 6 distribution, divided by average rates using current rates, year 1 distribution.

Based on the Statistical Plan data we received, we were able to calculate premiums at present rates directly. In addition, we were able to approximate the NCCI on level factor calculations. A detailed description of these calculations is provided in Appendix C.

Table 21: % Change in Average Class Relativities

Connecticut	-2.3%
Florida	-14.5%
Illinois	-4.7%
Louisiana	-16.4%
Michigan	-1.6%
Nebraska	-6.6%
N. Carolina	+0.1%
Oregon	+5.5%

TREND

Table 22 presents, for the State of Florida, the on level premiums calculated with the NCCI approach compared with the more accurate premiums at present rates.

The distortion in fitted annual trend rates for each of the test states is displayed in

**Table 22: Florida
Comparison of Premium Methodologies**

<u>Policy Year</u>	(1) <u>On-level Premiums</u>	(2) <u>Premiums at Present Rates</u>	(3) <u>% Error in (1)</u>
82/83	1,361	1,346	1.2%
83/84	1,551	1,579	(1.8%)
84/85	1,581	1,594	(0.8%)
85/86	1,546	1,562	(1.0%)
86/87	1,550	1,574	(1.5%)

Table 23, on the next page. Note in the case of Florida, a state with a dramatic shift in class distributions, that although the distortion in on level premiums is significant, the resulting distortion in trend factors is small. We generally noted very small distortions in trend, even when large distortions in on level premiums were apparent. We also noted that, in most cases, trend rates were overstated, although by very small amounts.

E. Implications for Overall Ratemaking

Although the focus of this report is trend calculations, the magnitude of possible distortions in on level premiums implies that these issues are important in the determination of the overall indicated rate change.

In the overall ratemaking procedure, earned premiums for the experience period are brought to current rate level based on the estimated overall effects of the applicable rate changes, as calculated at the time those rate changes were implemented. To bring premiums on level accurately, those estimated overall rate changes should reflect the distribution of exposures by class that existed during the experience period. NCCI's method uses older exposure distributions. Our testing as discussed above indicated that the resulting distortion can be significant, especially in a state where the exposure distribution is shifting.

TREND

Table 23: Comparison of Trend Rates

	(1) On-Level Premiums	(2) Premiums at Present Rates		(1) On-Level Premiums	(2) Premiums at Present Rates
Connecticut*			Michigan		
Indemnity	.027	.027	Indemnity	.014	.008
Medical	.013	.013	Medical	.015	.013
Florida			Nebraska*		
Indemnity	.042	.041	Indemnity	.021	.022
Medical	.013	.012	Medical	.017	.017
Illinois			N. Carolina*		
Indemnity	.013	.011	Indemnity	.014	.013
Medical	.009	.009	Medical	.015	.014
Louisiana			Oregon*		
Indemnity	.026	.025	Indemnity	.040	.038
Medical	.029	.028	Medical	.024	.025

* For these states, we could not bring losses on current benefit level. Therefore, the trend rates may be misstated; however, the comparison between trend rates remains valid.

Ideally, the overall effects of the applicable rate changes could be recalculated using the exposure distribution from the experience period. In practice, that exposure distribution is not available, since the exposure distribution is derived from Statistical Plan data, whereas the experience period is based on the latest available Financial Call data. However, if the latest available year of exposures from Statistical Plan data were used to recalculate the overall effects of the rate changes, that would provide a more current exposure distribution than is used in NCCI's procedure. This change would reduce, although not completely eliminate, the possible distortions.

TREND

The procedure for recalculating the effects of prior rate changes is straightforward. For each applicable rate change, average rates before and after the rate change would be calculated as weighted averages of the manual rates by class, using the latest available exposure distribution as weights. The estimated overall effect of each rate change would be the ratio of the average rate after the change to the average rate before the change. On level factors would then be calculated as in the current procedure.

F. Considerations

It is important to consider the likely magnitude of the potential distortions relative to the practicality of correcting them.

1. Likely Magnitude of Distortions

Although we observed some significant distortions in the calculations of on level premiums, they did not generally lead to significant distortions in measured trend rates. Based on our limited sample, we would not, however, conclude that significant distortions in trend rates are not possible.

2. Practicality of Alternate Approach

The alternate approach outlined herein requires Statistical Plan data, which are approximately one year older than Financial Call data. Using older data for the trend calculation would not be desirable, especially considering the minor distortions identified in the sample states.

For the change in the overall ratemaking procedure, implementation would be somewhat easier since fewer rate changes are involved and only one exposure distribution would be used.

G. Recommendations

We recommend that NCCI use Statistical Plan data to test for distortions in trend rates caused by inaccuracy in the on level premiums calculation. If a significant

TREND

distortion is identified in a particular state, an appropriate adjustment to the trend rate should be made.

For the purpose of calculating premium on level factors for the overall ratemaking procedure, we recommend that the effects of applicable rate changes be re-estimated using the exposure distribution from the year of Statistical Plan data that is closest (or equal) to the experience year.

TREND

TREND

IX. BENEFIT ON LEVEL FACTORS (SECTION 3f)

"The NCCI brings past losses to a current benefit level by multiplying the various law change factors estimated at about the time the law changes went into effect. Is this an accurate method?"

Losses used in the trend calculation are first adjusted to current benefit levels. When there have been several intervening benefit changes, the current NCCI procedure estimates their cumulative effect by multiplying the estimates of the effect of each individual benefit change. As an alternative, the combined effect of several benefit changes can be estimated in one step. To the extent that the current procedure produces an inaccurate adjustment to current benefit levels, the trend rate may be distorted.

A. NCCI Approach

Under the NCCI approach, each benefit change is evaluated once, in the rate filing coinciding with the implementation of that change. The estimate of the percentage effect of that change made at that time is used in all subsequent calculations of benefit on level factors.

1. Evaluation of Single Benefit Change

While there are many complex types of benefit changes possible, the most common elements of benefit changes are changes in the minimum and maximum weekly benefits. The percentage rate of compensation may be modified as well.

For benefit changes of these kinds, the central calculation is the determination of the average weekly benefit before and after the change. The result is a function of the distribution of weekly wages among insured workers, as well as of the benefit provisions before and after the change. For the distribution of weekly wages, NCCI uses a standard table expressing that distribution in percentages of the average weekly wage, along with the average weekly wage for the year preceding the change.

TREND

Changes in the average weekly benefits as described above do not generally affect all kinds of claimants to the same degree, with the variations governed by the specifics of state laws. To determine the overall effect of a benefit change, the distribution of different kinds of claimants is used in combination with the degree to which each is affected by the benefit changes. A discussion of NCCI's procedure to evaluate benefit level changes appears in Section IIB - Part 5.

2. Evaluation of Multiple Benefit Changes

The percentage effect of each benefit change is evaluated only once. The effect of multiple changes is then calculated as the product of the individual changes. For example, if the effects of 1987 and 1988 benefit changes have been estimated at +2.4% and +3.6%, respectively, then the combined effect of both changes is estimated to be +6.1% (i.e. $1.024 \times 1.036 = 1.061$). Assuming no other benefit changes, a factor of 1.061 would be used to bring 1986 losses to 1989 benefit levels.

B. Alternate Approach

A more accurate approach to bringing losses for a given year to the current benefit level would be to calculate, in one step, the effect of all subsequent benefit changes applied to the losses for that year. This is different from the current procedure in two important respects:

1. Intermediate benefit levels would not enter the calculation. Only the benefit levels in effect during the year being adjusted and the current benefit levels would be used.
2. The calculation would be based on the wage distribution and distribution of affected claimants that apply to the year being adjusted.

As we will discuss in the next section, the latter difference is more important.

TREND

C. Potential Distortion in the NCCI Approach

Let us consider the central calculation, the determination of the average weekly benefit before and after the benefit changes. For a simple example, we will consider time periods 1, 2, and 3, with benefit changes occurring between Periods 1 and 2 and between Periods 2 and 3. The problem is to adjust losses from Period 1 to the benefit level existing in Period 3.

Introducing some notation, let ${}_xAWB_y$ represent the average weekly benefit based on the wage distribution existing in Period x and the benefit level existing in Period y . Then, according to the NCCI approach, the effect of the first change would be estimated as ${}_1AWB_2 \div {}_1AWB_1$ and the effect of the second change would be ${}_2AWB_3 \div {}_2AWB_2$. The combined effect would be:

$$\frac{{}_1AWB_2}{{}_1AWB_1} \times \frac{{}_2AWB_3}{{}_2AWB_2}$$

Under the alternate procedure, the combined effect would be estimated as ${}_1AWB_3 \div {}_1AWB_1$.

Note that the crucial difference is the use of the wage distribution from Period 1 to evaluate all subsequent changes. If the two-step NCCI approach were used, but using the wage distribution from period 1 both times, then the combined effect would be:

$$\frac{{}_1AWB_2}{{}_1AWB_1} \times \frac{{}_1AWB_3}{{}_1AWB_2} = \frac{{}_1AWB_3}{{}_1AWB_1}$$

which is the alternate procedure. The potential distortion arises not from the intermediate benefit level, but from using the wrong wage distribution to calculate the second benefit change. Assuming average wages usually rise over time, the distortion will usually be related to using an average wage level that is too high when bringing old years on level. Another potential distortion arises from using distributions of affected claimants different from the one that applies to the year being adjusted. However, it would be difficult to postulate any consistent pattern to this potential distortion.

TREND

D. Illustrative Examples

We calculated a number of illustrative examples. In these examples, we used Colorado 1988 average wages and benefit levels as a starting point. We then evaluated the cumulative effect of two hypothetical benefit changes. We considered changes in which the minimum and maximum each increased by 10% per year, as well as changes in the minimum only and the maximum only. We tested wage inflation at 5% and 10% per year. Table 24 displays the estimated combined effects of the two benefit changes applied to losses occurring just prior to the first change.

<u>Wage Inflation</u>	<u>Benefit Changes @ 10%</u>	<u>Overall Effect</u>		
		<u>NCCI</u>	<u>Alternate</u>	<u>% Distortion</u>
5%	Min. & Max	1.0400	1.0378	0.21%
	Min. Only	1.0033	1.0034	(0.01%)
	Max. Only	1.0367	1.0344	0.22%
10%	Min. & Max	1.0423	1.0378	0.43%
	Min. Only	1.0030	1.0034	(0.04%)
	Max. Only	1.0393	1.0344	0.47%

Note that when the minimum and maximum are both adjusted, the distortion is an over-adjustment of losses. However, when the effects of maximums and minimums are isolated, we note that the effect of adjusting the minimums is in the opposite direction. The combined effect of the maximum and minimum is an overadjustment because the maximum affects much more of the wages than the minimum. While this is a function of the Colorado example, we speculate that it is commonly true.

Note also that a higher rate of wage inflation leads to a larger distortion. This also implies that a greater length of time between the year being adjusted and the benefit change leads to a larger distortion. This has implications for trend, since the extent of distortion increases with the age of the year.

TREND

We also tested scenarios in which the rate of compensation increases from 66.67% to 75% and then to 80%. The results are summarized in Table 25.

<u>Wage Inflation</u>	<u>Benefit Changes @ 10%</u>	<u>Overall Effect</u>		
		<u>NCCI</u>	<u>Alternate</u>	<u>% Distortion</u>
5%	Min. & Max	1.2048	1.2032	0.13%
	Min. Only	1.1341	1.1369	(0.25%)
	Max. Only	1.2024	1.2007	0.14%
10%	Min. & Max	1.2063	1.2032	0.26%
	Min. Only	1.1313	1.1369	(0.49%)
	Max. Only	1.2041	1.2007	0.28%

Note that increasing the rate of compensation moderates the upward distortions and increases the downward distortions.

E. Considerations

It is important to consider the likely magnitude of the distortions versus the practicality of correcting them.

1. Likely Magnitude of Distortions

We intentionally postulated large benefit adjustments in our examples. Smaller benefit adjustments would lead to smaller distortions. However, if we postulate that in most states, the maximum affects more wages than the minimum, the NCCI procedure leads to overadjustment of losses to current benefit level, with the extent of overadjustment increasing with the age of the year. This will lead to a downward bias in estimated trend factors. It appears unlikely that the bias will be large, although quantification of the amount of bias in real situations is beyond the scope of this analysis.

TREND

2. Practicality of Alternate Approach

The alternate approach as we have described it would involve, in every rate filing, a full benefit change calculation for each year of data in the trend calculation. Such calculations are frequently quite voluminous, and the practical difficulties of this approach should be recognized.

Note, however, that the "Possible Implementation Procedure" for benefit on level factors described in Section VII.C., would also correct for the distortion discussed in this section. This approach would address using the average wage level from the year being adjusted without addressing the less important issue of the distribution of affected claimants from the year being adjusted.

F. Recommendations

The distortion analyzed in this section likely causes a downward bias in trend indications. While this bias may be quite small, we recommend that additional study be performed to estimate the magnitude of the bias. Should the bias prove significant enough to require correction, it may be possible to develop an approach somewhat more practical than the alternative approach as previously described.

While the illustrations discussed above were calculated within the current NCCI approach (adjusting past losses to current benefit levels), the same calculations could be used under the alternate approach discussed in Section VII. As noted above, a single change in procedure, as described in Section VII.C., could simultaneously address the issues raised in Sections VII and IX. We recommend that NCCI consider implementing a change in procedure along these lines.

(5) Indicated Overall Trend Factor ((1)x(3)) + ((2)x(4)) -----	1.156
(1) + (2)	

SECTION G - DERIVATION OF EFFECT OF TREND FACTOR

Policy year 1987 with an average accident date of January 1, 1988 (Exhibit I-A) and calendar-accident year 1988 with an average accident date of July 1, 1988 (Exhibit I-B) are used in the determination of the indicated change based upon experience (Exhibit I-D). This experience reflects, on average, conditions as of April 01, 1988. The midpoint of the time period for which the revised rates are being proposed is June 01, 1991. The premium level must therefore reflect experience levels which will exist 38 months later than the midpoint of the experience on which the current indication has been derived. The indicated trend factor is 1.156 which represents a trend factor of approximately 4.9% on an annual basis. Since the present rates include a factor of 1.073, the appropriate factor to incorporate the effect of trend into the overall change in premium level is the ratio of these two trend factors: 1.077 (1.077 - 1.156 / 1.073).

(5) Indicated Overall Trend Factor ((1)x(3)) + ((2)x(4))	

(1) + (2)	1.115

Exhibit 3

Texas Bent-line Procedure

TEXAS ADJUSTMENT FOR MEDICAL FEE SCHEDULE GRAPHICAL REPRESENTATION

Texas Overall Trend Without Consideration of Medical Fee Schedule = 1.251 (See Appendix A-V of Rate Level)

Texas Trend With Medical Fee Schedule: .395/.373 = 1.059 Wtd. with Indemnity = 1.158

Adjustment In Rates due to Medical Fee Schedule: 1.158/1.251 = .926 or -7.4%

TEXAS

ADJUSTMENT FOR MEDICAL FEE SCHEDULE

+ C/w Ann. Med. Trend
 Non-Fee Fee
 1.077 1.000
 (7.7%) (0.4%)

+ Tx. Ann. Med. Trend
 Non-Fee
 1.099 \Rightarrow (.272/2)
 (9.9%) = .099

$A = .371$ (Appendix A-V) [TX L.R. at 1/89]

$B = .371 * (1 + 3(.004)) = .375$ [C/w Med Fee L.R. at 1/9]

$C = .371 * (1 + 3(.099)) = .481$ [Tx Non-Fee LR at 1/92]

$D = .371 * (1 + 3(.077)) = .457$ [C/w Non-Fee LR at 1/92]

Difference between Texas & C/w LR = $.481 / .457 = 1.053$

$E = B * 1.053 = .375 * 1.053 = .395$ [Tx Fee LR at 1/92]

Trend from 1/89 \rightarrow 1/92 = $.395 / .371 = 1.065$

\therefore Annual Trend = $.065 / 3 = .022$

(CONTD.)

$$F = .371 * (1 + .25(.022)) = .373 \text{ [Tx Fee UR at 4/89]}$$

$$\begin{aligned} \text{Tx Fee Med Trend from 4/89} \rightarrow 1/92 &= .395 / .373 \\ &= 1.059 \text{ (E/F)} \end{aligned}$$

Overall Tx Trend from 4/89 \rightarrow 1/92 (wtd. w/ indemnity)
With Consideration of Med Fee Schedule = 1.158

Overall Tx Trend from 4/89 \rightarrow 1/92
Without Consideration of Med Fee
(See Appendix A-V) = 1.251

Adjustment in Rates due to Medical Fee
Schedule = $1.158 / 1.251 = .926$ (-7.4%)

10/2/90

Exhibit 4

Excerpt from Maryland rate filing effective 1/1/91

Maryland
1/1/91 Pure Premium Filing
Selection of Trend Factor

The purpose of this memorandum is to explain the analysis which led to the selection of the trend factor.

The trend period in this filing is from 4/1/89, the midpoint of the experience period, to 1/1/92, the midpoint of the period during which rates will become effective. Our goal is to determine whether benefits will rise faster than wages or vice versa during this 33 month period. This is done through the trend factor which is based upon the latest five Maryland policy year loss ratios (Appendix A-V).

Least squares regression curves (linear, exponential, logarithmic) were fit to the five loss ratio points. In each case a credibility value is assigned based upon the goodness of fit of the curve to the actual points. To the extent that state data is not credible countrywide data is employed. The results are displayed on Attachment A. The indicated linear, exponential and logarithmic trends are averaged to obtain the proposed trend factors, .878 and .989 for indemnity and medical respectively. A trend factor less than 1.00 implies that wages are growing at a faster rate than benefits.

We feel that our approach is reasonable, yet conservative for the following reasons:

First, contributing to the downward trend is the fact that the latest loss ratio (Policy year 1988) is extremely low. Policy year 1988 is the only year included in the trend calculation which is entirely subsequent to the enactment of H.B. 239 on 1/1/88. If the low loss ratio for policy year 1988 is a "one time" change due to the 1/1/88 reform then we would expect future policy year (1989, 1990, etc.) loss ratios to be in line with 1988. If this is the case then a trend factor of 1.00 would be appropriate for this filing and a trend factor of less than one would result in an understatement of the true rate level need.

Secondly, having significant impact on the downward trend is the fact that the oldest loss ratio (policy year 1984) is very high relative to the more recent four years (1985 through 1988). For comparison purposes we have calculated trends based upon the latest four points (Attachment A). As expected removal of policy year 1984 has the effect of flattening the downward trends thereby increasing the overall average trend factor from .923 to .945.

SECTION G - DERIVATION OF EFFECT OF TREND FACTOR

Policy year 1988 with an average accident date of January 1, 1989 (Exhibit I-A) and calendar-accident year 1989 with an average accident date of July 1, 1989 (Exhibit I-B) are used in the determination of the indicated change based upon experience (Exhibit I-D). This experience reflects, on average, conditions as of April 1, 1989. The midpoint of the time period for which the revised pure premiums are being proposed is January 1, 1992. The pure premium level must therefore reflect experience levels which will exist 33 months later than the midpoint of the experience on which the current indication has been derived. The selected trend factor is .923 which represents a trend factor of approximately -2.8 % on an annual basis.

	(1) + (2)	

SECTION G - DERIVATION OF EFFECT OF TREND FACTOR

Policy year 1988 with an average accident date of January 1, 1989 (Exhibit I-A) and calendar-accident year 1989 with an average accident date of July 1, 1989 (Exhibit I-B) are used in the determination of the indicated change based upon experience (Exhibit I-C). This experience reflects, on average, conditions as of April 1, 1989. The midpoint of the time period for which the revised advisory loss costs are being proposed is January 01, 1992. The pure premium level must therefore reflect experience levels which will exist 33 months later than the midpoint of the experience on which the current indication has been derived. The indicated trend factor is 1.003 which represents a trend factor of approximately 0.1% on an annual basis.

APPENDIX A-V

CALCULATION OF POLICY YEAR TREND FACTOR (CONTD.)

SECTION F - DETERMINATION OF OVERALL TREND FACTOR

(1) Adjusted Indemnity Losses for Policy Year 1987 valued as of 12-31-88 (See Appendix A-V - Section B)	847,293,975
(2) Adjusted Medical Losses for Policy Year 1987 valued as of 12-31-88 (See Appendix A-V - Section C)	522,618,365
(3) Indemnity Trend Factor	1.157
(4) Medical Trend Factor	1.063
(5) Indicated Overall Trend Factor ((1)x(3)) + ((2)x(4)) -----	1.121
(1) + (2)	

SECTION G - DERIVATION OF EFFECT OF TREND FACTOR

Policy year 1987 with an average accident date of January 1, 1988 (Exhibit I-A) and calendar-accident year 1988 with an average accident date of July 1, 1988 (Exhibit I-B) are used in the determination of the indicated change based upon experience (Exhibit I-D). This experience reflects, on average, conditions as of April 1, 1988. The midpoint of the time period for which the revised rates are being proposed is January 1, 1991. The premium level must therefore reflect experience levels which will exist 33 months later than the midpoint of the experience on which the current indication has been derived. The indicated trend factor is 1.121 which represents a trend factor of approximately 4.4% on an annual basis. Since the present rates include a factor of 1.090, the appropriate factor to incorporate the effect of trend into the overall change in premium level is the ratio of these two trend factors: 1.028 (1.028 = 1.121 / 1.090).

NATIONAL COUNCIL ON COMPENSATION INSURANCE

AGENDA
ACTUARIAL COMMITTEE
MEETING OF AUGUST 25, 1982

AC-82-9

TREND PROCEDURES

Indemnity and Medical Trends

Staff is currently working on completing split indemnity/medical trends on a policy year basis utilizing data valued as of December 31, 1981 for all states. A complete analysis of the results will follow shortly in a separate mailing.

The analysis will include comparisons between:

- a) combined policy year trends based on a weighting of the indemnity and medical trends.
- b) policy year trends computed on a combined loss ratio basis and
- c) calendar year trends.

These trends are all based on a least-squares linear regression approach. A sample of all the trends which will be provided can be seen in attachments 4, 5 and 6.

In order to provide historical results of these comparisons, the following three sets of experience periods will be examined.

	<u>Policy Years Used in Trend</u>	<u>Calendar Years Used in Trend</u>	<u>Attachment</u>
Set I	1976-1980	1977-1981	4
Set II	1975-1979	1976-1980	5
Set III	1974-1978	1975-1979	6

In addition, indemnity/medical and combined policy year trends based on policy years 1973 through 1980 (i.e. eight years of experience rather than five) are also being calculated for comparison with results obtained in set I. Attachment 7 provides a sample of results for these eight point trends.

MINUTES
ACTUARIAL COMMITTEE
MEETING OF JUNE 20, 1990

AC-90-26

AGGREGATE LOSS RATIO TREND

Item 2

Accident Year Trend vs. Policy Year Trend

Background:

The data underlying the current trend procedure are based on the latest five policy year loss ratios. It was suggested at the October 10, 1989 meeting that accident year trend indications be analyzed and compared to policy year data.

At the February 13 and April 4, 1990 meetings, a countrywide analysis of accident year and policy year trend was presented. While the accident year trend was slightly higher in magnitude, the credibility was noticeably lower. Staff demonstrated that policy year data was more credible than accident year using either linear or exponential regressions.

Discussion:

A comparative analysis using eight points of data was performed to determine if more points would help the accident year instability without forfeiting too much responsiveness. Accident year and policy year trend indications for a sample of nine states were computed using both linear and exponential regression models. Loss development based on both the incurred including IBNR and paid to an 8th report methodologies for accident years 1981-1988 and policy years 1980-1987 were utilized. The results of this analysis was included in the Agenda.

When accident year trend indications based on eight data points were compared to accident year trend indications based on five data points, no definite conclusions could be drawn. However, additional years of data did not appear to necessarily improve accident year credibilities.

Staff

Recommendation:

That the Committee discuss.

Committee Action:

Based on the above results, the Committee agreed that accident year data should not be considered for trend at this time.

TECHNICAL APPENDICES

**TREND:
TECHNICAL APPENDIX A**

ALTERNATE TREND TECHNIQUES

I. INTRODUCTION

The first section of this appendix outlines the criteria considered for evaluating the alternate statistical techniques tested in our analysis, including quantitative measures of goodness-of-fit and projection accuracy as well as qualitative and intuitive considerations. The remainder of the appendix presents technical descriptions of the statistical techniques considered for determining the trend in each state and on a countrywide basis. These techniques were selected after a review of actuarial and other relevant literature. These techniques are:

- least squares regression,
- weighted least squares regression,
- non-parametric curve fitting,
- minimum absolute deviation trend line,
- least trimmed squares line fitting,
- exponential smoothing, and
- econometric modelling.

TREND:
TECHNICAL APPENDIX A

II. EVALUATION CRITERIA

Two types of criteria were considered for evaluating the statistical techniques: qualitative and quantitative.

A. Qualitative

Each of the methods identified was reviewed for reasonableness in estimating trends in workers' compensation loss ratios. These reviews included the appropriateness of the underlying assumptions, as well as the strengths and weaknesses of each method. If one method had serious drawbacks and another method included in our analysis had similar strengths, but less significant drawbacks, the former method was rejected. As will be discussed later, two techniques, minimum absolute deviation trend lines and least trimmed squares line fitting, were rejected based on these considerations.

1. Resistance

Resistance is the ability of a method to discard the impact of outliers in an objective manner. If a method is particularly sensitive to outliers, or points that are far from the true underlying trend line due to random variability, it can provide misleading results. There are no common measures of resistance comparable to such measures of goodness-of-fit as R^2 .

In this application, concerns regarding resistance are mitigated by the credibility procedures. To the extent that the loss ratios for a particular state do not follow a common trend line, the state's indicated trend will have lower credibility. NCCI has done some sensitivity testing in which they compare the indicated trend under three scenarios: (1) the next loss ratio is on the fitted trend line, (2) the next loss ratio is 10% above the fitted trend line, and (3) the next loss ratio is 10% below the fitted trend line. An analysis of those calculations indicates that the credibility-weighted trend under the second scenario is only 0.007 greater than under the first scenario. If the average projection period is 2.5 years, the distortion in the projected loss ratio, if the latest loss ratio is randomly high by 10%, is about 0.018 loss ratio points.

**TREND:
TECHNICAL APPENDIX A**

2. Responsiveness

In many actuarial matters, the balance between responsiveness and resistance is a delicate one. It is particularly desirable, in projecting trend, that any changes in the direction or magnitude of the trend line be predicted. If methods that can predict changes in trend can not be identified, methods that respond quickly to such changes are preferred. On the other hand, it is equally important that the trend not be significantly overstated or understated as the result of a single outlier.

The states whose experience was used for testing the various trend techniques were selected carefully to provide a range of situations. In particular, Wisconsin, Illinois, and North Carolina were chosen for their stability. These states' experience were used to test the statistical techniques under "optimal" conditions. At the other extreme, Louisiana and Connecticut were chosen because of the presence of significant economic and benefit changes, respectively. By including these states in our sample, we were able to test each method's ability to respond to changes in trend rates and their resistance.

B. Quantitative

Each of the remaining approaches, i.e., other than the two rejected based on our qualitative evaluation, were applied to the indemnity and medical experience for our sample of states (Connecticut, Florida, Illinois, Louisiana, Michigan, North Carolina, Oregon and Wisconsin) to evaluate their statistical validity. Several measures were considered for evaluating the appropriateness of each model, including:

- accuracy of the forecasts,
- goodness-of-fit to the points in the experience period,
- statistical significance of the trend coefficient, and
- autocorrelation.

TREND:
TECHNICAL APPENDIX A

In making the final selection of methods, we relied primarily on the accuracy of the forecasts made in the sample states.

1. Accuracy

To measure projection errors, we reviewed the average absolute deviation, average mean deviation (sample bias) and average squared deviation of all of the fits performed. These deviations were calculated for forecasts that were two and three years after the end of the experience period used for trend. This represents the general range of prediction periods used in most of the NCCI trend calculations. These deviations are summarized on Exhibit A-1.

2. Goodness-of-fit

Goodness-of-fit was calculated for each technique using R^2 . This quantity was calculated as one minus the unexplained variation divided by the total variation. Unexplained variation is determined as the sum of the squares of the differences between the projections and raw data at each point in the experience period. Total variation is the sum of the squares of the differences between the raw data points and their mean. The formula is as follows:

$$R^2 = 1 - \frac{\text{Unexplained Variation}}{\text{Total Variation}} = 1 - \frac{\sum (\hat{Y}_t - Y_t)^2}{\sum (Y_t - \bar{Y})^2},$$

where \hat{Y}_t is the fitted value at time t , Y_t is the actual value at time t , and \bar{Y} is the mean of the actual values during the experience period used to determine trend. A negative R^2 indicates that the projected values vary more from the raw data than the raw data do from their mean. In other words, the projection technique increases variability around the forecasts.

In order to make the R^2 values more closely comparable, we did not include any weights in the formula, even for those techniques that relied on weighting schemes to determine the trend coefficient. This will tend to make the R^2 values for these techniques slightly lower than the theoretically correct values. Because of the

**TREND:
TECHNICAL APPENDIX A**

method used to include weights in the estimation of the coefficients, the R^2 values would be overstated if the weights were reflected in the calculation of R^2 . The average R^2 value and the range for each technique are shown on Exhibit A-2.

R^2 is commonly used to measure the quality of a projection method. It does not, however, measure the ability of a method to make accurate forecasts. Rather, it measures the ability of the independent variable to explain variations in the dependent variable during the historical experience period. Because past correlation does not necessarily imply causation or future correlation, a high R^2 does not necessarily imply good prediction accuracy.

3. Statistical Significance

The statistical significance of the trend estimate was measured using a t-statistic. This measures the magnitude of the coefficient relative to its standard error. The formula for standard error is:

$$s = \sqrt{\frac{\frac{1}{n-2} \sum (Y_t - \hat{Y}_t)^2}{\sum (t - \bar{t})^2}}$$

where Y_t is the actual value at time t , \hat{Y}_t is the projected value at time t and

\bar{t} is the mean time index. The t-statistic is distributed according to the Student's t-distribution with $n-2$ degrees of freedom, where n is the number of raw data points.

For the non-parametric method, the assumptions underlying the t-statistic do not apply. We therefore calculated a statistic which also measures statistical significance, referred to as Kendall's K statistic¹.

1 Myles Hollander and Douglas A. Wolfe, Nonparametric Statistical Methods, (John Wiley & Sons, New York, 1973), p. 201.

TREND:
TECHNICAL APPENDIX A

An indication that a trend estimate is statistically significant is an evaluation of the ability of a method to differentiate between an underlying trend and random variability in data that has no (i.e., 0%) underlying trend. The fact that a trend coefficient is statistically significant supports the conclusion that trend exists and indicates the degree of accuracy in measuring that trend during the experience period. While this is often an indication that forecasts are likely to be reasonably accurate, it is not necessarily so.

In our tests, the percentage of fits that produced statistically significant trend indications was generally consistent between methods. For most of the methods tested in our analysis, 89% of the indemnity trend indications and all of the medical indications were significantly different from zero.

4. Autocorrelation

Autocorrelation is the tendency of the errors in the forecasts from a projection technique to be predictable. For example, alternating signs of the errors or negative errors for the early points and positive errors for the later points are indications that additional variability can be explained, either through more refined techniques or a different model.

We used the Durbin-Watson statistic to measure autocorrelation in each model. This statistic is calculated as:

$$D = \frac{\sum (\hat{e}_t - \hat{e}_{t-1})^2}{\sum \hat{e}_t^2}$$

where \hat{e}_t is equal to the difference between the actual and the fitted values at time t . It is generally assumed that autocorrelation is not serious if this statistic is between 1 and 3.

The average Durbin-Watson statistic and its range is shown for each method on Exhibit A-2. If autocorrelation is identified, it is an indication that a more complex model may have better prediction accuracy. Given the limited number of points available for these projections, the coefficients of a more complex model would have lower statistical significance and would, therefore, be subject to higher uncertainty.

**TREND:
TECHNICAL APPENDIX A**

III. STATISTICAL TECHNIQUES

This section will provide a detailed description of each of the techniques considered for determining the trend indication in each state. Included in the discussion will be references for complete documentation of each technique. We will also provide our evaluation of each method from a theoretical perspective, as well as a quantitative one.

Because many facets of claim cost inflation are perceived to occur multiplicatively, we included both linear and exponential models in our analyses. The statistical theory underlying exponential models is the same as underlies linear models. Instead of a linear relationship between the loss ratio and time, loss ratios are assumed to increase exponentially as a function of time, as follows:

$$\text{loss ratio} = ab^t$$

Before performing the calculations, natural logarithms of the loss ratios are taken. The form of the equation used in the statistical calculations then becomes:

$$\ln(\text{loss ratio}) = a + bt + e$$

When using an exponential model, it is important to recognize that it is less likely that the error terms, calculated using the actual and predicted loss ratios, are Normally distributed. The implications of this are most important in evaluating the statistical significance of the trend coefficient and in determining the confidence interval around the coefficient. This confidence interval is currently a key component of NCCI's credibility procedure.

A. Least Squares Regression

The current NCCI approach for estimating trend in each state is least squares linear regression. This technique is described in detail as part of our description of the NCCI approach.

TREND:
TECHNICAL APPENDIX A

B. Weighted Least Squares Regression

In order to make the results more sensitive to recent experience, we performed weighted least squares regression. In weighted least squares regression, weights are assigned to each of the observations based on the perceived relevance of each observation to future trends. We arbitrarily selected relative weights of 1, 2, 3, 4, and 5 for each of the points corresponding to time indices 1, 2, 3, 4, and 5, respectively. This will make the estimated trend coefficient more sensitive to the most recent points.

The calculations for this method are the same as for least squares regression with the exception that weights are added to the formulas. The revised formulas are as follows:

$$\hat{c} = \frac{\sum w_i (t_i - \bar{t}) Y_i}{\sum w_i (t_i - \bar{t})^2}$$

$$\bar{t} = \frac{\sum w_i t_i}{\sum w_i}$$

$$\hat{a} = \frac{\sum w_i x_i}{\sum w_i} - \hat{c} \bar{t}$$

where w_i are the weights, $i = 1, \dots, n$, and n is 5 (years). Exhibit A-3 provides an illustration of this technique.

Another interpretation of these formulas is that the number of observations at each time index, each of value equal to the single actual observation, is equal to the weight. For example, the results of the calculations performed herein are the same as those that would be obtained if we had one observation at time index 1, two equal observations at time index 2, three at time index 3, and so on.

TECHNICAL APPENDIX A**

C. Non-Parametric Curve Fitting

"A non-parametric procedure is a statistical procedure that has (certain) desirable properties that hold under relatively mild assumptions regarding the underlying population from which the data are obtained."² One of the techniques included in our analysis is a non-parametric regression procedure.

The estimator of the trend coefficient used for our analysis is attributed to Theil.³ The slope from each of the combinations of points is first calculated as:

$$S_{ij} = \frac{Y_j - Y_i}{t_j - t_i}, \text{ for each } i < j$$

The estimator of the slope coefficient is the median, $\hat{\beta}$, of the S_{ij} . The intercept is calculated as the median of the intercepts implicit in each observation:

$$\text{median of } Y_j - \hat{\beta} t_j$$

Exhibit A-4 illustrates this approach.

The strength of these procedures lies in the mild underlying assumptions and in their resistance to outliers. The assumptions underlying non-parametric regression are that the error terms are mutually independent and that they come from the same continuous population. The assumption of normality of the error terms that underlies least squares regression is eliminated. When performing least squares regression on transformed data, such as for exponential regression, there is strong reason to believe that the error terms of the untransformed data are no longer Normally distributed.

2 Hollander, p. 1.

3 Hollander, p. 205.

TREND:
TECHNICAL APPENDIX A

Because of the reliance on statistics related to medians or ranks rather than means, non-parametric methods are much more resistant to extreme outliers. In fact, for the non-parametric regression method performed for our analysis, the estimator of the trend coefficient does not change if any one of the points is moved, other than the ones used to calculate the median of the slope estimators, S_{ij} , or unless the order of the slope estimates changes. This varies significantly from the results for least squares regression in which the movement of a single point will change the entire fit.

Another important property of trend coefficients is their efficiency. Efficiency relates to the variability around the estimate of the coefficient. That is, an estimator of the trend coefficient is said to be relatively more efficient if, under a set of assumptions, the theoretical variance of the coefficient is less than that for another estimate of the coefficient. If it is assumed that the error terms are Normally distributed, non-parametric regression coefficients are only slightly less efficient than least squares coefficients. On the other hand, non-parametric regression coefficients are much more efficient than those estimated using least squares regression if the distribution of the errors differs significantly from the Normal distribution. It should be noted that these nonparametric estimators are unbiased.

Because of their resistance to outliers, non-parametric methods are not expected to quickly identify changes in trend over time. Thus, one of the key drawbacks of these procedures is the lack of responsiveness relative to other procedures, such as least squares regression.

D. Minimum Absolute Deviation Trend Line

In this technique, a line is fit to the available data using the criteria that the sum of the absolute values of the deviations is minimized, subject to the condition that the average deviation is equal to zero. This differs from the more commonly used least squares regression in which the sum of the squares of the deviations is minimized. This technique was detailed by Charles F. Cook in the 1967 Proceedings of the Casualty Actuarial Society. This paper provides a detailed algorithm for calculating the slope coefficient.

One of the key advantages of this method is the ease of calculation. In fact, Cook maintains that with one possible exception requiring division, "All arithmetic . . . may

**TREND:
TECHNICAL APPENDIX A**

be done mentally."⁴ It also is more resistant to outliers than least squares regression, particularly with respect to points at either end of the experience period.

The method has significant drawbacks. It does not always produce a unique result. In addition, it requires equal intervals between measurements. While the latter drawback is not of particular importance in this application, the former raises serious concerns.

In light of this concern and the inclusion of other methods with similar advantageous characteristics as this one, such as non-parametric curve fitting, we have not performed this technique on the data from the sample states and reject it as a viable alternative to the current approach.

E. Least Trimmed Squares Line Fitting

Least trimmed squares line fitting is similar to least squares regression in that the curve is fit to minimize the sum of the squares of the deviations. It differs, however, in that only the smallest 50% of these squares are used in the determination of the minimum. This technique is described in detail in "Resistant Line Fitting in Actuarial Science," by Rousseeuw, Leroy, and Daniels.⁵

The key advantage of this technique is its resistance. In their paper, the authors describe a measure of resistance, known as the breakdown point. It is the smallest fraction of outliers for which the fitted coefficients are maintained regardless of the magnitude of the outliers. For example, the breakdown point for least squares regression is zero because a single outlier will distort the estimates of the coefficients. This is illustrated in Figure A-1, on the next page. This figure shows the line (identified by "x") fit by least squares regression for the data represented by the plus signs. If a single point, such as the one represented by the asterisk is

TREND: TECHNICAL APPENDIX A

shifted, the entire nature of the curve will change to the one identified with circles.

At the other extreme, non-parametric curve fitting has a relatively high breakdown point, because only a few points are actually used in determining the coefficients.

According to Rousseeuw, Leroy and Daniels, the highest

possible breakdown point is 50%, because after that point, it is impossible to differentiate between random variability and the underlying trend line. Least trimmed squares fitting has the advantage that its breakdown point is 50%.

A significant disadvantage of this approach is its computational complexity. Each of combinations of 50% of the raw data observations must be fit and tested to determine the combination with the minimum squared deviation.

Because of the complexity of computation and the characteristics regarding resistance that it has in common with the non-parametric approach, this method was rejected as a viable alternative to the current NCCI trend approach.

F. Exponential Smoothing Methods

Another family of methods used for prediction are referred to as exponential smoothing methods. In these methods, a weighted average of the historical observations is used to make forecasts. The weights used are of the form $\alpha(1-\alpha)^n$, where n measures the time between the observation being weighted and the current

Figure A-1: Sensitivity to Outliers

**TREND:
TECHNICAL APPENDIX A**

observation. The selection of the weighting constant, α , is somewhat arbitrary. The sensitivity of the results to recent experience will increase as α increases.

Two types of exponential smoothing were tested as part of our analysis: double exponential smoothing and linear exponential smoothing. Each method was tested with a variety of values of α , ranging from 0.1 to 0.7.

1. Linear Exponential Smoothing

In linear exponential smoothing, the location and trend parameters are smoothed separately. The location parameter, S_t , is calculated as:

$$S_t = \alpha X_t + (1-\alpha)(S_{t-1} + T_{t-1}),$$

where X_t is the observed value at time t . This represents the weighted average of the observed value at time t and the value projected at time t based on prior data. The formula for the trend parameter, T_t , is:

$$T_t = \alpha(S_t - S_{t-1}) + (1-\alpha)T_{t-1}.$$

The trend parameter at time t is estimated as the weighted average of the prior estimate of the trend parameter and the difference between the location parameter estimates at times t and $t-1$. Exhibit A-5 shows an example of this method.

Different values of α can be selected for each of the trend and location parameters. Since our analysis focused solely on the trend parameter, we used the same value of α for the location parameter as was used for the trend parameter.

2. Double Exponential Smoothing

In double exponential smoothing, the trend and location parameters are calculated as the function of two intermediate values, S_t and S'_t . S_t is the moving average of the observed values and S'_t is the moving average of the S_t . The same smoothing constant, α , underlies both estimators. The formulas for the weighted averages underlying this method are:

TREND:
TECHNICAL APPENDIX A

$$S_t = \alpha X_t + (1-\alpha)S_{t-1}$$
$$S'_t = \alpha S_t + (1-\alpha)S'_{t-1}$$

The theoretical error of a moving average, with smoothing constant α for a set of data with an inherent trend of b is equal to $\frac{1-\alpha}{\alpha} b$. Thus, S_t understates the observations by $\frac{1-\alpha}{\alpha} b$ and S'_t understates S_t by the same amount. The estimators of the location and trend parameters can therefore be calculated as functions of S_t and S'_t as follows:

$$\text{location parameter} = 2S_t - S'_t$$
$$\text{trend parameter} = \alpha/(1-\alpha)[S_t - S'_t]$$

This method is illustrated in Exhibit A-6.

3. Comparison of Methods

If the observations follow the theoretical trend line exactly, double exponential smoothing and linear exponential smoothing methods will produce identical results. For a given smoothing constant, the estimates of the trend parameter derived from each of the methods applied to data with a random component will be approximately the same, if a long enough experience period is used so that the parameter estimates have stabilized. The location parameter from double exponential smoothing, however, is more sensitive to recent observations than the location parameter derived from linear exponential smoothing. Because the location parameter from double exponential smoothing is a function of the difference between two smoothed averages, one of which has a greater degree of smoothing, it will tend to reflect recent observations.

The strengths and weaknesses of these methods are similar. In both of these methods, the most weight is given to the most recent data point. This allows the methods to be responsive to changes in trend. The amount of the responsiveness,

**TREND:
TECHNICAL APPENDIX A**

however, is dependent upon the choice of α . The selection of α is arbitrary and is generally made through the use of retrospective tests.

For both methods, the results are very sensitive to the selection of initial values of the location and trend parameters, unless a large number of years of experience is available. This is a serious limitation for this analysis, for which it was difficult to obtain data for more than eight policy years. As the Financial Call experience period lengthens to fifteen years, this concern will be mitigated to some extent. An even longer experience period is needed, however, for the projected results to be insensitive to the selection of the initial values.

Our analyses were performed using a five-policy-years experience period for all of our sample states. They were also performed using longer experience periods for three states.

For our analyses, the initial trend parameter value was selected as the average trend between the first and fifth points. The initial location parameter was calculated as the average of each of the first five observations reduced for t years of trend, where t is the time index for each policy year.

G. Econometrics

Econometric modeling is comprised of systems of equations in which the interdependence between the dependent variables and measures of economic conditions are estimated. Econometric models can range from extremely complex systems which evaluate the interdependence of a large number of variables to relatively simple systems in which the interdependence of a single dependent variable and one or two independent variables is measured.

Econometric models are generally specified through the use of regression models which measure the relationship between the dependent variable and the independent variables. A simple example is a multiple regression model in which medical severity is related to time and the medical component of the Consumer Price Index.

TREND:
TECHNICAL APPENDIX A

One of the characteristics of econometric models that separates them from all of the other statistical techniques considered herein is their potential ability to predict turning points in trend lines. In all of the other techniques discussed, the relationship between loss ratios and time is assumed to continue through the rate effective period. To the extent that changes in the rate of trend are related to changes in economic quantities, changes in the rate of trend can be predicted.

A large commitment of time and resources is needed to arrive at a good econometric model. The possible range of economic indices that could be used to project loss ratio changes (or components thereof) is vast. In addition, not all relationships are necessarily intuitively obvious. An example is the dependence of the frequency of workers' compensation claims on unemployment. It can be argued that, during an economic recovery, frequency would be expected to increase due to an influx of untrained workers into the work force. On the other hand, the frequency of claims related to soft tissue injuries may tend to increase during an economic contraction, as unemployed workers seek alternative sources of income.

Often in economic modeling, projections of the independent variable are needed in the equation to project the dependent variable. For example, if medical loss ratio trends were found to be a function of the medical component of the CPI, a projection of the medical component of the CPI would be needed for the rate effective period. It should be noted, however, that, at the time that a rate filing is prepared, more recent data are available for the medical component of the CPI than for historical loss ratios. Also, consumer price indices are not subject to the uncertainty of the more recent projected loss ratios which emanates from the need to estimate development.

An econometric model becomes even more valuable if the independent variable is a leading indicator of changes in the dependent variable. For example, if it were found that the rate of increase in the medical component of the CPI changed a year *before* the change in trend in medical losses, the medical component of the CPI would not need to be projected as far into the future. The projected loss ratio would therefore be subject to less uncertainty.

A full analysis of econometric modeling is beyond the scope of this assignment. We did, however, evaluate a few possible models. Our analysis first focused on

TREND:
TECHNICAL APPENDIX A

identifying interrelationships between losses and economic indices. Examples of these include:

Dependent Variable	Independent Variable	Result
Claim frequency by injury type and in total	Unemployment	Some correlation, except Fatal and PP (volatility)
Medical Severity	CPI - Medical	Very high correlation
Medical Severity	Average Hospital Charges	Very high correlation
Indemnity Severity	SAWW	Mixed
Medical Severity by Injury Type (other than medical-only)	Medical-only Severity	Mixed

These analyses were performed using the available Statistical Plan data because of the additional detail found in the Statistical Plan data regarding frequencies and severities by injury type. Additional information regarding these tests are included in the Technical Supplement to this report.

We then used the Financial Call data in the sample states to evaluate the projection accuracy of a few of these relatively simple models. Our analysis focused primarily on medical loss ratios. Further analysis regarding indemnity and the components of loss ratios (exposure, SAWW, frequency, severity and shifts by injury type) are likely to yield reasonable models.

An example of the model for medical loss ratios is shown in Table A-1, on the next page, for Connecticut. The medical on level loss ratio is adjusted for subsequent changes in the medical component of the CPI and the SAWW. That is, the loss ratio is adjusted to reflect the current levels of these quantities by dividing by the index derived from the medical component of the CPI and multiplying by the index constructed from the SAWW. The indexed medical loss ratios were then regressed against the time index.

**TREND:
TECHNICAL APPENDIX A**

Table A-1: Simple Econometric Model

	(1)	(2)	(3)	(4)	(5)
Policy Year	Medical Loss Ratio	CPI-Medical Index	SAWW Index	Indexed Loss Ratio (1)x(3)/(2)	Time
1983	0.141	0.716	0.783	0.148	0
1984	0.150	0.822	0.849	0.155	1
1985	0.164	0.882	0.904	0.168	2
1986	0.177	0.935	0.953	0.180	3
1987	0.204	1.000	1.000	0.204	4

The result of the (exponential) regression is a curve:

$$\text{indexed loss ratio} = .134(1.079)^{\text{time}}$$

This is equivalent to

$$\text{loss ratio} = \frac{.134 (\text{CPI Index}) (1.079)^{\text{time}}}{(\text{SAWW Index})}$$

In words, this equation indicates that medical loss ratios in Connecticut increased at 7.9% faster each year than the excess of the medical component of the CPI over wage inflation. Projections of future loss ratios can be made using estimates of or actual values of each index in the equation above.

EMPIRICAL BAYESIAN CREDIBILITY

I. THE BÜHLMANN-STRAUB MODEL APPLIED TO TREND

A. Formulation for Loss Ratios by Class

The following formulation of the model, for loss ratios by class, was provided by Meyers¹. After describing the formulation of the model for loss ratios, we will revise the model to apply it to trends.

The formula requires the following data.

1. T years of experience for N classes.
2. The premium for class i in year t (denoted by P_{it}).
3. The loss ratio for class i in year t (denoted by Y_{it}).

The following assumptions are made.

1. The expected loss ratio for class i, μ_i , is randomly selected from a distribution with mean M and variance γ^2 .
2. Each loss ratio, Y_{it} , is randomly selected from a distribution with mean μ_i and variance $\frac{V_i^2}{P_{it}}$.

In assumption (2), the variance is presumed to be inversely proportional to premium volume. In the trend application, we will be interested in a single parameter, the trend rate, in each state. Anticipating the trend application, it is useful to

1 Glenn Meyers, "Empirical Bayesian Credibility for Workers' Compensation Classification Ratemaking," PCAS LXXI, 1984, p. 96.

TREND:
TECHNICAL APPENDIX B

reformulate assumption (2) without the year-to-year variation as follows:

$$\text{Let } P_i = \sum_i P_{ik} \quad (\text{total class premium})$$

$$\bar{Y}_i = \sum_i \frac{P_{ik} Y_{ik}}{P_i} \quad (\text{premium weighted average of } Y_{ik})$$

It follows that the variance of \bar{Y}_i is $\frac{V_i^2}{P_i}$. We can now restate assumption (2) as:

2. Each class total loss ratio, \bar{Y}_i , is randomly selected from a distribution with mean μ_i and variance $\frac{V_i^2}{P_i}$.

The new assumption leaves V_i^2 the same.* It is essentially equivalent except it does not specify the relationship among variances of individual years within a state.

$$\text{Let } \sum^2 = E(V_i^2)$$

* Note that the proportionality constants V_i^2 are allowed to vary by class. This possible variation allows that the postulated relationship between class variance and premium volume may be imperfect. The possible variation in the V_i^2 's is not used in subsequent calculations; rather, the expected value of V_i^2 over all classes is used. To the extent that the V_i^2 's vary, the estimator for $E(V_i^2)$ presented below will still be unbiased, but would have higher variance as an estimator. Variation in the V_i^2 would also reduce the accuracy of individual class credibilities based on premium volume.

**TREND:
TECHNICAL APPENDIX B**

Then the estimator for Σ^2 is

$$\hat{\Sigma}^2 = \frac{\sum_i \sum_t P_{it} (Y_{it} - \bar{Y}_i)^2}{N \cdot T - N}$$

which equals

$$\begin{aligned} & \frac{\sum_i P_i \left(\frac{\sum_t P_{it} (Y_{it} - \bar{Y}_i)^2}{P_i (T-1)} \right)}{N} \\ &= \frac{\sum_i P_i \cdot \hat{\sigma}_{Y_i}^2}{N} \end{aligned}$$

where $\hat{\sigma}_{Y_i}^2$ is the estimated variance of the observed all year class loss ratio \bar{Y}_i .

The estimator of Σ^2 is simply the average of the estimates of V_i^2 in each class.

Next we must estimate γ^2 . The estimate in the class example is as follows:

$$\text{Let } P_{..} = \sum_i \sum_t P_{it} \quad (\text{total premium}),$$

$$P2 = \sum_i P_i^2,$$

TREND:
TECHNICAL APPENDIX B

$$\bar{Y}_{..} = \sum_i \sum_t P_{it} \cdot \frac{Y_{it}}{P_{..}} \quad (\text{premium-weighted average of } Y_{it}),$$

$$W = \sum_i P_i \cdot \frac{(\bar{Y}_i - \bar{Y}_{..})^2}{N - 1}$$

$$\text{and } \hat{\gamma}^2 = \frac{(W - \hat{\Sigma}^2) \cdot (N - 1) \cdot P_{..}}{P_{..}^2 - P_2}$$

The problem can be stated more generally as follows: We are attempting to estimate a parameter for each class (in this case, μ_i , the expected loss ratio) and we have an estimator of the parameter in each class (in this case, \bar{Y}_i). Optimal weights are determined by the relationship between γ^2 , the variance of the distribution of

parameters, and $E\left(\frac{V_i^2}{P_i}\right)$, the expected variance of the distribution of estimators.

We can estimate the necessary variances just as easily if the parameter in question is a trend rate rather than an expected loss ratio.

B. Reformulation for Trend Rates by State

In order to introduce notation for the trend case, we restate the assumptions as follows:

1. The expected trend rate for state i , β_i , is randomly selected from a distribution with mean β and variance γ^2 .
2. Each observed state trend rate, b_i , can be considered as a random selection from a distribution with mean β_i and variance $\frac{V_i^2}{P_i}$.

**TREND:
TECHNICAL APPENDIX B**

$\hat{\sigma}_{b_i}^2$, the estimated variance of the observed trend rate, b_i , is given by the formula

$$\hat{\sigma}_{b_i}^2 = \frac{\sum_i (Y_{it} - \hat{Y}_{it})^2}{(T-2) \sum_i (X_{it} - \bar{X}_i)^2}$$

where the X_{it} are the time indices, Y_{it} are the observed loss ratios and \hat{Y}_{it} are the fitted loss ratios. Then,

$$\begin{aligned} \hat{\Sigma}^2 &= \frac{\sum_i P_i \cdot \hat{\sigma}_{b_i}^2}{N} \\ &= \frac{\sum_i P_i \cdot \sum_t (Y_{it} - \hat{Y}_{it})^2}{N \cdot (T-2) \cdot \sum_i (X_{it} - \bar{X}_i)^2} \end{aligned}$$

Note that the state subscript i has been dropped from the X values since we use the same time indices in all states.

The reformulation of the estimator for γ^2 is straightforward. The \bar{Y}_i are replaced with the b_i .

$$\begin{aligned} \bar{b} &= \frac{\sum_i P_i \cdot b_i}{P_{..}} \\ \text{and } W &= \sum_i P_i \cdot \frac{(b_i - \bar{b})^2}{N-1} \end{aligned}$$

The formula for $\hat{\gamma}^2$ is unchanged. Note that the derivation of $\hat{\gamma}^2$ is based on comparing the observed between state variance (W) with the variance that would be expected if all the β_i were equal ($\hat{\Sigma}^2$).

TREND:
TECHNICAL APPENDIX B

C. Base for Measuring State Credibility

1. Volume

If premium volume is used as the base for measuring credibility, the credibility is assigned according to the formula:

$$Z_i = \frac{P_i}{P_i + K} \quad \text{where } K = \frac{\Sigma^2}{\gamma^2}$$

The estimator for K is: $\hat{K} = \frac{\hat{\Sigma}^2}{\hat{\gamma}^2}$

2. Volume Plus a Constant

In the model using premium volume plus a constant, the estimator of state variance is changed from $\frac{\Sigma^2}{P_i}$ to $\frac{V^2}{P_i} + C$. The credibility formula becomes

$$Z_i = \frac{P_i}{P_i d + K} \quad \text{where } K = \frac{V^2}{\gamma^2} \quad \text{and } d = 1 + \frac{C}{\gamma^2}.$$

To derive estimates for V^2 and C , consider the equation:

$$\hat{\sigma}_{b_i}^2 = \frac{V^2}{P_i} + C + \epsilon_i \quad (1)$$

where $\hat{\sigma}_{b_i}^2$ is the sample variance associated with the state trend estimate b_i and ϵ_i is an error term. We reformulate this as:

$$P_i \hat{\sigma}_{b_i}^2 = V^2 + P_i C + P_i \epsilon_i \quad (2)$$

**TREND:
TECHNICAL APPENDIX B**

We then derive estimates \hat{V}^2 and \hat{C} via linear regression with the quantities $P_i \cdot \hat{\sigma}_{b_i}^2$ as dependent variables and P_i as independent variables.

We chose formulation (2) over formulation (1) since the expected values of the error terms ϵ_i may vary inversely with volume. In our judgment, the regression assumption of identically distributed error terms is more plausible for the terms $P_i \cdot \epsilon_i$ than for the ϵ_i alone. Furthermore, if the constant C is dropped, equation (2) simplifies to:

$$P_i \cdot \hat{\sigma}_{b_i}^2 = V^2 + P_i \cdot \epsilon_i \quad (3)$$

and the regression solution for \hat{V}^2 in (3) is identical to the previously presented estimator for $\hat{\Sigma}^2$.

Note that using regression to solve for \hat{V}^2 and \hat{C} also gives us measurements of the relative significance of these parameters.

3. Quality of Line Fit

The individual estimates of state variance, $\hat{\sigma}_{b_i}^2$, can be used directly to calculate state credibility using the formula: $Z_i = \frac{\hat{\gamma}^2}{\hat{\sigma}_{b_i}^2 + \hat{\gamma}^2}$

This approach will lead to credibilities based directly on the quality of the line fit in each state, analogous to the approach used in the current NCCI classical credibility procedure. Unlike the NCCI procedure, this approach also takes into account, through $\hat{\gamma}^2$, the relative reliability of overall (multiple state) trend.

TREND:
TECHNICAL APPENDIX B

D. Correction for Bias

Consider again the volume based credibility model:

$$\hat{Z}_i = \frac{P_i}{P_i + \hat{K}} \quad \text{where} \quad \hat{K} = \frac{\hat{\Sigma}^2}{\hat{\gamma}^2}$$

The ISO Credibility Subcommittee² and Morris and Van Slyke³ modified the formula for as a correction for bias. Although the estimates of Σ^2 and γ^2 are unbiased, \hat{Z}_i is not. The modified formula, $\hat{Z}'_i = \frac{P_i}{P_i + K} \cdot \frac{N-3}{N} + \frac{3}{N}$ provides an approximate correction based on a number of further simplifying assumptions. It produces a minimum credibility of 3/N and fails when $N \leq 3$. (N is the number of states included in the overall weighted average trend rate.)

The modification always increases the credibility and approaches zero as the credibility approaches one.

We tested the modification in our applications of the volume based model. Since the resulting credibilities were generally very high, the effect of the modification was small.

It is likely that the estimates of Z_i under the alternate credibility bases are biased as well. The extent of such potential biases should be explored if the alternate credibility bases are considered.

**TREND:
TECHNICAL APPENDIX B**

E. The Credibility Complement

In the loss ratio formulation, the observed total loss ratio \bar{M} is equal to the premium weighted average of the observed class loss ratios:

$$\bar{M} = \frac{\sum_i P_i \bar{Y}_i}{P_{..}}$$

However, the credibility complement indicated by the Bühlmann-Straub analysis is not \bar{M} , but rather:

$$\hat{M} = \frac{\sum_i z_i \bar{Y}_i}{\sum_i z_i}$$

the credibility weighted average loss ratio.

In making the analogy to the trend problem, we note that the observed countrywide trend rate (call it b) is not necessarily equal to the premium weighted average of the observed state trend rates. Symbolically:

$$b \neq \text{(in general)} \quad \bar{b} = \frac{\sum_i P_i b_i}{P_{..}}$$

However, if we make the simplifying assumption that premium is constant over time in each state (which assumption is consistent with the use of ordinary least squares to determine the trend rate), then it can be proved that the equation $b = \bar{b}$ holds. To the extent that b and \bar{b} differ in practice (in our tests, the difference was always negligible), \bar{b} may be a better estimator of β (the true average countrywide trend), since it is not distorted by shifts in volume from state to state.

TREND:
TECHNICAL APPENDIX B

With the above simplifying assumption, the analogy between the class problem and the trend problem holds. Thus, the appropriate countrywide complement is the credibility weighted average trend rate:

$$\hat{b} = \frac{\sum_i z_i b_i}{\sum_i z_i}$$

**TREND:
TECHNICAL APPENDIX B**

II. USING HISTORICAL PREDICTION ERRORS

This section develops in greater detail an idea discussed in Section V for estimating variances for use in Bayesian credibility formulas. Our analysis did not include testing of this technique. The data base we received from NCCI did not have enough years to apply this method; however, it appears that NCCI could develop an adequate data base.

Under this approach, the relative variances associated with state and countrywide trend projections, α^2 and γ^2 , respectively, would be estimated by measuring actual prediction errors.⁴ The measurement requires a data base longer than the period used for fitting trend. A reasonably long period would be preferable since a longer period produces more readings of prediction errors and provides measurements over a greater range of economic conditions.

A. Measuring Prediction Errors

Let Y_{it} and \hat{Y}_{it} represent the actual and fitted loss ratios for state i in year t . Let the fitting period run from year a to year b and let c represent the number of years after

4 Prediction error, the difference between a predicted loss ratio and an actual loss ratio, consists of two components: (1) the difference between the predicted loss ratio and the true mean loss ratio ("parameter" error); and (2) the difference between the actual loss ratio and the true mean loss ratio ("process" error). By definition, the process error cannot be predicted; therefore, the variances used in the credibility formula would ideally be based on parameter error only. Since the method described in this Appendix is based on prediction errors, both state and countrywide variances will be overstated by the same amounts, the process variance. The process variance will act as a "ballast" biasing credibilities toward 50%. If this effect is significant, an independent estimate of the average process variance could be made and subtracted from countrywide and average state mean square prediction errors.

TREND:
TECHNICAL APPENDIX B

year b that we wish to project. The projected loss ratio for year b+c is then:

$${}_i Y_{a,b,c}^* = Y_{ib} \frac{\hat{Y}_{i,b+c}}{\hat{Y}_{ib}}$$

The corresponding prediction error is then

$${}_i ES_{a,b,c} = {}_i Y_{a,b,c}^* - Y_{i,b+c}$$

For countrywide data, let Y_t and \hat{Y}_t represent actual and fitted loss ratios for year t. Again, letting the fitting period run from a to b, the projected loss ratio for state i in year b+c is:

$${}_i Y_{a,b,c}^{**} = Y_{ib} \frac{\hat{Y}_{b+c}}{\hat{Y}_b}$$

where the double asterisk denotes that countrywide data has been used to project state results.

The corresponding prediction error is:

$${}_i EC_{a,b,c} = {}_i Y_{a,b,c}^{**} - Y_{i,b+c}$$

Note that to approximate NCCI ratemaking procedures, the approach for calculating projected loss ratios uses the product of an "experience period" loss ratio (i.e. the loss ratio for the last year of the fitting period) and a "trend factor" (i.e. the ratio of the fitted loss ratio for the projection year to the fitted loss ratio for the experience period).

**TREND:
TECHNICAL APPENDIX B**

B. Mean Square Prediction Errors

Given that the NCCI trend periods are usually between two and three years, we are interested in two and three year prediction errors. We would then calculate the ESs and ECs for all available two and three year projections. The number of two and three year projections should be the same for all states. Let the observed mean square countrywide projection error be denoted \overline{EC}^2 , calculated as the unweighted average of the EC^2 for all available ECs.

For each state, denote the state mean square error \overline{ES}_i^2 , the unweighted average of the ES^2 available for that state.

C. Credibility Formulas

Given an adequate data base, \overline{EC}^2 will be an average of many readings, sufficiently reliable to use in credibility formulas. On the other hand, the \overline{ES}_i^2 in each state will be based on only few readings and will not be sufficiently reliable. To get a better measure of $E(\overline{ES}_i^2)$ in each state, we will need a base which measures the relative variance from state to state. We will consider the three credibility bases discussed earlier: volume, volume plus a constant, and quality of line fit.

1. Volume

Denoting state volume by P_i , we assume that $E(\overline{ES}_i^2) = \frac{C}{P_i}$. We estimate C as:

$\hat{C} = \frac{\sum_i P_i \cdot \overline{ES}_i^2}{N}$, where N is the number of states. We then assign credibility according to the formula:

$$\hat{Z}_i = \frac{P_i}{P_i + \hat{K}}, \quad \text{where } \hat{K} = \frac{\hat{C}}{\overline{EC}^2}$$

**TREND:
TECHNICAL APPENDIX B**

2. Volume plus a Constant

In this alternative approach, we assume that $E(\overline{ES}_i^2) = \frac{C_1}{P_i} + C_2$

Using actual values of \overline{ES}_i^2 and introducing an error term ϵ_i , we have:

$$\overline{ES}_i^2 = \frac{C_1}{P_i} + C_2 + \epsilon_i$$

$$\text{or } P_i \overline{ES}_i^2 = C_1 + P_i C_2 + P_i \epsilon_i \quad (4)$$

Using the formulation in equation (4), estimates \hat{C}_1 and \hat{C}_2 are derived by linear regression. Credibility is then assigned according to the formula:

$$\hat{Z}_i = \frac{P_i}{P_i \hat{d} + \hat{K}}$$

$$\text{where } \hat{K} = \frac{\hat{C}_1}{\overline{EC}^2} \text{ and } \hat{d} = 1 + \frac{\hat{C}_2}{\overline{EC}^2}$$

3. Quality of Line Fit

The residual sum of squares from the line fit for state i (SSR_i) can also be used as a predictor of $E(\overline{ES}_i^2)$. In this case we assume that $E(\overline{ES}_i^2) = C \cdot SSR_i$

$$\text{and we can estimate } C \text{ by } \hat{C} = \frac{\sum_i \left(\frac{\overline{ES}_i^2}{SSR_i} \right)}{N}$$

Credibility would be assigned according to the formula:

$$\hat{Z}_i = \frac{\overline{EC}^2}{\hat{C} \cdot SSR_i + \overline{EC}^2}$$

TREND:
TECHNICAL APPENDIX B

D. Bias in Credibility Estimates

As noted earlier in this Appendix, even if \overline{EC}^2 and the estimates of the various proportionality constants are unbiased, the estimates of Z_i will not, in general, be unbiased. The extent of potential bias and corrections for these biases should be explored further.

**TREND:
TECHNICAL APPENDIX C**

DESIGN OF TEST FOR PREMIUM ON LEVEL FACTORS

This Appendix provides greater detail on our test for distortions in premium on-level factors as discussed in Section VIII.

I. NOTATION

Exposures (payroll) for class i , period j : ${}_jE_i$

Total payroll for period j : ${}_jE = \sum_i {}_jE_i$

Rates for class i , effective date d : ${}_dR_i$

Average rate for effective date d , calculated using exposures for period j :

$${}_jAR_d = \sum_i {}_jE_i \cdot \frac{{}_dR_i}{{}_jE}$$

II. EXPOSURE/RATE DATA

For each state, NCCI provided us with the quantities ${}_jAR_d$ for six or seven policy periods and at least seven years of rates. We also received total payroll for each policy period.

III. FORMULA FOR PREMIUMS AT PRESENT RATES (PPR)

$$PPR_j = {}_jE \cdot {}_jAR_{d'}$$

where d' is the effective date of the current rates.

TREND:
TECHNICAL APPENDIX C

IV. CALCULATION OF OVERALL EFFECTS OF RATE CHANGES

For each effective date, we identified the policy periods which would likely be used to balance the rate change, i.e., those most nearly averaging 4.5 years prior to the rate change (denoted as periods a, b, c).

Then our approximation of NCCI's estimated overall rate change for effective date d is:

$$\frac{{}_aAR_d + {}_bAR_d + {}_cAR_d}{{}_aAR_{d-1} + {}_bAR_{d-1} + {}_cAR_{d-1}}$$

V. CALCULATION OF ON LEVEL PREMIUMS

We calculated on level factors for each policy period (denoted ${}_jOL$) based on the overall rate changes calculated above and standard methodology.

For each policy period, we calculated average rates in effect. For example, if policy period j begins three months before effective date d , then the average rate during policy period j is: ${}_jAR = (0.25) * {}_jAR_{d-1} + (0.75) * {}_jAR_d$.

The on level premium for policy period j is: ${}_jE * {}_jAR * {}_jOL$.

(As part of an NAIC examination of NCCI, Milliman & Robertson, Inc. has completed a study of the trend ratemaking procedures of the NCCI. The purpose of this technical supplement is to provide supporting data and calculations underlying the study).

TECHNICAL SUPPLEMENT**

**TREND:
TECHNICAL SUPPLEMENT**

Notes on Exhibit I

Indemnity Pages

1. States included are those included in the "trend data base" provided to us by NCCI.
2. Five year on level premium.
3. Slopes of the fitted lines in each state, corresponding to the values b_i defined on page B-4. For exponential fits, values are the slopes of the lines fit to the natural logarithms of the loss ratios.
4. Values for time have been set to -2, -1, 0, 1, 2 so that these values are fitted loss ratios in the middle year (logs of loss ratios for exponential fits).
5. The standard error of the trend rate, corresponding to the value $\hat{\sigma}_{b_i}$ per page B-5.
6. The credibility calculated using the current NCCI credibility formula.
7. The Bayesian credibilities using the countrywide complement, calculated using one of the formulas for Z_i presented on pages B-6 and B-7.
8. Values in columns (2) through (5) based on countrywide data. Values in columns (6) and (7) are arithmetic averages of the numbers above them.
9. The value $\hat{\Sigma}^2$ per page B-5.
10. The value W per page B-5.
11. The value γ^2 per page B-4.

**TREND:
TECHNICAL SUPPLEMENT**

Version 1 (Sheets 1-9 plus 49)

12. The value K per top section of page B-6.
13. The value \bar{b} per page B-5 (premium weighted average of the b_i).

Version 2 (Sheets 19-27)

12. The value C per page B-6.
13. t-statistic for C. Values greater than 2.0 are generally considered statistically significant.
14. The value K per bottom section of page B-6.
15. The value d per page B-6.
16. See Version 1, item (13).

Version 3 (Sheets 37-42)

12. See Version 1, item (13).

Medical Pages

- (1) through (7) Same as indemnity pages.
- (8) through (11) The Bayesian credibilities using the listed group of states for the complement. "Fee Group" corresponds to states with "effective" fee schedules per NCCI. The groupings used here are those identified by NCCI in the "trend data base" provided to us. They do not correspond exactly to the groupings identified in Section III-G, Table 2.
- (12) through (16) Values in columns (2) through (5) based on the combined data of the groups of states identified. Values in columns (6) through (11) are

**TREND:
TECHNICAL SUPPLEMENT**

arithmetic averages of the numbers above them for states in the groups identified.

Version 1 (Sheets 10-18 plus 50)

(17) through (21) Same as Indemnity Version 1, items (9) - (13)

Version 2 (Sheets 28-36)

(17) through (24) Same as Indemnity Version 2, items (9) - (16)

Version 3 (Sheets 43-48)

(17) through (20) Same as Indemnity Version 3, items (9) - (12)

CLASSIFICATION RATEMAKING

I. INTRODUCTION

An integral aspect of the National Council on Compensation Insurance (NCCI) ratemaking efforts, as described in detail in Section IIA of this examination report, is the allocation of the overall rate level change to individual classifications. This step in the ratemaking process is important in determining the relative equity of the premiums to be charged to members of each rating class.

A commonly accepted goal of any ratemaking process is to be responsive to current conditions without introducing unnecessary instability in the rating structure. For classification ratemaking more emphasis is frequently placed on stability than on responsiveness. Therefore, a thorough evaluation of a classification ratemaking procedure must include an analysis of how equity and stability are balanced within the system of calculations.

Section IIB-4 of the National Association of Insurance Commissioners (NAIC) request for proposal to examine the NCCI specifically addresses the issues of equity and stability in the workers compensation ratemaking system. The NAIC request for proposal and M&R's response to that request, recognized the complex nature of the system and that all facets of the procedure are not equally important. Therefore, the examination was to concentrate on the following three objectives that are considered especially relevant to the issues of equity and stability:

Objective 4a - Study and recommend alternatives to NCCI's (1) current approach to credibility, (2) practice of using three years of data as a sole indicator for most national pure premium indications and as a basic unit for determining pure premiums at the state level, and (3) loss limitations used in those calculations.

Objective 4b - Determine if the NCCI's procedure for determining industry group relativities could be enhanced by using more years of data. The analysis also will address variances in approach between large and small states.

Objective 4c - Determine if the NCCI should adjust losses to a current or common level by trending individual years separately rather than by applying an aggregate trend factor to all years combined.

CLASSIFICATION RATEMAKING

We addressed these objectives theoretically and empirically. We first reviewed the theory underlying the current methodology to identify the procedures used and to understand their impact on NCCI rates. We then identified specific alternative procedures to be tested.

We then designed empirical tests of both the equity, measured in terms of the accuracy of forecasts relative to actual experience, and stability, measured by the consistency of the forecasts from year to year, to compare the performance of the current NCCI approach with that of those alternatives. In addition to supporting the conclusions reached in this examination, we believe that these empirical tests can be used by NCCI, regulators and other analysts as a framework for future tests of alternatives to the NCCI methodology.

In addition to the stated objectives 4a, 4b, and 4c, we have also reviewed the loss experience of classes that comprise the "All Other" industry group in several sample states. The objective of this supplemental analysis was to determine if the wide variety of exposures included in this group can be better segregated in a consistent manner to improve the accuracy of the ratemaking system. Finally, we identified a number of other areas for further review outside the scope of objectives 4a, 4b, 4c.

CLASSIFICATION RATEMAKING

II. CONCLUSIONS AND RECOMMENDATIONS

In our examination, we reviewed specific alternatives to the current NCCI classification ratemaking methodology in the following areas:

- A. Project Objective 4a:
 - 1. Credibility formula
 - 2. Length of the experience period
 - 3. Limitation of losses
- B. Project Objective 4b:
 - Industry group relativities
- C. Project Objective 4c:
 - Application of trend factors
- D. Other Specific Alternatives Relative to:
 - 1. Composition of "All Other" industry group
 - 2. National relativities in classification rating.

In addition to testing specific alternatives in the areas listed above, other subjects arose during the course of our review. These included:

- E. Other Items
 - 1. An apparent inconsistency of loss limits used in the various components of partial pure premiums
 - 2. Issues relating to the treatment of 'F' classifications
 - 3. Observations regarding the treatment of losses in excess of the limits used in state classification experience
 - 4. Weighting used in calculating test correction factors
 - 5. A review of additional calculations supplied by NCCI

CLASSIFICATION RATEMAKING

In this part of this section of this examination report, we will present a brief discussion of our conclusions in each of these areas followed by specific recommendations where appropriate. We direct readers to more complete discussions of those conclusions contained later in this section of this examination report.

A. Project Objective 4a

1. Credibility Formula

We tested several alternatives to NCCI's classification ratemaking credibility formulas. None of the alternatives tested proved to be generally more accurate or more consistent in identifying relative cost differences than the current formula.

A more detailed discussion of our conclusions in this area is found on pages 53 through 56.

2. Length of the Experience Period

Our tests indicated that increasing the length of the experience period used in calculating industry group differentials and indicated partial pure premiums from three to five years enhances the consistency of the ratemaking methodology in identifying relative loss cost differences among classes. Furthermore, our accuracy tests, which were necessarily limited to first report data for only one policy year and five states, suggest that this aspect of the ratemaking process would also improve with a longer experience period. Additional calculations provided by NCCI using other states, more mature data and adjusting for expected development generally appear to support these conclusions, though not unanimously. We recognize the possibility, however, that the tests using other policy years, more mature data and other states may result in different conclusions.

We recommend that NCCI increase the number of years of experience used in state classification ratemaking from three to five unless results of additional accuracy tests by NCCI using the methodology described here and incorporating data at second report and later, are not consistent with the results we obtained.

Our recommendation does not mean we believe five years is sufficient. We did not test longer experience periods due to practical limitations imposed by available data. NCCI should test the appropriateness of using more than five years of data, subject to data

CLASSIFICATION RATEMAKING

limitations and consideration of the relevancy of experience too distant from the ratemaking effective date.

A more detailed discussion of our conclusions in this area is found on pages 50 and 51.

3. Limitation of Losses

None of our alternatives to the current loss limitations proved to significantly improve upon the current methodology. However, use of half the current loss limitation may nominally increase the accuracy and consistency of the process assuming no change in the current treatment of losses above the limit. We understand that NCCI is currently considering basing the loss limitation on fifty times the average cost for all claims in a state as compared with the current limitation based on the average serious claim size. NCCI indicates that this new limitation will result in limits equal to roughly half the current limitation. We agree with this proposed course of action but recognize questions regarding treatment of losses above the limit.

A more detailed discussion of our conclusions in this area is found on pages 51 through 53 and 54 through 55.

B. Project Objective 4b - Industry Group Relativities

In contrast to our conclusions in Objective 4a, item 2 above, none of the alternative number of years of experience tested proved to generally provide more accurate identification of relative differences among industry groups than the others. We note that it is not uncommon to use successively more years of experience in property and casualty insurance ratemaking as the level of detail required increases. For example, using three years of experience for industry group differentials would not be inherently incompatible with using, say, five years of experience at the class level.

A more detailed discussion of our conclusions in this area is found on pages 62 through 64.

C. Project Objective 4c - Application of Trend Factors

We recommend that NCCI trend the losses for each policy year separately in the classification ratemaking methodology. This change is not technically complex to

CLASSIFICATION RATEMAKING

implement and any additional costs would be more than offset by the added consistency achieved by the change. If NCCI increases the number of years used in classification ratemaking as recommended above, it is likely that differences between the current and the alternative trend application would be more significant.

A more detailed discussion of our conclusions in this area is found on page 62.

D. Other Specific Alternatives

1. Composition of the "All Other" Industry Group

We reviewed the composition of the "All Other" industry group. We recommend that NCCI further investigate subdividing this industry group into smaller, more homogeneous industry groups. Given the size of the "All Other" group, we believe that the resulting sub-groups could result in industry groups large enough to have full statistical credibility.

A detailed discussion leading up to the above conclusions is presented on page 66. Using data from Maine, Michigan, and Pennsylvania, we show that a clerical office workers industry group could be created from the current "All Other" group. Both the new clerical group and the remaining "All Other" classes would be more homogeneous and large enough to warrant full credibility. We stress that other sub-groups are possible and could vary by state.

Although the scope of this study was the "All Other" industry group, this kind of analysis could be extended to the "Manufacturing" and "Contracting" industry groups to better segregate common occupational activities.

2. Alternate National Partial Pure Premiums

We tested an alternative to the current pure premiums indicated by national relativities. This alternative added a second component to the calculation of those partial pure premiums, giving the state's region more weight. We found, however, that this resulted in little change in final rates compared with the current methodology. We do not recommend changing the formula to reflect regional experience.

A more detailed discussion of our conclusions in this area is found on page 71.

CLASSIFICATION RATEMAKING

E. Other Areas

1. Consistency in Loss Limitations

NCCI uses limited losses to calculate two of the three components of partial pure premiums determined by formula while the third is not limited. This results in lower partial pure premiums for fully credible classes and higher partial pure premiums for non-fully credible classes compared to the result if limited losses were used in all three components.

We recommend that NCCI adopt a methodology that does not suffer from this potential bias. One alternative could be to replace the partial pure premiums used in the calculations by their relativities to statewide average partial pure premiums calculated using the experience period payrolls as weights. Another alternative that was suggested would be to limit the current on-level partial pure premiums to reflect the limitation of losses.

A more detailed discussion of our conclusions in this area is found on pages 26 through 28.

2. 'F' Classifications

The current NCCI approach does not include a provision for trend in loss costs for 'F' classifications but such trend can influence costs for these classes. We recommend that NCCI modify its procedure to reflect the effect of such trend.

We recommend that the F-Class financial calls either be enforced, validated and utilized in ratemaking, or be eliminated. This recommendation is similar to the corresponding recommendation contained in the Overall Rate Level portion of Volume III to Section I which addressed the evaluation of data collection and data quality. Page 2 of that reference identifies as one key weakness that "NCCI collects F-Class financial call data which is not used to determine rate level changes and is not currently validated". A key recommendation on page 2 is that: "NCCI should examine their current list of financial calls. Calls which are not validated or required should be eliminated." Pages 6 and 7 of that volume discuss the collection process for F-Class financial calls.

A more detailed discussion of our conclusions in this area is found in Appendix D.

CLASSIFICATION RATEMAKING

3. Losses in Excess of Limitations

Our tests indicate that different classes may have different expected losses above the loss limitation. Insurance spreads risk among various insureds, and as such must always strike a balance between pooling and equity for a specific insured or class. At one extreme, all insureds could be charged the same price. At the other, all could be charged different prices, each reflecting their own costs. The first extreme emphasizes pooling whereas the other equity.

The NCCI method of providing for losses in excess of the loss limitation in classification data spreads the provision for large losses almost uniformly among all classes in an industry group. The results of our review of losses above the limitation indicates that different classes may expect different losses in excess of the limitation. We recognize that these indications could change if these tests are conducted on a larger database than that used in this examination.

We thus recommend that NCCI take two steps:

- a. NCCI should further examine the extent that classes have different expected losses in excess of the limitation contained in classification ratemaking data.
- b. With this additional information, NCCI should determine whether to continue the present procedure of including uniform provision for excess losses by industry group or to revise its procedures to recognize differences, if any, in excess loss potential by class. These conclusions and recommendations may appear to be contradictory to those presented in the Limitation of Losses section on page 5 above. Those earlier recommendations are based on the premise that the current methodology for excess losses continues. The conclusions and recommendations here address whether or not actual losses seem to be consistent with that assumption.

A more detailed discussion of our conclusions in this area is found on page 76.

4. Weighting Used in Test Correction Factors

We recommend that the test correction factor be calculated using the latest available single year of on-level premium by class as weights. This will reduce the potential for failing to accurately achieve the targeted rate change in states with changing class distributions. This

CLASSIFICATION RATEMAKING

change is more important if the number of years used in classification ratemaking is increased.

A more detailed discussion of our conclusions in this area is found on page 30.

5. Additional Information Prepared by NCCI

In the later stages of this examination, NCCI prepared additional tests of the relative accuracy from the use of five years of data as compared with the current three years. We addressed this additional information in pages 77 through 79 of this examination report. The results of these additional tests seem generally to agree with the indications of our original tests.

CLASSIFICATION RATEMAKING

CLASSIFICATION RATEMAKING

III. DISCUSSION OF ALTERNATIVES TO NCCI METHODOLOGY

Our report in Section IIA of the ratemaking part of this examination contains a complete and detailed description of the current NCCI classification methodology. We will not repeat the contents of that report here; rather we will highlight certain aspects of the methodology that pertain to this section of the examination.

The initial scope of our examination was limited to the following aspects of the current NCCI classification ratemaking methodology:

- A. Credibility formula
- B. Length of the experience period
- C. Limitation of losses
- D. Industry group relativities
- E. Application of trend
- F. Alternative to pure premiums indicated by national relativities

Our analysis of these components of workers compensation classification ratemaking involved a comparison of the accuracy and consistency of the current approach with that of specific alternatives to each. Our approach involved direct empirical testing of the current methodology with specific alternatives. To best isolate the effects of each alternative, our tests varied only one aspect of the current procedure at a time. As such, simultaneous implementation of two or more alternatives may not produce results parallel to the implementation of either of those alternatives separately.

In the course of this examination, the Examination Oversight Group asked us to address additional specific questions in the following areas:

- G. 'F' classifications
- H. Segregation of classes within the "All Other" industry group

In addition, we noticed other aspects of the current NCCI methodology that were worthy of comment in the following areas:

- I. Other aspects
 - 1. An apparent inconsistency of loss limits used in the various components of the partial pure premiums

CLASSIFICATION RATEMAKING

2. Losses in excess of limitations
3. Weighting used in calculating test correction factors
4. Development of losses incorporated in classification ratemaking
5. Volatility in classification rates arising from that in national experience
6. Swing limits

Our analysis of item F, above, also included empirical testing of specific alternatives similar to items A-E while our analysis of items G, H, and I did not include these tests.

The following paragraphs contain discussions of key aspects of the current NCCI methodology and alternatives to the NCCI methodology in the areas outlined above. Later portions of this section of this examination report will address data, the methodology and more complete conclusions of our analysis in each of these areas.

A. Credibility Formula

The purpose of credibility weighting in class, or other, ratemaking applications is recognition of the believability of the data or indications under review. Generally, averages taken from small volumes of data tend to be volatile while those taken from large volumes tend to be more stable. This is a reflection of the law of large numbers in statistics.

Credibility weights used by actuaries are a means to represent this concept in quantitative terms. In most applications the choice of the particular credibility formula is largely judgmental, reflecting a balance between stability and responsiveness in the ratemaking process. The rates for fully credible classes are affected by the credibility procedure because the weighted average of indicated changes for both fully credible and partly credible classes is balanced to the targeted overall rate change. Thus, use of a proper credibility procedure is important to all classifications.

In calculating the pure premiums derived by formula, NCCI uses a credibility weighting procedure. The credibility applied to an individual class depends on the volume of expected losses for that class. The credibility applied to pure premiums indicated by

CLASSIFICATION RATEMAKING

national relativity is based on the number of claims that were used in calculating that pure premium.

The formula that is used in both cases is:

$$\text{Credibility} = (\text{Volume/Full Credibility Standard})^{2/3}$$

where Volume indicates either expected losses for indicated pure premiums or number of claims for pure premiums indicated by national relativity and, in no case is the credibility allowed to exceed one. The credibility assigned to pure premiums indicated by national relativity is further limited to one-half of the complement of the credibility assigned to the indicated pure premium.

This formula indicates four essential properties of the current NCCI credibility procedure:

1. Credibility is based on the level of expected losses or, in the case of pure premiums indicated by national relativity, number of claims,
2. There is a full credibility standard; classes with expected losses or claim counts above that amount are given full, or 100%, credibility,
3. Partial credibility is assigned to classes with less than the full credibility level experience based on the ratio of the expected losses or number of claims to the full credibility standard,
4. The amount of credibility added by a dollar of added expected losses or a single claim decreases as the total amount of expected losses or claims increases. For example, if the full credibility standard were \$100, \$0 in expected losses would be given 0% credibility, \$1 in expected losses would be given 4% credibility, but \$2 in expected losses would be given 7% credibility. Here the first \$1 of expected losses increases credibility by 4%, the next \$1 increases it by 3%.

There have been numerous papers addressing credibility formulas and their application. The credibility formulas in use today seem to fall into two families. The first, to which the current NCCI formula belongs, which we will label classical credibility, is in the form:

$$\text{Credibility} = (\text{Volume/Full Credibility Standard})^P$$

CLASSIFICATION RATEMAKING

with the credibility limited to be between 0 and 1. The power used, p here, is usually taken to be between 0 and 1. This choice of power insures that the fourth property above holds.

The chart below compares the credibilities assigned to various volumes of experience for several values of p . In all cases we used the same arbitrary full credibility standard of \$1 million. For any value of p between 0 and 1, a lower value of p produces a higher credibility for any fixed volume of experience as long as the volume is below the full credibility standard.

CLASSIFICATION RATEMAKING

The well known statistical property known as the "law of large numbers" implies that the larger the sample size the less the sample average can be expected to vary from the underlying population average. Under rather broad assumptions the variance of the sample average is inversely proportional to the square root of the sample size. This leads to the common use of the square root in many credibility applications.

On the other hand, the power used by NCCI is 2/3. In our review, we were unable to find discussion or documentation from the NCCI of the origin of the 2/3 power. It is possible that it was selected for the balance between stability and responsiveness that it brings to the ratemaking methodology.

The second parameter in this general credibility formula is the full credibility standard. With suitable statistical assumptions, the full credibility standard can be set to result in sample averages that are within a certain tolerance of the true mean a certain percentage of the time. See, for example, An Introduction to Credibility Theory by L.H. Longley-Cook (1962). In practice, however, this value often reflects the ratemaker's judgment of the volume of experience sufficient to provide reasonably accurate estimates.

The NCCI full credibility standard for serious pure premiums is twenty-five times the average serious case, for non-serious pure premiums it is three hundred times the average non-serious case and for medical pure premiums it is 80% of the non-serious credibility standard. The full credibility standards for pure premiums indicated by national relativity are twenty-five serious cases for serious pure premiums, three hundred non-serious cases for non-serious pure premiums and three hundred total serious and non-serious cases for medical pure premiums.

We understand that these full credibility standards were judgmentally derived and have been consistently applied for a considerable amount of time. We have not, however, seen discussions regarding the rationale behind these full credibility selections.

Another form used in calculating credibilities, that we will label the ratio formula, can be expressed as:

$$Z = \text{Credibility} = \frac{n}{n+K}$$

where K is some constant and n is a measure of the volume of experience.

CLASSIFICATION RATEMAKING

Hans Bühlmann ("Experience Rating and Credibility", The Astin Bulletin, Volume IV, 1967) has shown that with the appropriate choice of the constant K, which he provides in that paper, Z provides the best linear approximation of the form:

$$a + Z\bar{x}$$

to the expected value of the underlying distribution. Here \bar{x} is the average of the observed sample of size n.

As with the power form for credibility with the power between 0 and 1, each additional unit of volume results in successively less additional credibility. Unlike the power form described above, there will be no class whose experience will be fully credible. That is, the value of the credibility will be less than 1 if K is chosen to be any positive number. If K is selected to be 0 then all volumes of experience will be fully credible.

K, however, does affect the shape of the resulting credibility curve. If K is small, relatively small volumes of experience are required to reach specified credibility levels (less than 1). If K is large, relatively large volumes are required. The following chart compares the credibilities corresponding to various choices of the constant K:

CLASSIFICATION RATEMAKING

These two families of credibility formulas generally will produce different credibilities among the various sized classes, even if they give the same average credibility overall. This is shown in the chart:

CLASSIFICATION RATEMAKING

Here we arbitrarily selected a full credibility standard of 1,000,000 for the power formula and found the value of K of 150,353 that would result in the same average credibility over a uniform distribution of volumes between 0 and 2,000,000. As can be seen here, in this case, the power formula used by NCCI tends to give more credibility to larger volumes and less to smaller volumes than the ratio formula.

There are other approaches that have been used to calculate credibility. One family of approaches uses Bayesian statistical analysis with assumptions regarding underlying statistical distributions to derive best credibility formulas under various conditions. Such an approach was presented in a paper by G. Meyers "Empirical Bayesian Credibility for Workers' Compensation Classification Ratemaking", Proceedings of the Casualty Actuarial Society, Volume LXXI (1984), pages 96-121. The formula for the credibility Z presented in that

CLASSIFICATION RATEMAKING

paper follows the $n/(n+K)$ formula shown above, but corrected for bias. The resulting formula, however, will always result in credibility less than 1. The section of this examination dealing with trend contains additional discussion of various alternative credibility formulas. Included there are discussions of the classical credibility, the Bühlmann, and Bayesian approaches.

Our tests of alternatives to the current NCCI formulas did not include a specific test for the ratio formula. Reasons for this decision were primarily practical, though one reason does address consistency in methodology. We note, however, that this decision should not be interpreted as a judgement that the use of a ratio formula is inappropriate in classification ratemaking methodology.

One set of reasons stem from practical considerations. In addition to the question of selecting the constant K are practical considerations of the time and expense involved in calculating and testing additional alternatives. As can be seen from the above graphs, the two families of credibilities tend to have similar characteristics, with the exception that the ratio method does not allow for classes to be fully credible. As we will discuss more below, we included tests of the power method using exponents both above and below the current $2/3$ power used by NCCI. Since shapes of the various credibility curves tend to be similar we believe that this "bracketing" will provide similar indications to those of the ratio method.

As for the consistency reason, the current methodology generally assumes that a state's experience, at a certain volume, is fully credible. This assumption is implicit in the calculation of the industry group differentials. It appears then, that the use of the ratio formula with the current NCCI methodology would give inconsistent treatment to the same volume of experience at two different points. Specifically, through use of a ratio formula, a volume of experience could be fully credible at the industry group level but only partially credible at the individual class level.

The third characteristic of the classical formula for credibility is volume. NCCI uses the level of expected losses in a class as the measure of volume from which to calculate the credibility of the indicated pure premiums. In addition, NCCI uses claim counts to calculate the credibility of the pure premiums indicated by national relativities.

These represent two of the volume measures that have been used in this credibility formula. The approach in the Longley-Cook article looks at the variability in average cost per claim. Since the standard deviation is inversely proportional to the square root of the

CLASSIFICATION RATEMAKING

sample size, that article uses the number of claims as the credibility base. This credibility base is widely used in property and casualty ratemaking.

If we were to assume that all classes experience the same frequency of claims then the only difference between classes would be in the average cost per claim. We would then be concerned with how well the sample mean, represented by experience, approximates the true underlying expected average cost for the class. This then would suggest using claim counts as a credibility base.

However, if frequency varied from class to class then using claims as a credibility base would give less credibility to the experience of a large, low frequency class and more credibility to a possibly smaller, higher frequency class. The use of expected losses as a credibility base, as is currently the NCCI's practice for indicated pure premiums, overcomes this specific problem.

On the other hand, using expected losses as a credibility base causes a similar difficulty to arise at another place. Consider two classes of the same size, with one having higher expected losses than the other simply because it is a higher loss class. Then the indicated pure premium of the higher loss class would be assigned a greater credibility by this method than would the lower loss class.

In recognition of the above discussion we considered several specific alternatives to the credibility formulas used in classification ratemaking. As mentioned above, we did not consider ratio formulas since they were inconsistent with assumptions in the overall ratemaking approach. We thus concentrated on alternatives that followed the classical credibility approach.

From this review of credibility concepts, we explored the following specific alternatives to these credibility formulas:

- a. We replaced the current credibility formula:

$$Z = (\text{Volume/Full Credibility})^{2/3}$$

with the formula:

$$Z = (\text{Volume/Full Credibility})^{1/2}$$

CLASSIFICATION RATEMAKING

for the both indicated partial pure premiums and the partial pure premiums indicated by national relativities. In both cases we retained the full credibility standard used in the current NCCI formula. This corresponds to the more usual square root credibility formula discussed above. It increases the credibility of classes which are not fully credible relative to the current formula.

b. To test the sensitivity of the credibility formula to the full credibility standard we retained the current basic credibility formula but we used a full credibility standard that was double the current NCCI standard. This will reduce the number of fully credible classes and assign lower credibility in most cases compared with the current formula.

c. We replaced the current credibility formula:

$$Z = (\text{Volume/Full Credibility})^{2/3}$$

with the formula:

$$Z = (\text{Volume/Full Credibility})^{0.8}$$

for both indicated partial pure premiums and partial pure premiums indicated by national relativities. In both cases we retained the full credibility standard used in the current NCCI formula. This is intended to provide a "bracket" test of the current 2/3 factor and decreases the credibility assigned to any class which is not fully credible under the current standard while maintaining the current full credibility standard.

d. We replaced the expected loss credibility base by a payroll base for indicated pure premiums using this formula:

$$Z = (\text{Payroll/Full Credibility})^{1/2}$$

and for partial pure premiums indicated by national relativities:

$$Z = (\text{Number of Claims/Full Credibility})^{1/2}$$

For pure premiums indicated by national relativities, we retained the current NCCI full credibility standard. For state indicated pure premiums, we modified the full credibility standard to approximate the average amount of payroll necessary to achieve the current full credibility standard in terms of expected losses. The use of payroll as a volume measure

CLASSIFICATION RATEMAKING

increases the credibility for not fully credible classes with lower than average pure premiums and tends to decrease the credibility for classes with higher than average pure premiums.

e. For indicated partial pure premiums:

$$Z = (\text{Number of Claims/Full Credibility})^{1/2}$$

and for partial pure premiums indicated by national relativities:

$$Z = (\text{Number of Claims/Full Credibility})^{1/2}$$

In both cases, we used the full credibility standard that the NCCI currently uses for pure premiums indicated by national relativities. This was selected to test the current claim count based credibility approach used for other lines of insurance and reduces the credibility of low frequency, high severity classes.

A more complete discussion of these conclusions appears in part IV of this section of this examination report.

B. Experience Period

NCCI uses three years of experience to determine both the indicated partial pure premiums and the partial pure premiums indicated by national relativities. We explored the effect of increasing the experience period used in calculating indicated pure premiums to four or five years. In both cases we retained the partial pure premiums indicated by national relativities used in the current NCCI methodology.

C. Loss Limitations

The current NCCI classification ratemaking methodology calculates the indicated pure premiums for a class based on limited losses. The use of a loss limitation in property and casualty ratemaking is not uncommon. The intent of such limitation is to avoid destabilizing the rates for a small group of insureds due to the occurrence of a random large claim. The current NCCI approach attempts to distribute losses in excess of the per claim and per

CLASSIFICATION RATEMAKING

occurrence limitations uniformly to all classes within each industry group, through the test correction factor process.

The level of losses included in calculating the indicated pure premiums may affect the rates given to individual classes. The lower the loss limitation, the more losses are pooled within the industry group. Conversely, the higher the loss limitation, the greater the chance that a few large claims could influence the rates for a class and add unnecessarily to the volatility of class rates over time.

We considered specific alternatives to the loss limitations in the current NCCI procedure as follows:

- a. Losses limited to one-half of the current loss limitation,
- b. Losses unlimited, and
- c. Loss limitations varying between a. and b. above based on class size. The limitation in this case is described by the following formula:

$$\text{Limitation} = \frac{\text{Current}}{2(1 - \text{Credibility})}$$

"Current" refers to the loss limitation the NCCI currently uses for the class and credibility refers to the current smallest class partial pure premium credibility used by NCCI. In the case of a class of sufficient size for the credibility to be one, we use unlimited losses.

A more complete discussion of these conclusions appear in part IV of this section of this examination report.

Comments on the treatment of excess losses are included in Sub-Section III.1 below.

CLASSIFICATION RATEMAKING

D. Analysis of Industry Group Relativity Procedure

The current NCCI methodology uses three years of experience in calculating industry group relativities. We explored the effect of changing this exposure base to either four or five years.

E. Analysis of Trend Factor Application

The current NCCI methodology adjusts the indicated pure premiums to reflect the growth in loss costs per unit of exposure between the experience period used in the ratemaking methodology and the time for which the rates are applicable. In the current classification ratemaking methodology a single factor is used to adjust all indemnity losses, independent of the policy year. A separate factor is used to adjust medical losses.

If trend is positive, this procedure will overstate the estimated losses at future cost levels from later policy years and understate those estimates from earlier policy years. This will show significant systematic effect only on classes that experience significant change in volume over the experience period. We have tested the significance of this potential inconsistency as part of this examination.

F. Alternative to Pure Premiums Based on National Relativities

The pure premium indicated by national relativity is the third component of the pure premium derived by formula. We recognize that there has been a recent change in the calculation of these pure premiums. The original method was discovered to cause the pure premium indicated by national relativity to be overstated in the case that a state had a class or classes not present in one or more other states.

The current NCCI methodology corrects for this by calculating the adjustment factor applied to losses in other states using only classes existing both in the state under consideration and in the other states. In addition, we understand that the revised NCCI method now balances pure premiums indicated by national relativities by industry group within a state.

Some discussions regarding the current classification ratemaking methodology raise concerns with the applicability of pure premiums indicated by national relativity to class pure

CLASSIFICATION RATEMAKING

premiums for a particular state. We recognize these concerns and developed an alternative that keeps the current methodology but introduces a regional component to the pure premiums determined by national relativities.

This alternative calculates two separate sets of partial pure premiums and combines the two to replace the current pure premiums indicated by national relativity. The first set is simply the current pure premiums indicated by national relativity in the current ratemaking methodology.

The second set is calculated in a similar manner but includes only the states in the same NCCI region as the target state. The pure premiums indicated by national relativity are then replaced in the credibility weighted average of these two indications. The weight given to the regional partial pure premium is calculated using the same formula as used for pure premiums indicated by national relativity.

G. 'F' Classification

In the course of our examination several questions were raised by the Examination Oversight Group regarding Federal or 'F' classifications that are discussed in detail in Appendix D. As noted there, the current NCCI 'F' class methodology does not incorporate trend.

H. Segregation of Class in "All Other" Industry Group

Current ratemaking procedures stratify occupational classes into two specific industry groups (i.e. "Manufacturing" and "Contracting") and one miscellaneous category (i.e. "All Other"). We understand the original motivation for creating the two specific groups was to combine similar types of work activity for ratemaking purposes. Theoretically, the result of this stratification is increased homogeneity of risks within the ratemaking categories.

Given the current size of the "All Other" group and the diversity of classes within that group, the EOG requested that we analyze the feasibility and desirability of further stratification at this time. This is a particularly significant issue in light of the apparent transition to a service oriented economy in a number of jurisdictions. In this situation, the

CLASSIFICATION RATEMAKING

"All Other" group can include a wide variety of occupational activities ranging from heavy industrial to purely clerical.

This issue is discussed in section VII.

I. Other Areas

In the course of our examination, we identified the following additional areas that warrant additional comments:

1. An apparent inconsistency of loss limits used in the various components of the partial pure premiums
2. Losses in excess of limitation
3. Weighting used in calculating test correction factors
4. Development of losses incorporated in classification ratemaking
5. Volatility in classification rates arising from that in national experience
6. Swing limits

These are discussed below.

1. An apparent inconsistency of loss limits used in the various components of the partial pure premiums

The current NCCI methodology uses the weighted average of three pure premium components in determining the relative cost differences among the classes. One characteristic of this methodology is that if one of these three components is either inherently higher or lower than the others then the relative loss costs among the classes will be influenced. This could result in rates for larger, fully credible classes being affected in one way and rates for smaller, non-fully credible classes being affected in another.

An example that we identified of such an inherent difference between components is in the use of loss limitations in the current procedure. The losses used in calculating the indicated

CLASSIFICATION RATEMAKING

partial pure premiums and the partial pure premiums indicated by national relativities are both limited. On the other hand, the current on-level partial pure premiums appear to be calculated without loss limitation at the specific class level. The current NCCI procedure does provide for the distribution of industry group losses in excess of the limit among the classes comprising the group in each state.

Thus, in general, the partial pure premium derived by formula for fully credible classes is based completely on limited data. On the other hand, the partial pure premium for non-fully credible classes includes weight to the current on-level partial pure premiums which include a loading for large claims. The result is higher pure premiums derived by formula than would have resulted had the current on-level partial pure premiums been limited. Thus, final rates for fully credible classes are lower and final rates for non-fully credible classes are higher than would be the case if the current on-level partial pure premiums were limited. We do note that in both cases, the same overall average industry group and statewide rates are developed.

An example, though extreme, may help illustrate this concept. Suppose we have only two classes, 1 and 2, with the following pure premium components and corresponding credibilities. We limit ourselves to a single pure premium component to keep the calculations simple.

<u>Class</u>	<u>Indicated Pure Premium</u>	<u>Current On-Level Pure Premium</u>	<u>Pure Premium Indicated by National Relativities</u>	<u>Credibility for Indicated Pure Premium</u>	<u>Credibility for Pure Premium Indicated by National Relativities</u>	<u>Pure Premium Derived by Formula</u>
1	1.00	2.00	1.00	100%	0%	1.00
2	1.00	2.00	1.00	50%	25%	1.25

Both classes have the same pure premium components. The only difference is the credibility assigned to those components. Class 1 is a larger, fully credible, class while class 2 is smaller and not fully credible. The inherent difference between the example indicated pure premiums and the example present on-level pure premiums causes the final pure premium derived by formula for class 1 to be smaller than that for class 2, even though none of the pure premium components show any difference.

CLASSIFICATION RATEMAKING

This highlights a general characteristic of the current NCCI methodology. If the indicated pure premium is inherently lower than at least one of the other two components in the pure premiums derived by formula, then rates for fully credible classes tend to be understated while those for non-fully credible classes will tend to be overstated. Conversely, if the indicated pure premium is inherently higher than at least one of the other two components of the pure premium, then rates for fully credible classes will tend to be overstated while those for non-fully credible classes will tend to be understated. Thus it is important in the current procedure to assure that none of the three components is inherently larger or smaller than the others.

In summary, even if relative loss costs among classes within each of the three components is the same, relative differences between the components could influence the final rates for individual classes in the current NCCI classification methodology. We recommend that the NCCI consider alternatives to the current method that are not as sensitive to inconsistencies among the data elements.

One such alternative would be to use relativities to overall average partial pure premiums instead of the actual pure premiums when determining the pure premium derived by formula. For example, the medical indicated partial pure premium relativity for a class would be the medical indicated partial pure premium divided by the weighted average of all medical indicated partial pure premiums, using experience period payrolls as weights. Similarly, the medical current on-level partial pure premium relativity for a class would be the medical current on-level partial pure premium divided by the weighted average of all medical indicated partial pure premiums, using the same experience period payrolls as weights. This overcomes the inherent inconsistencies since the relativities, as opposed to the partial pure premiums themselves, should balance to unity in each component separately.

2. Losses in Excess of Limitations

The current NCCI methodology attempts to distribute losses in excess of the per claim and per occurrence limitations uniformly to all classes within industry group as included in the test correction factors. Methodologies often used in liability ratemaking correspond to the current NCCI approach in that losses above a certain limit are usually accounted for uniformly among classes. In fact, in many cases, the losses in excess of the limit are estimated using nationwide data.

CLASSIFICATION RATEMAKING

In addition, the loss limit used in overall rate calculations for those coverages is sufficiently low to result in a reasonably high probability that losses will exceed the limit. The practical need to calculate rates for coverage in any class at any loss limitation also requires separation of class ratemaking from increased limits ratemaking. Thus, the assumption is that excess losses are fortuitous and not directly related to class, and in many cases, geographical characteristics.

Any insurance classification and ratemaking methodology must strike a balance between the pooling of loss central to insurance and the responsiveness of rates to class differences. The liability approach to increased limits ratemaking inherently opts for pooling of losses above the loss limitation among the classes.

One alternative that has been suggested involves including a provision for claims in excess of the loss limitation in a class using a much larger number of years of experience in that class. This is similar to the procedure used in calculating catastrophe loads in property insurance, though the catastrophe loads are usually not calculated or applied at the class level.

There are several practical problems with this approach. Probably the most significant is that it assumes that the loss limitation will be consistent over a number of years. As with credibility concerns, the number of years required to obtain a reasonable estimate of the excess loss potential of a class will vary from class to class, with a significant number of years needed for the smaller classes.

Over such a time period, characteristics of the individual classes can change significantly. For example, without adjustment, a class could be penalized for many years for safety problems that have long since been remedied. Adjustments for such changes may be difficult but may be possible. More difficult, however, would be recognition of more subtle changes. As a result of these theoretical concerns and practical limitations, we did not specifically test this alternative.

This aspect of the current procedure was not anticipated in our original proposal for this examination or in our original data requests. We have, however, performed a limited test of the significance of differences in excess losses that may exist among classes. These are discussed in Section IX.

CLASSIFICATION RATEMAKING

3. Weighting Used in Calculating Test Correction Factors

One of the purposes of the test correction factor used in the current NCCI methodology is to ensure that the combined effect of rate changes by class equals the indicated overall rate change. Under current procedures, this balance is achieved using the distribution of exposures by class in the WCSP data used for classification ratemaking (i.e., the latest available three years). Ideally, the balance should be achieved using the distribution of exposures by class inherent in the Financial Call data used to develop the overall indication; however, exposures by class are not available in the Financial Call data.

The class distribution inherent in the Financial Call data would be better approximated by the latest available single year of WCSP exposure data. Using the latest year would be one year more current than the midpoint of the three year period currently used, and two years more current if the experience period were expanded to five years.

The impact of such a change on final rates is a function of the extent to which the exposure distribution is changing and the variation of rate changes by class. It is thus difficult to quantify at this time. It is likely that the difference would frequently be insignificant. However, we identified a number of states with rapidly changing class distributions, as described in this examination report in Volume V, Section IIB - Part 3; the section dealing with the analysis of trend. Thus, this change may have a significant impact in some cases. In any case, a change to using a single year of exposure data would probably be relatively easy to implement in the calculation of the test correction factor. In addition, it would generally provide a better match between the distribution of classes inherent in the overall rate level change indication and the distribution used in balancing the change for the individual classes.

4. Development of Losses

The Examination Oversight Group expressed concerns regarding the development of losses used in classification ratemaking. Though this area of exploration was not contemplated within the original scope of this project, we recognize the potential significance of this aspect of the methodology. We believe that the analytic tools we developed for this analysis can be used by NCCI to analyze the relative accuracy and consistency of specific alternatives to the current development methodology.

Two alternatives to the current approach have been mentioned in this regard. The first would use an additive component of expected future losses in place of the multiplicative

CLASSIFICATION RATEMAKING

development currently used. This is similar to the Bornhuetter-Ferguson approach. The second alternative would base the classification indication on a comparison of losses reported to date with the expected losses emerged to date. The expected emerged losses in turn would be determined using historical development and the expected losses underlying current rates. We caution that the consistency concepts discussed on pages 26 through 28 be recognized in the construction of any specific alternative in this area.

5. National Experience

In the course of our examination, the Examination Oversight Group expressed concerns regarding the impact of nationwide data in the current methodology. We also recognized this in our test of a regional alternative as discussed on pages 71 and 72. Limitations in available data limited our consideration to the use of only three years of data in calculating partial pure premiums indicated by national relativities used in this analysis. Other than the comments here, and our analysis of a single regional alternative, we have not explored this issue further in this examination.

It is possible that other approaches to incorporating national experience may be beneficial. One such alternative that was suggested is a stepped approach. This approach is similar to that used for statewide data in classification ratemaking for California workers compensation. This would use fewer years of national experience for large classes with increasing years used for smaller classes. Once again, NCCI could use the analytic methods we developed for this examination to evaluate alternatives in this area. Again, we caution that specific alternatives be reviewed in light of the consistency discussion in pages 26 through 28 of this part of this examination report.

6. Swing Limits

The request for proposal did not request any study of the use of swing limits by NCCI, and none was performed in this examination. Swing limits are limitations of the amount of change for specific classes. We understand that the reason for this omission in the request for proposal was that the participating states felt that swing limits are often used to overcome limitations in classification ratemaking methodology. Although, another view is that they are used to maintain price stability in the process. Instead of addressing swing limits as such, the request for proposal directed that significant resources be applied in researching credibilities, loss limitations and whether accuracy would be improved by using more years of data. It is likely that improvements in these areas could have the potential of significantly reducing the impact of swing limits.

CLASSIFICATION RATEMAKING

CLASSIFICATION RATEMAKING

IV. EVALUATION OF CREDIBILITY FORMULA, EXPERIENCE PERIOD AND LOSS LIMITATION (Objective 4a)

In our review of specific alternatives, our first step was a review of the current approach used by the NCCI in determining class rates. This review was for the purpose of understanding the overall framework used by the NCCI, rather than exhaustive research regarding its application in each of the states in which the NCCI prepares filings.

We focused our analysis on the methodology for the classes considered by NCCI as having sufficient credible experience, i.e., the "reviewed classes." The methodology used for the other smaller, or "non-reviewed," classes and unique methodology used for special classifications were not analyzed by procedures described in this section.

The discussion in part III above identifies specific alternatives to NCCI procedures. As can be recognized from the description of current classification ratemaking methodology in Section IIA of our ratemaking report, that methodology is complex with many adjustments made to the data in the process. The interactions of various aspects of that methodology make a general theoretical review of particular aspects subject to the real possibility of missing significant interactions.

For this reason we selected an empirical approach to testing the impact of the various alternatives. For each alternative identified, we compared rates under both the current methodology and under the alternative methodology for selected states and, in most cases, for multiple rate filings.

In this review we intentionally selected alternative approaches that changed one aspect of the current ratemaking methodology at a time. For example, when considering the effects of changing the number of years used in the current methodology from three to, say, five, we left all other aspects of that methodology unchanged. Similarly, when we tested alternatives to the current credibility formula we used only three years of data, and so forth. In this way we could isolate the specific impact of each alternative considered.

We note that the various characteristics tested are not independent. As indicated earlier in this section of this examination report, we recommend that NCCI increase the experience period from three to at least five years unless subsequent tests noticeably differ from those presented in this report. It is thus likely that the effect of an alternative credibility formula or loss limitation applied to five years of data will differ from that of the same alternative used with three years of data.

CLASSIFICATION RATEMAKING

A. Data

The data for this portion of our analysis was several final rate calculations produced by NCCI. We requested that NCCI prepare rate estimates using its current methodology and the various specific alternatives, for various states and policy years. We did not independently audit the calculations of the NCCI in these tabulations.

Our requests to NCCI in this regard contained quite detailed and explicit instructions for NCCI to modify their current methodology to reflect the changes we wanted incorporated. Appendix A to this section of this examination report contains the correspondence. In addition to these letters, we discussed our requests with NCCI personnel to assure ourselves that they understood our requirements.

Though we did not perform a separate audit of those data, we did review the results for consistency and reasonableness. This review led to questions to NCCI and, in at least one instance, the re-calculation of rates for an alternative.

B. General Methodology

We believe the most important tests we were able to perform were comparisons of actual limited loss experience with that expected from each alternative. These tests were applied to all classes combined and to classes of various sizes. In addition, we developed tests to compare the consistency of various alternatives in identifying relative cost differences over time.

We selected tests against limited rather than unlimited losses because of the assumptions underlying the overall classification ratemaking approach. Losses are limited in the calculation of class rates to dampen the effect of a few large claims on the rates for individual classes. It is the intent of the current approach to spread the losses above these limits in each industry group among all classes in that group. We thus believe that it is more appropriate to test how well the classification ratemaking methodology or an alternative predicts the limited losses.

Since our analysis was concerned with how well the various methodologies performed in identifying relative loss differences among the classes, we compared the actual 1987 losses at first report with expected losses by class predicted according to each methodology,

CLASSIFICATION RATEMAKING

normalized to add to the total actual losses. We recognize potential limitations in relying solely on first report data. More mature data was not available to compare with all alternatives we considered.

The expected losses by class were calculated as the product of the payroll, manual rate calculated using a given methodology, and actual ratio of earned to manual premiums for the class, and then uniformly adjusted to total the same as the total reported losses for the year. That is, the expected loss for class i , state j and alternative rate calculation k , E_{ij}^k was calculated as:

$$E_{ij}^k = \frac{P_{ij} \times R_{ij}^k \times \frac{EP_{ij}}{MP_{ij}}}{\left[\frac{\sum_i P_{ij} \times R_{ij}^k \times \frac{EP_{ij}}{MP_{ij}}}{\sum_i L_{ij}} \right]}$$

Where P_{ij} denotes the payroll for class i , R_{ij}^k the rate for class i in state j calculated using the method k , MP_{ij} denotes the 1987 manual premiums for class i in state j ,

EP_{ij} denotes the actual 1987 earned premiums for class i in state j , and L_{ij} denotes the 1987 losses for class i in state j at first report, limited in the same manner that the losses are limited in the calculation of the indicated pure premiums and t runs over all classes.

We applied two statistical tests to identify which of two alternatives gave a more accurate estimate of the relative loss costs. One test uses the Wilcoxon signed rank test to measure the significance of differences in accuracy in forecasts for the various classes. The other test, termed the underwriting test, considers the combined relative accuracy for certain groups of classes.

CLASSIFICATION RATEMAKING

1. Wilcoxon Test on Accuracy

The Wilcoxon signed rank test is a fairly well known non-parametric statistical test to compare the equality of two distributions given samples from each. Its choice in this situation is primarily motivated by the lack of any clear choice of the statistical model for the distributions of the squared errors and by the lack of independence between the alternatives tested.

This statistic considers the square of the error resulting from the forecast. For each class i and state j , we define the square error for method k , SE_{ij}^k , as

$$SE_{ij}^k = E_{ij}^k \left[\frac{L_{ij}}{E_{ij}^k} - 1 \right]^2 = \frac{(L_{ij} - E_{ij}^k)^2}{E_{ij}^k}$$

The first part of this equation shows that the SE_{ij}^k is the square of the relative error

between the actual losses L_{ij} and the expected losses E_{ij}^k , weighted by the volume of expected losses. The second part simply rearranges and cancels terms. This latter term may be familiar to the reader as similar to terms in the chi-squared statistic sometimes used to test the goodness of fit for probability distributions.

Since the various alternate ratemaking methods are not independent and are based on the same data, and since the square errors do not necessarily follow a normal distribution, we selected the Wilcoxon signed rank statistical test to test whether the two methods are significantly different in forecasting the ultimate losses. For this, we define the intermediate statistic for each class i in state j , D_{ij}

$$D_{ij} = \text{Rank}(|SE_{ij}^1 - SE_{ij}^2|) \times \text{Sign}(SE_{ij}^1 - SE_{ij}^2)$$

CLASSIFICATION RATEMAKING

Here, Rank denotes the rank of the quantity in parenthesis when the quantities are listed in order, smallest to largest, and Sign denotes the sign of the quantity in parenthesis. The Wilcoxon Statistic related to these quantities is

$$W_j = \frac{\sum_{i=1}^n D_{ij}}{\sqrt{n(n+1)(2n+1)/6}}$$

where n is the number of classes. If $E[SE_{ij}^1] = E[SE_{ij}^2]$, then for large values of n , W_j has an approximate standard normal distribution. The hypothesis that alternative 2 is more accurate than alternative 1 (i.e. significantly lower differences between predicted and actual) can be accepted with confidence "p" if W_j is greater than the value shown in the table below:

Critical Values

<u>p</u>	<u>W_j Greater than</u>
90%	1.282
95%	1.645
99%	2.326

Source: Standard Normal Table

Since classification alternatives may affect different sized classes differently, we separately applied the Wilcoxon test to three groups of classes in each state; large, intermediate and small. To determine the size category for each class, we listed all classes in all states analyzed, ordered by premium volume. The label "large" was given to those classes, sorted in this manner, that comprised the first one-third of total premiums. The next one-third of total premium arises from the "intermediate" classes while we used "small" to denote the remaining classes. A class could be considered large in one state and small in another if

CLASSIFICATION RATEMAKING

the premium volume for that class in the two states is different. One state could have many large classes while another has few, or even none.

While other groupings are possible, the procedure is objective and consistent. The specific results obtained, of course, are influenced by these definitions but we recognized this in formulating the conclusions and recommendations for this section.

2. Underwriting Test

Another test that has been applied to identify differences in forecasts between classification rate methodologies has been termed an underwriting test (see the paper by G. Meyers referenced in Section III above).

For this test, the classes are divided into two groups: group 1 having classes with expected losses for the current method less than those for the alternate method being tested, and; group 2 all others. By construction, the ratios of actual to expected losses will be lower for the alternative method than for the current method in the first group and higher in the second.

If, however, one method produces ratios of actual to expected losses that are closer to 1.00 in both groups than the other, then that method can be considered to provide a better indication of the relative loss cost differences among classes. In such a case, the method with ratios closer to 1.00 would provide coverage to better classes for lower rates and worse classes for higher rates than the alternative, thus giving it a competitive advantage in the marketplace. This is the origin of the name for this test, the underwriting test.

The significance of the differences in underwriting ratios is tested by comparing ratios of actual to expected losses from similarly sized groups randomly selected from all groups using the "bootstrapping" technique. The bootstrapping approach is sometimes used in statistical analysis when the actual underlying distributions are either unknown or are too complex to analyze directly. The above-cited paper by G. Meyers contains a more complete description of this approach.

3. Consistency Test

Accuracy in forecasting relative cost differences is only one aspect of a good classification ratemaking methodology. Rate relativities should be consistent over time. We would have preferred to compare methods over many years. However, due to limitations in the

CLASSIFICATION RATEMAKING

number of years of data available, a more extensive test of this criterion was not possible for this report.

Any ratemaking methodology must balance stability and responsiveness. In order for insurance to be valuable to the consumer there should be some predictability in prices from one year to the next; prices should not increase substantially one year only to drop substantially the next. On the other hand, the price of insurance should respond to changes in the cost to provide that insurance. If the price is too slow to respond to changes the consumer could also lose, either by paying too high a price for the coverage or in buying coverage at too low a price from an insurer that subsequently cannot meet its obligations.

We thus devised another comparison of the current approach with alternatives that we term the consistency test. The goal of this test is to see how consistently a particular methodology identifies "good" or "bad" classes. Broadly, the concept compares the rate for a class in a state with the rate for that same class based on a broader cross-section of states, after adjustment to the target state's cost levels.

A desirable characteristic of a classification methodology is to consistently identify classes in individual states as better or worse than the broader average. Conversely, it is undesirable for a method to identify a class as much better than average one year and much worse the next. Such a methodology would result in an unnecessarily unstable rate for that individual class.

For this analysis, we define consistency as the ability of a classification methodology to consistently identify classes in individual states as better or worse than an average rate. We tested whether a method would identify a class as much better than average one year and much worse the next. Such a methodology would result in an unstable rate for that individual class.

We borrowed some of the concepts behind the pure premiums indicated by national relativities in constructing our average rate. Our consistency test for classes in a state begins with the average rates for those classes based on the experience of other states, adjusted to the target state's loss levels. We then compare the rates for the classes in the target state with the averages. If, over several policy years, this comparison shows wide fluctuations, that is, if a particular methodology identifies a class in a state as much better than average one year and much worse the next, we would conclude that methodology tended to result

CLASSIFICATION RATEMAKING

in inconsistent indications. If there were little fluctuations in the comparison, we would conclude that the method produced consistent indications.

We thus define the "consistency ratio" for class i in state j for classification ratemaking methodology k as:

$$C_{ij}^k = \frac{R_{ij}^k}{N_{ij}^k}$$

where R_{ij}^k represents the rate calculated by method k for class i in state j and N_{ij}^k represents the average for other states, adjusted to the same overall average as state j .

We calculate the N_{ij}^k values in three steps. To calculate N_{ij}^k for state 1, that is for $j=1$ we calculate the average rate over all classes, using the payroll in state 1 as weights:

$$A_j^k = \frac{\sum_{i \in I_j} P_{ij} R_{ij}^k}{\sum_{i \in I_j} P_{ij}}$$

for each state $j=2, 3, 4, \dots$, where I_j denotes the set of classes with payroll in both states 1 and j . We next calculate a similar average for the target state,

CLASSIFICATION RATEMAKING

$$B_j^{kl} = \frac{\sum_{i \in I_{ij}} P_{il} R_{ij}^k}{\sum_{i \in I_{ij}} P_{il}}$$

The value of N_{ij}^k is then calculated as the weighted average of the rates for class i in state j ($j = 2, 3, \dots$) and method k using the premiums in the various states as weights:

$$N_{il}^k = \frac{\sum_{j=2}^m P_{ij} \times R_{ik}^k \times \frac{B_j^{kl}}{A_j^k}}{\sum_{j=2}^m P_{ij}}$$

Similar calculations would follow for the remaining states. In those situations, however, the summations over j would run from 1 through m (the number of states) and exclude the target state. In these calculations "other" states represent all other states for which the alternate calculations were performed. This is not the same as what the NCCI would refer to as nationwide.

We then analyzed the variance of the "consistency ratios" for each class over time and used the Wilcoxon Statistic to test the significance of the difference between the consistency of the current and alternate methods.

Although the Wilcoxon Statistic is calculated using the same information as the average variance in the consistency test, it gives different weights to the various observations. In particular, large "outliers" have a more significant affect on the average variance than on the Wilcoxon Statistic. Thus, it is possible for a raw comparison of the average variance to provide one indication and the Wilcoxon Statistic to provide another, as happened when comparing the current credibility formula with the use of 0.5 power. The Wilcoxon test permits us to identify statistically significant differences whereas the raw comparison does not.

CLASSIFICATION RATEMAKING

4. Degree of Impact

Up to this point, the tests we described were focused on one of two basic areas, accuracy and consistency. In each case the focus was a comparison of the current approach with a single alternative. There was no comparison of the degree of impact that one alternative may have relative to another.

We therefore formulated an index to quantify the impact of a particular change and to compare with the impact of other changes. Rather than testing whether an alternative is "better" or "worse" as compared with the current procedure, this index is designed to tell whether one alternative produces "more" change from the current approach than another.

The index Q_j , referred to later as the "square difference index," for state j is calculated as:

CLASSIFICATION RATEMAKING

$$\begin{aligned}
 Q_j &= 100 \times \frac{\sum_{i=1}^n P_{ij} (R_{ij}^1 - R_{ij}^2)^2}{\sum_{i=1}^n P_{ij}} \\
 &= 100 \times \frac{\sum_{i=1}^n P_{ij} R_{ij}^1}{\sum_{i=1}^n P_{ij}} \\
 &= 100 \times \frac{\sum_{i=1}^n P_{ij} (R_{ij}^1 - R_{ij}^2)^2}{\sum_{i=1}^n P_{ij} R_{ij}^1} \\
 &= 100 \times \frac{\sum_{i=1}^n P_{ij} \times R_{ij}^1 \times \frac{(R_{ij}^1 - R_{ij}^2)^2}{R_{ij}^1}}{\sum_{i=1}^n P_{ij} R_{ij}^1}
 \end{aligned}$$

The first of the three equations shows the origin of Q_j . The numerator of the large fraction is the weighted average of the square of the differences between the rates of the two methods using the payrolls in state j as the weights. The difficulty of this measure in comparing states is that states with different average rates would be expected to have different average square differences due only to the differences in the overall average rates.

We thus normalize Q_j by dividing it by the state j average rate under the current methodology. The multiplication by 100 expresses the resulting ratio as a percent.

The second of the two equations is an easier way of calculating the index and follows from the first since the denominators of the two fractions cancel. The third equation is shown to

CLASSIFICATION RATEMAKING

link Q_j with the SE_{ij}^k terms discussed above in relation to the Wilcoxon test. The ratio in the sum of the numerator is in the same form as SE_{ij}^k (page 36) if we replace the actual losses L_{ij}^k by the rate R_{ij}^2 and the expected losses E_{ij}^k by the rate R_{ij}^1 . As noted above, this is a term in the chi-squared statistic often used for statistical tests. The last equation shows that Q_j is a weighted average of these relative square differences, using the total premium by class as weights.

Comparison of these ratios for two alternatives in the same, or even different, states indicates which of the alternatives results in more change from the current procedure. The larger the value of Q_j , the more classes and premium volume would change due to the alternative.

5. Charts

The Q_j statistic does not provide any information as to which alternative is more accurate or more consistent. This statistic also does not indicate how many classes are affected by an alternative or which are affected more. In order to provide more insight to the answers of these questions we have prepared a series of graphs, one for each pair of alternatives for which calculations were provided by NCCI. These are contained in Appendix F to this section.

The charts show the number of classes plotted by percentage impact and summarize the information developed from the tests described above for each alternative compared to the current NCCI procedure.

Each chart is composed of a bar graph and a line graph. In all cases the horizontal or x-axis indicates the size of the difference calculated as:

CLASSIFICATION RATEMAKING

$$\frac{R_{ij}^2 - R_{ij}^1}{R_{ij}^1}$$

The bars and the left axis of the charts represent the number of classes whose differences are in the indicated range. For example, for Colorado, comparing the change between the current classification methodology and one which uses five years of experience in calculating 1987 rates, we see there are 135 classes for which the change is less than 1%, there are 73 classes whose rates would decrease between 1% and 3%, 56 classes whose rates will increase between 1% and 3%, and so forth.

The line graph on the same chart represents the total premium, calculated as 1987 rate times the payrolls for policies written from March, 1984 through February, 1985. This was the most recent WCSP data available for the analysis of the 1987 rates. The amounts are shown in millions on the scale at the right of the chart. Thus, the classes that experienced less than 1% change between the two methods had a total of \$45 million in premiums. This is compared with \$63 million for classes experiencing a decrease of between 1% and 3% and \$46 million for classes having increases of between 1% and 3%, and so forth.

This particular chart shows that the largest volume of premium arises from classes for whom the alternate methodology provides lower rates, with some high volume classes experiencing decreases of between 5% and 9%. This latter observation follows from the high values of the line graphs over this range and the relatively low count of classes affected. On the other hand, even though many classes experience changes of less than 1%, the premium volume for these classes tends, on the average, to be smaller.

Also shown on the chart is the value of Q_j , labelled as the "square difference index." In this case the index is almost 13, that is, the weighted average square difference between methods is almost 13% of the overall average state pure premium.

Each graph includes the Wilcoxon Statistic used to test the significance of the difference between methodologies on a class-by-class basis. We also included approximate normal values corresponding to the calculated Wilcoxon Statistic. These probabilities represent the approximate probability, under the assumption that the two alternatives are not different, that the Wilcoxon Statistic will not exceed the indicated value. Thus probability values near either 0 or 1 indicate significant differences between the two alternatives.

CLASSIFICATION RATEMAKING

C. Credibility Methodology

We requested that NCCI calculate alternate rate revisions, all using three years of data for classification ratemaking, with alternate credibility formulas described in Part III.A.

Alternate a - The first test maintained the current expected pure premium, and the current full credibility standard, but replaced the current $2/3$ power used by NCCI with the square root or $1/2$ power. We requested this test for Florida, Maine and Nebraska for 1987 through 1990 rates.

Alternate b - Partial credibility in the classical credibility pure premiums is also sensitive to the full credibility standard. We tested this sensitivity by requesting that NCCI calculate alternate rates using double the current full credibility standard, but leaving the power unchanged for 1987 through 1990 rates in Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon.

Alternate c - As shown in the first chart above, the use of the $1/2$ power gives more partial credibility than the current NCCI method at any level of expected losses. To bracket the results we also requested that NCCI calculate rates using the $4/5$ or 0.80 power. This request was for Florida and Maine for policy years 1987 through 1990.

Alternate d - As mentioned above, under suitable, rather general, assumptions, the standard deviation of the mean of a sample is inversely proportional to the square root of the sample size. If we consider the observed experience for a class as a sample, then a natural credibility base would be the number of exposures making up that sample. This credibility base overcomes the difficulties mentioned with both claims and expected losses as credibility bases.

To test the impact of this alternative, we asked that NCCI calculate 1987 through 1990 rates in Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon using the power formula with the square root of payroll as a credibility base for indicated pure premiums.

In this case, the state full credibility standard was calculated as twenty-five times the average statewide serious loss per dollar of statewide payroll for use with serious cases, and three hundred times the average non-serious or medical loss per dollar of statewide payroll

CLASSIFICATION RATEMAKING

for non-serious and medical pure premiums, respectively. For national relativities, the credibility was based on number of claims and used $p=1/2$.

Alternate e - To consider the number of claims as a credibility base, we asked NCCI to test the power formula using the square root of the number of claims reported. This request was for Florida and Maine for 1987 through 1990 rates. In this case we used the same full credibility standard as is currently used by the NCCI for credibility for pure premium indicated by national relativity. In particular we used a full credibility standard of twenty-five serious cases, three hundred non-serious cases and three hundred combined serious and non-serious cases for serious, non-serious and medical partial pure premiums, respectively.

D. Experience Period Methodology

By far the largest portion of the analysis for this section involved the effects of adding to the number of years used in classification ratemaking. The current methodology uses the three most recent available policy years of WCSP data for calculation of industry group differentials, indicated pure premiums and pure premiums indicated by national relativity.

Data availability limited the alternatives that we could explore. The most recent WCSP data available is generally for the 1987 policy year at first report. NCCI retains data for the most recent five filings, generally 1986 through 1990 at the time of this study.

The 1990 rates are based on policy years 1985 through 1987, the 1986 rates were based on 1981 through 1983 WCSP data, etc. Thus the earliest data we could be assured of was for 1981 policies. If we were to use four years of data, 1987 would be the earliest year for which we could be assured rates could be calculated. If we were to use five years of data, 1988 would be the earliest year. For some states, however, earlier data were available and NCCI was able to calculate alternate 1987 rates using five years of data. Thus, we restricted our accuracy tests to comparing with policy year 1987 experience.

Given these limitations, we did not believe we could effectively explore the effect of including more than five years of WCSP data in the classification ratemaking methodology. This is a practical limitation and should not be taken as a statement of the maximum number of years that we believe should be included in the methodology. However, we recognize that there may be a point where the age of data reduces its relevancy for

CLASSIFICATION RATEMAKING

estimating relative loss cost differences among classes. This latter consideration could be addressed by assigning declining weights by age of data.

We requested that NCCI calculate final rates using five years of WCSP data for the following twelve states: Colorado, Connecticut, Florida, Illinois, Louisiana, Maine, Michigan, Nebraska, North Carolina, Oregon, Wisconsin, and Utah. Although we obtained calculations for these twelve states, actual loss data corresponding to rates calculated using five years of data were only available for five; Colorado, Connecticut, Illinois, Maine, and Nebraska.

To test the sensitivity of incorporating four years, we also asked NCCI to perform the calculations using four years of WCSP data for Florida and Maine.

The number of years used affects many of the steps in the classification methodology. This is in contrast to other aspects reviewed here, for example the application of trend or credibility formula, that enter at limited points in the calculations.

We provided detailed instructions to NCCI staff for incorporation of additional years in the methodology. Appendix A to this section contains our letters to NCCI that detail the changes that we believed would need to be made to modify the current methodology.

We understand that NCCI followed their current methodology, with the changes detailed in Appendix A, to calculate alternative rates using four or five years of WCSP data. In the course of the analysis, however, practical considerations led to some changes in the methodology from that indicated in Appendix A.

Notably, WCSP data being available through fifth report, allowed the development to be calculated from the most recent report available to ultimate. This compares with the approximation in Appendix A assuming that only third report data were captured.

Another notable difference is in the calculation of the pure premiums indicated by national relativity. In discussions among project team members subsequent to our letter to NCCI, we believed a more balanced approach would be to have the pure premiums indicated by national relativities calculated using three years of data. This corresponds to a common practice in property and casualty ratemaking in using more experience at a finer level of detail and less experience at courser levels. This is also the case in the overall NCCI methodology where the indication from one policy year and one accident year are used to estimate the overall rate level change, but several years are used for estimating class rates.

CLASSIFICATION RATEMAKING

This modification also fits well with data availability from NCCI. The database that NCCI uses for the calculation of pure premiums indicated by national relativity maintains total summaries for three policy years and not individual policy year detail.

E. Loss Limitation Methodology

We asked NCCI to calculate 1987 through 1990 rates for Florida and Maine using unlimited losses. We asked NCCI to calculate 1987 through 1990 rates in Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon using half the current loss limitation and also the sliding scale loss limitation.

F. Conclusions

The exhibits in Appendix B to this section provide a complete summary of the results of these tests. There are four sets of exhibits contained in that appendix.

The first, Exhibit B-1, provides a summary of the square difference indices for all alternatives tested, sorted by state and policy year. These indices are measures of the overall difference between the current method and each specified alternative. As can be seen from the graphs in Appendix F to this section, the Wilcoxon Statistic in this case indicates that almost all of these differences are significant.

Exhibits B-2 and B-3 summarize the results of the accuracy and consistency tests, respectively. We have separate sorts, one showing all the alternatives tested within a single state and the other showing all states tested for each alternative.

Exhibit B-2 shows the indications of the underwriting test and the corresponding mean square errors for large, medium and small classes and for the entire state combined. The information provided for the underwriting test summarizes the number of classes that fall into each group, the actual and expected losses for each group and the resulting ratios of actual to expected losses by group.

The approximate significance (based on the boot-strapping approach) of difference in the loss ratios are also shown in that exhibit.

CLASSIFICATION RATEMAKING

The mean square error sections of these exhibits show the mean square error for the corresponding groups of classes for both the current and the alternative method. Also shown is the value of the Wilcoxon Statistic. We then used a normal approximation to estimate the significance level for that statistic where there were at least 10 classes. In cases where there were less than ten classes, we showed the exact probability calculation.

Exhibit B-3 summarizes the results of the consistency tests for the various alternatives. The first two pages of that exhibit show the results for all classes combined while the remaining pages show separate results for various sizes of classes within each state.

In all cases we show the weighted average variance of the ratios of the individual state's relative loss cost differentials by class to the relative loss cost differentials for all other states combined. A small variance would indicate that the corresponding method was consistent at identifying classes that are better or worse than the overall average.

Also shown are the Wilcoxon Statistics corresponding to the various alternatives. The statistics are calculated in such a way that a positive value indicates that the alternative method produced more consistent results than the current method and a negative value indicates the converse.

Also included in that exhibit are approximate probabilities that, under the hypothesis of no difference between the variances, a randomly selected random variable will exceed the given Wilcoxon Statistic. Values close to 0% indicate a high confidence that the alternative method is more consistent at identifying relative loss cost differences among classes than the current method. However, a value close to 100% indicates that the current method is more consistent.

In the remainder of this section, we discuss the results for the alternative tested, ranked generally in order of the significance of the results.

1. Experience Period -- Five Years of Data

Of the alternatives discussed in part III above, the use of five years of data in classification ratemaking appears to produce the largest differences from the current methodology. With the data available, five years appears to provide more accurate indications of actual differences in relative class loss costs. In every case tested, the mean square error of the relative loss costs using five years of experience was less than that using the current methodology. In every case the corresponding Wilcoxon Statistic was positive, again

CLASSIFICATION RATEMAKING

denoting a closer approximation using five years of data. The difference was significant at the 95% confidence level in one of the cases and significant at more than 80% confidence in the remaining four cases tested. In addition, the underwriting test indicated that this alternative was more accurate than the current method at 95% confidence in four of the five cases tested and at 90% confidence in the fifth.

Except for the significance of the Wilcoxon test, these results are mirrored in every state but Connecticut for small classes. There are also general improvements relative to the current methodology in most of the comparisons for medium and large classes, though some situations also exist where the current methodology may provide slightly closer estimates in those classes.

The consistency tests reflect similar indications. This should not be surprising since the use of more years of experience automatically adds to the number of years necessary to completely replace the data used in the methodology. In fact, in every comparison but two, the weighted average variance resulting from using five years of data was less than that under the current methodology.

In all cases the Wilcoxon Statistic indicated that using five years of experience resulted in smaller variances from class to class in the consistency test than the current method. In all states but Maine these differences were significant at the 90% confidence level.

2. Experience Period -- Fours Years of Data

The use of four years also seems to improve the mean square error of the forecast class relativities. The apparent improvement in accuracy over the current methodology does not appear to be as substantial as the gain from using five years of data.

The results of the consistency test were mixed in using four years of experience. In the two states tested the current method gave a lower average variance in one (Maine) and higher in the other (Florida). In both cases the Wilcoxon Statistic indicated that the alternative methodology produced lower variances but was significant only in Maine. The results for various sized classes generally follow the same pattern.

3. Loss Limitation -- One-Half Current Limit

The differences noted with the five credibility alternatives and three loss limitation alternatives are not as marked as those in using five years of data. Of the credibility and

CLASSIFICATION RATEMAKING

loss limitation alternatives, using losses limited at one-half the current limitation seems to provide the most significant improvement in indications of relative differences in costs among the classes.

The tests for this loss limitation alternative are not as unanimous as were the indications for the use of five years of data. In comparing the square difference index over time, this alternative seemed to produce a greater impact than all alternatives other than adding to the experience period and one of the credibility alternatives.

Five of the six states tested had lower mean square errors using half the current loss limitation compared to the current methodology with the corresponding Wilcoxon Statistic significant only in one. In four of those five states, however, the Wilcoxon Statistic indicated that the current method tended to provide closer estimates, with none of the results significant with 90% or more confidence.

The underwriting test indicates that this alternative provides more accurate estimates than the current method in five of the six states tested. In four of these the difference is significant at the 95% confidence level. The differences in the other two states are not statistically significant.

These results carry over to small classes. In fact, in every state tested, there is an improvement in the mean square error for small classes using this loss limitation as compared to the current method. On the other hand, the corresponding Wilcoxon Statistics gave conflicting indications with the current method indicated as more accurate in five states and the alternative in the other state. In only two of the cases are the differences significant at more than 90% confidence, one in favor of each method.

Differences for medium sized classes are similar. Again, using half the current loss limit produced lower mean square errors in four of the six cases with equally split indications from the Wilcoxon Statistic. In this case none of the Wilcoxon Statistics are significant at the 90% confidence level.

This alternative tended to reduce the variances in our consistency test for six of the seven states tested and was unchanged in the seventh. The resulting Wilcoxon Statistics also indicated that this alternative produced lower variances than the current methodology. In four of the seven states tested this difference was significant at the 90% confidence level.

CLASSIFICATION RATEMAKING

With only two exceptions, the use of half the current loss limit resulted in smaller average variances for all state and class sizes. Those exceptions were for large classes in Connecticut and Illinois. The Wilcoxon Statistics were positive in all cases and significant for small classes in Connecticut, Florida, Illinois, Maine and Nebraska. These statistics were significant for medium classes in Florida, Illinois, and Nebraska but were not significant for large classes where we used the normal approximation for the Wilcoxon Statistic.

4. Credibility Formula -- Double Current Full Credibility Standard

After the alternatives of using five years of data and of using half the current loss limitation, the next most noticeable difference from the current methodology appears to arise from doubling the full credibility standard. In all states tested, this alternative gave lower mean square errors than the current methodology. For all but two states the Wilcoxon Statistic indicated that the alternative using double the current full credibility standard gave more accurate indications of future relative loss costs than the current methodology. The differences were significant at greater than 90% confidence in four of those cases.

The underwriting test also indicated that using double the current full credibility standard produced more accurate indications of relative cost differences by class in all of the seven states analyzed. In four of these the difference was significant at 95% confidence while the differences in the remaining three states were not significant at this confidence level.

Using double the current full credibility standard also produced lower mean square errors for small and medium sized classes in six of the seven states reviewed. The Wilcoxon Statistics, however, indicate that the current method is more accurate in three of the states for small classes and in one state for medium classes. Two of the differences for small classes are significant at the 90% confidence level while for medium classes in five of the states the Wilcoxon Statistic is significant. In these latter four states, the statistic indicated that using double the current full credibility standard produced more accurate indications of relative cost differences among the classes.

In all seven states tested, doubling the current full credibility standard reduced the average variance in our consistency test. In every case the Wilcoxon Statistic lead to the same conclusion and was significant at greater than a 99% confidence level.

As with the use of five years of data, this result should not be surprising. Lessening the credibility given to an individual class increases that given to the current on-level pure premiums, thereby introducing added stability in the indications.

CLASSIFICATION RATEMAKING

There are some differences by class size. Using double the current full credibility standard produced smaller average variances for small classes in all seven states tested. In medium classes, the variance is smaller in all but one state. However, the average variance for large classes in Colorado, Connecticut and Florida, all large states, increased when double the current full credibility standard was used.

In none of the cases was the Wilcoxon Statistic negative, that is, in no case did that statistic indicate that the current method resulted in generally lower variances than using double the current full credibility standard. As with the overall indications, the differences were significant for small classes in all states but were not significant for medium sized classes in Colorado, Illinois and Nebraska. Significance of the differences for large classes were mixed.

5. Credibility Formula -- Payroll Based Credibility

Using payroll as a credibility base generally produces less change from the current methodology than the alternatives discussed to this point. In four of the seven states reviewed, this alternative produced a smaller mean square error than the current method. In four cases, however, the Wilcoxon Statistic indicated that the current method produced more accurate results, with the difference significant at the 90% confidence level in one state. In the remaining three states where the Wilcoxon Statistic indicated that using payroll based credibility gave more accurate results, the difference is significant at the 90% confidence level in two.

The underwriting test also gave quite mixed results. That test indicated that using payroll based credibility improved accuracy in five states, two significant at the 90% level. On the other hand it also indicated that the current method is more accurate in two states, both of which are significant at the 90% level.

In five of the seven states the mean square error for payroll based credibility projections in small classes is less than that of the current method. In two cases the Wilcoxon Statistic confirms this difference at the 90% confidence level. Only three of the Wilcoxon Statistics indicate the current method is more accurate and only one of the differences are significant at this level.

The current method seems to be more accurate at forecasting relative cost differences for medium sized classes. The mean square error is less for the current method than for payroll based credibility in four states, with the Wilcoxon Statistic in two of these states

CLASSIFICATION RATEMAKING

significant at the 90% confidence level. In only one state is using payroll based credibility significantly more accurate at this level using the Wilcoxon Statistic.

In two cases the use of payroll based credibility reduced the average variance in our consistency test. In every case the Wilcoxon Statistic was positive, indicating that this alternative reduced the variance of the various classes. In four of our test states, Colorado, Connecticut, Florida and Illinois, the statistic was significant at greater than the 99% confidence level. In the remaining three test states, Maine, Nebraska and Oregon, the difference is not significant.

Maine and Nebraska are the smallest of the states tested. It seems, then, that using payroll based credibility may improve consistency in larger states more than in the case of smaller states.

For smaller classes, the payroll based credibility reduced the average variance in all states and three of the states are significant at the 99% level, though the indication for Florida is significant at the 90% confidence level but not at the 95% level. For medium sized classes, however, Nebraska shows a smaller variance for the current method, though both variances are quite small. The Wilcoxon Statistics are all positive and are significant in Colorado, Florida, Illinois, and Oregon.

In the consistency test, the average variances for large classes are increased only in Connecticut relative to the current methodology. In Florida and Illinois, the difference was significant at more than a 98% confidence level.

6. Other Credibility Formulas -- 0.5 Power, 0.8 Lower, and Claim Count for Volume

The differences in forecast accuracy for the remaining three credibility alternatives did not appear to be as significant as those discussed to this point. In many cases the alternatives produced lower mean square errors than the current methodology. However, in only one case was the difference in the Wilcoxon Statistic significant. These cases were both for the alternative of using the square root, or .5 power, in place of the 2/3 power in the current credibility formula.

In Maine the Wilcoxon Statistic indicated that the alternative was more accurate than the current method at the 90% confidence level while the test for Nebraska indicated the reverse at the same confidence level. These same patterns held for small classes in both states.

CLASSIFICATION RATEMAKING

For this alternative the underwriting test provided conflicting results. That test indicated that the current method was more accurate in all three states tested with the difference significant at the 90% confidence level in Maine and Nebraska.

In only one other case, that of using 0.8 power in the current formula, was the difference indicated by the underwriting test significant. In that case, Florida, the alternative was indicated to produce more accurate results.

The use of the square root, or .5 power, in the credibility formula tended to increase the variance of the consistency test relative to the current method for all class sizes in one state. In the other two states, the results were mixed.

The Wilcoxon Statistic for the consistency test was positive in all cases, indicating that the .5 power in the credibility formula was more consistent at identifying relative loss cost differences than the current NCCI methodology. The differences were significant at more than the 99% confidence level in all cases. Similar results held for small classes in all states tested. For medium classes the significance of the differences were more than 98% and, where we used the normal approximation, greater than 95% for large classes.

The remaining alternative credibility formulas reviewed, the use of .8 power and the use of claim count based credibility, both resulted in lower average variances in the consistency test and in positive Wilcoxon Statistics that were significant at greater than the 99% confidence level.

Similar results generally held for small, medium and large classes. For medium classes, however, the results were not significant in Maine. For both Florida and Maine, the results for large classes were not significant.

7. Other Loss Limitations

The remaining alternative loss limitations did not appear to noticeably improve the accuracy of predicting relative loss cost differences among classes. In none of the cases were differences noted by the underwriting test significant at the 90% confidence level.

Generally, for Florida both the other loss limitation alternatives produced higher mean squared errors than using half the current limit or even the current methodology. In fact, the Wilcoxon Statistic indicates that the current methodology is more accurate than using

CLASSIFICATION RATEMAKING

unlimited losses at an 80% confidence level. Results for small and medium sized classes are similar but not as statistically significant.

In Maine the sliding scale alternative resulted in higher mean squared errors than using half the current loss limitation. In both cases, however, the Wilcoxon Statistic indicates that both are significantly more accurate than the current methodology. The corresponding results for small classes are the same while for medium classes the Wilcoxon Statistics seem to indicate that the current method provides more accurate results and, in one case, significantly so.

The use of unlimited losses and of the sliding scale loss limitation in classification ratemaking produced a higher average variance in Florida and a lower variance in Maine in our consistency tests. In all cases the Wilcoxon Statistic were positive, indicating that the alternative methodology was more consistent than the current NCCI methodology. In the case of unlimited losses, the differences were not significant for either state while for the sliding scale limitation, the differences were significant at greater than a 99% confidence limit.

All sized classes in Florida experienced higher average variances under both of these alternative loss limitations than under the current methodology. In Maine, small and large sized classes had lower average variances under both alternatives and medium classes had a lower average variance.

In all cases the Wilcoxon Statistics are positive and are significant at above the 95% confidence level in Florida for small, medium and large sized classes for both alternatives except for small classes under the sliding scale alternative. It is also significant for small classes in Maine under the sliding scale loss limitation.

We again remind readers that the accuracy tests for the various loss limitations were conducted using losses at those limits. These conclusions thus refer to the relative accuracy and consistency of the current methodology in projecting losses at those limits. In the end, though some expected improved relative accuracy and consistency using a sliding scale loss limitation, this expectation was not borne out by our test. This could possibly be due to the choice of scaling, the limitations used here, or the states used for the tests. As in other areas, we believe that the methods developed in this examination can be used by NCCI to test other alternatives.

CLASSIFICATION RATEMAKING

CLASSIFICATION RATEMAKING

V. EVALUATION OF INDUSTRY GROUP DIFFERENTIAL PROCEDURES (Objective 4b)

A. Data Sources

This portion of our analysis was based on data in the format of Appendix A-VII from NCCI filings. These data were prepared in conjunction with our request for alternative rate calculations using four or five years of data and reflect that added experience. We also received similar exhibits based on the current NCCI three-year methodology.

We were able to compare actual policy year 1987 losses at first report with the expected losses based on three and five years of data for Colorado, Connecticut, Illinois, Maine, and Nebraska, actual policy year 1988 losses for Utah with expected losses based on three and five years of data and actual policy year 1987 losses with expected losses based on three and four years of data for Florida and Maine.

B. Methodology

NCCI assumes that three years of experience for the individual industry groups is fully credible. The request for proposals asked us to address the question as to whether use of more years in calculating industry group differentials would improve the methodology.

It is not unusual in property and casualty ratemaking to use progressively more years of experience as the level of detail required increases. This is one characteristic of the current NCCI methodology in that the overall indication for a state is based on one policy year and one accident year of data but classification rates explicitly make use of three years of experience. Therefore, the use of five or more years of classification experience does not preclude the use of three years of industry group experience.

The tests applied here differ from those for the alternatives mentioned so far. Rather than testing the impact of an alternative on the rates of individual classes, we considered the impact of changing the number of years on the industry group differentials.

CLASSIFICATION RATEMAKING

In this case, the expected losses E_{ij}^k for industry group i , state j and alternative k equals the premium P_{ij}^k times the loss ratio for all industry groups combined for state j . This assumes that all of the industry groups will achieve the same loss ratio. The variations from this assumption measure the error from the objective of the industry group ratemaking process. We tested alternatives to measure whether they reduce the error.

The tests of the alternatives included (1) an accuracy test using (a) the Wilcoxon Statistic and (b) the mean square error and (2) consistency test similar to the one used for analyzing classification ratemaking alternatives.

The underwriting test was not used because there are only three industry groups, not the hundreds of classifications to which the test was applied in the previous sections of this report. The impact statistic is also not specifically calculated because with only three groups, the difference in indicated industry group relativity gives an immediate measure of the impact of the change.

We tested the significance of tests using the Wilcoxon Statistic:

$$W_j^* = \sum_{i=1}^3 D_{ij}$$

where D_{ij} is defined as:

$$D_{ij} = \text{Rank}(|SE_{ij}^1 - SE_{ij}^2|) \times \text{Sign}(SE_{ij}^1 - SE_{ij}^2)$$

The statistic W_j^* can only take on the values -6, -4, -2, 0, 2, 4, and 6. Under the null hypothesis that the corresponding square errors are not different, the probability that this

CLASSIFICATION RATEMAKING

statistic is equal to 0 is 0.25 while the probability it takes on any of the other six possible values is 0.125.

In addition to calculating the Wilcoxon Statistic for these years and states we also calculated the mean square error, defined as:

$$MSE_j^k = \frac{\sum_{i=1}^3 P_{ij}^k SE_{ij}^k}{\sum_{i=1}^3 P_{ij}^k}$$

This is the weighted average of the corresponding square errors using the adjusted manual premiums from the particular alternative as weights.

We were thus able to make these comparisons of 1987 losses with the expected losses given three and five years of data for Colorado, Connecticut, Illinois, Maine, and Nebraska and with 1988 losses for Utah. We also compared the expected losses with the 1987 losses in the 1990 revision given three and four years of data for Florida and Maine.

The consistency test is similar to that used for classifications. The overall average differential was calculated by combining premiums and losses for all available states. This information was based on the expected and adjusted losses from the second pages of NCCI Exhibits A-VII corresponding to the various states, years and alternatives.

As with the analysis discussed in section IV above, we then compared the industry group differentials for a given state with the combined differential for the same year. If there were little difference in the relationship from one year to the next, we concluded that the corresponding method was relatively stable. On the other hand, if there were wide differences from year to year, we concluded that the corresponding method is unstable.

To test this, we calculated the ratios of the industry group differential in a state and a year with that of the combined experience for the same industry group and year. We then calculated the variance of the resulting ratios over time for the same state. As with the comparison of actual with expected losses, we used the Wilcoxon Statistic to test the

CLASSIFICATION RATEMAKING

significance of differences indicated. In this case, rather than comparing the square errors of the alternative approaches, we compared the corresponding variances.

Appendix C to this section contains examples of these calculations.

C. Conclusions

The accuracy tests give a mixed result. In five of the eight cases tested, the current method gave a lower mean squared error than the alternative with more years of experience. The Wilcoxon statistic, which we used to test the significance of the differences, also provided mixed results.

The following table summarizes the resulting mean square errors (MSE) and Wilcoxon Statistics, where comparisons were available. Note that for all states but Utah, the comparison was based on 1987 data while 1988 was used for Utah.

Comparison of Mean Square Errors for Industry Group Differentials

<u>State</u>	<u>Alternative</u>	<u>3 Year MSE</u>	<u>Alternate MSE</u>	<u>Wilcoxon Statistic</u>
Colorado	5 Years	21,882	297,140	-4
Connecticut	5 Years	1,788,346	2,009,125	-2
Florida	4 Years	1,968,718	2,274,558	-2
Illinois	5 Years	438,892	240,558	6
Maine	4 Years	467,866	586,205	0
Maine	5 Years	467,866	341,499	2
Nebraska	5 Years	63,674	53,470	2
Utah	5 Years	26,001	41,108	-4

Recalling that the maximum value that the Wilcoxon Statistic can take is 6 in this case, a result of 6 would lead to the rejection, with the most confidence possible with this test, of the null hypothesis that the square errors of the corresponding alternatives are equal.

The negative values for Colorado, Connecticut, Florida (4 years), and Utah indicate that, based on the Wilcoxon Statistic, the three year approach gives a better approximation than

CLASSIFICATION RATEMAKING

the alternatives. If the null hypothesis is true there is a 12.5% chance of obtaining a value of -6 and a 25% chance of obtaining values of -4 or -6.

The following table, similar to the one above, summarizes the results of the comparison of the consistency of the two alternatives:

Comparison of Average Variances for Industry Group Differentials

<u>State</u>	<u>Alternate</u>	<u>Average Variance for 3 Year</u>	<u>Average Variance for Alternate</u>	<u>Wilcoxon Statistic</u>
Colorado	5 Years	0.00027	0.00017	4
Connecticut	5 Years	0.00172	0.00203	-4
Florida	4 Years	0.00154	0.00222	-6
Florida	5 Years	0.00045	0.00026	6
Illinois	5 Years	0.00021	0.00047	-2
Louisiana	5 Years	0.00099	0.00011	6
Maine	4 Years	0.00319	0.00210	6
Maine	5 Years	0.00119	0.00142	0
Michigan	5 Years	0.00042	0.00033	2
Nebraska	5 Years	0.00088	0.00055	6
North Carolina	5 Years	0.00095	0.00005	6
Oregon	5 Years	0.00065	0.00035	4
Utah	5 Years	0.00246	0.00070	6
Wisconsin	5 Years	0.00021	0.00025	-4

Here the comparisons with 5 years of data were made using all the listed states as a benchmark. For comparisons with 4 years of data, only Florida and Maine, which were the only states for which 4 years were run, were used.

Except for Wisconsin, for which only two rate revisions were available, and Illinois, using five years of data results in a lower variance in the relativities. Many of the comparisons resulted in Wilcoxon Statistics of 6, the highest possible, leading to the rejection of the null hypothesis with the most confidence possible. However, there are cases where the difference in variances is not as significant.

CLASSIFICATION RATEMAKING

The stability apparently gained by using five years of data should not be surprising. Results from one year to the next should be expected to be correlated, since, in the case of five years of data, each successive revision uses four years of policy year experience that were used in the previous revision.

As we mentioned above, we believe that at least as many years should be used in calculating classification relativities as are used in estimating industry group differentials. We have seen, at least from these indications, that using five years of data appears to provide more consistent and closer estimates than the current three years.

CLASSIFICATION RATEMAKING

VI. EVALUATION OF ALTERNATE TREND APPLICATION (Objective 4c)

A. Data Sources

As with the analysis for Objective 4a above, this portion of our analysis was based on rate revisions for a single policy year in several states. The underlying rate revisions were provided by the NCCI.

B. Methodology

The current NCCI methodology adjusts the indicated pure premiums to reflect the trend in loss costs per unit of exposure between the experience period used in the ratemaking methodology and the time for which the rates are applicable. In the current classification ratemaking methodology a single factor is used to adjust all indemnity losses, independent of the policy year. A separate factor is used to adjust medical losses.

In order to test the impact of possible bias introduced by this procedure, we asked the NCCI to calculate 1990 rates in Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon using a separate trend factor for each policy year of data.

C. Conclusions

We would expect bias in the current methodology if a particular class shows marked increase or decrease in volume over the experience period. A comparison of the square difference index that we developed shows that calculating separate trend factors by policy year makes the least difference of all tested alternatives in all but one state. In that single exception, the alternative trend method gave the second lowest square difference index of the forty-two tested alternatives.

On the other hand, the change is relatively easy to make, it is theoretically more correct, some classes may have significant changes in rates, and the change will be more significant if five or more years of data are used. Therefore, we recommend that NCCI apply trend on a year by year basis.

CLASSIFICATION RATEMAKING

CLASSIFICATION RATEMAKING

VII. EVALUATION OF "ALL OTHER" INDUSTRY GROUP COMPOSITION

During the course of this examination, the Examination Oversight Committee expressed some concerns regarding the content of the "All Other" industry group. The discussion in this section presents our analysis of that industry group and the conclusions that we reached.

A. Data Sources

We reviewed data from two states, Michigan and Pennsylvania, which have undergone changes in their heavy industrial economies. We also included Maine since the make-up of the "All Other" category is currently a significant issue in that state.

We analyzed payroll and present on rate level pure premiums for these three states using information from 1991 rate filings. The Maine data was taken from Appendix B-II (pgs. 75 through 110) of the NCCI filing. The Michigan data source was Appendix B-II (pgs. 56 through 90) of the Compensation Advisory Organization of Michigan filing. The Pennsylvania data was from the Pennsylvania Compensation Rating Bureau filing classbook (including large risks), pages 191 to 346.

B. Methodology

Our review was undertaken with three guiding principles:

1. Each new industry group should be statistically reliable. In this respect, expected losses and payroll can be compared to the smallest existing industry group (i.e., "Contracting").
2. Each new industry group should have less dispersion of class pure premiums about the new group average pure premium than the original group.
3. The occupational classes within the new industry groups should be more homogeneous. That is, the occupations within each group should have some sort of common characteristics.

CLASSIFICATION RATEMAKING

Principle 1 is intended to assure that the credibility of the industry groupings within a state will not be diminished significantly as a result of modification. In the case of office employees, the following table compares the contracting classes, the office employee class and the all other class excluding office employees.

<u>State</u>	<u>Industry Group</u>	<u>Payroll (Millions)</u>	<u>Ratio to "Contracting"</u>	<u>Expected Losses (Millions)</u>	<u>Ratio to "Contracting"</u>
ME	ALL OTHER (excluding office)	\$ 7,769	5.26	\$306	1.48
	OFFICE EMPLOYEES (8810)	3,682	2.49	15	0.07
	CONTRACTING	1,478	1.00	207	1.00
MI	ALL OTHER (excluding office)	\$ 45,906	6.81	\$1,047	1.98
	OFFICE EMPLOYEES (8810)	32,056	4.75	93	0.18
	CONTRACTING	6,743	1.00	530	1.00
PA	ALL OTHER (excluding office)	\$146,271	7.78	\$2,440	2.34
	OFFICE EMPLOYEES (953)	81,801	4.35	186	0.18
	CONTRACTING	18,798	1.00	1,043	1.00

It is seen that the office employees class has significantly higher payrolls than the entire contracting industry group. While the losses are significantly less, substantial credibility will still exist with expected loss volumes of \$15 million, \$93 million and \$186 million.

Principle 2 is intended to assure that equity value is gained from any change; i.e. that there is statistical evidence that greater homogeneity of risks within the new ratemaking categories is achieved. For this analysis, we have used the dispersion of class pure premiums about the corresponding industry group pure premium as a medium for evaluating relative homogeneity of each group.

CLASSIFICATION RATEMAKING

A commonly used measure of relative variation within different populations is the coefficient of variation (c.v.). The c.v. in this example is the standard deviation of the class pure premiums divided by the industry group pure premium. Ideally, the c.v. should be reduced by any modifications in industry groups that are intended to increase homogeneity.

From a purely statistical standpoint, the c.v. could be reduced to zero by simply creating a separate industry group for each class. However, by stratifying the ratemaking data, Principle 1 would soon be violated.

The table below presents the c.v.'s inherent in the current "All Other" group and a hypothetical "All Other - Excluding Office Employees" group. Significantly, the c.v. of the new miscellaneous category is reduced.

<u>Payroll State</u>	<u>Industry Group</u>	<u>(Millions)</u>	<u>c.v.</u>
Maine	ALL OTHER	\$ 11,451	1.60
	ALL OTHER - EXCLUDING OFFICE EMPLOYEES	7,769	1.23
Michigan	ALL OTHER	\$ 77,962	1.50
	ALL OTHER - EXCLUDING OFFICE EMPLOYEES	45,906	1.12
Pennsylvania	ALL OTHER	\$228,072	1.46
	ALL OTHER - EXCLUDING OFFICE EMPLOYEES	145,271	1.16

Principle 3 is intended to assure that any new industry group is created under the same premise as the existing industry groups. As we are discussing only the office employees occupational class, this principle is obviously not violated.

C. Conclusions

We recommend that NCCI pursue the feasibility of creating new, more homogeneous industry groups from the existing "All Other" group. These groups should be created without violating any of the three principles described above.

CLASSIFICATION RATEMAKING

As shown with the preceding example, it is feasible and desirable to segregate the "Office Employees" class as an industry group separate from "All Other." The class is large and different enough to warrant such a modification. Also, as shown in Appendix E to this section of the examination report, many of the classes that would remain in the "All Other" group suggest work activity that may be similar to office employment (e.g. attorneys, physicians including clerical and accounting). We expect that the c.v. of the new miscellaneous category would be further reduced by transferring some additional classes to the "Office Employees" industry group. However, the "All Other" group should not be diminished to the extent that Principle 1 is violated.

We stress that other sub-groups are possible and could vary by state.

CLASSIFICATION RATEMAKING

VIII. EVALUATION OF AN ALTERNATE TO NATIONAL RELATIVITY

A. Data Sources

As with the analysis in sections IV and VI, we based our analysis on a comparison of rates calculated under the current methodology and a single alternative.

B. Methodology

The pure premium indicated by national relativity is the third component of the pure premium derived by formula. We recognize that there has been a recent change in the calculation of these pure premiums. The original method was discovered to cause the pure premium indicated by national relativity to be overstated in the case that a state had a class or classes not present in one or more other states.

We understand that the current NCCI methodology corrects for this by calculating the adjustment factor applied to losses in other states using only classes existing both in the state under consideration and in the other state. In addition, we understand that the revised NCCI method now balances pure premiums indicated by national relativities by industry group within a state.

Some discussions regarding the current classification ratemaking methodology raise concerns with the applicability of pure premiums indicated by national relativity to class pure premiums for a particular state. We recognized these concerns and developed an alternative that keeps the current methodology but introduces a regional component to the pure premiums determined by national relativities.

This alternative calculates two separate sets of partial pure premiums and combines the two to replace the current pure premiums indicated by national relativity. The first set is simply the current pure premiums indicated by national relativity in the current ratemaking methodology.

The second set is calculated in a similar manner but includes only the states in the same NCCI region as the target state. The pure premiums indicated by national relativity are then replaced by the credibility-weighted average of these two indications. The weight

CLASSIFICATION RATEMAKING

given to the regional partial pure premium is calculated using the same formula as used for pure premiums indicated by national relativity. We asked the NCCI to calculate 1990 rates in Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon using this alternative.

C. Conclusions

This regional pure premium application generally showed small differences with the current methodology in most situations. In fact, in most states, the square difference index for this alternative was second smallest only to that for the alternative trend application. There appears to be little evidence to support making any change in this direction at this time.

CLASSIFICATION RATEMAKING

IX. EXCESS LOSS ANALYSIS

During the course of our analysis a question arose regarding the treatment of losses in excess of the loss limitation in the NCCI classification ratemaking procedure. Currently, such losses are implicitly included in the off-balance correction factor which, except for swing limitations, is uniform for all classes in an industry group. We analyzed whether, given available data, there are significant differences in excess experience among classes in the various industry groups.

A. Data

We compared unlimited losses with those limited to the current NCCI loss limits for three policy years of data. We used Schedule Z data tabulations from the NCCI as the source of the unlimited losses and the corresponding NC235 data tabulations as the source of limited losses. These tabulations contained data for policy years 1985 at third report, 1986 at second report and 1987 at first report and were available for Connecticut, Florida, Illinois, Maine, Michigan, Nebraska, North Carolina, Oregon, Utah and Wisconsin.

B. Methodology

The goal of this section's test is to determine if a class or classes have significantly different expected losses above the loss limitation than the remaining classes. If this is a case, the current NCCI methodology may introduce subsidies in the classification rates.

To this end, we calculated the following two statistics for each class i and policy year j :

$$GILF_{ij} = \frac{\sum_{k \neq i} UL_{kj}}{\sum_{k \neq i} LL_{kj}}$$

CLASSIFICATION RATEMAKING

$$ILF_{ij} = \frac{UL_{ij}}{LL_{ij}}$$

Here UL_{ij} denotes the unlimited losses for class i in policy year j and LL_{ij} denotes the corresponding limited losses. In addition, ILF_{ij} is the excess loss factor implied by the data for class i in year j and $GILF_{ij}$ denotes the industry group excess loss factor. The summation is taken over all other classes in the industry group containing class i . This latter restriction reflects the current NCCI procedure of balancing rate level indications by industry group in determining the off-balance factors.

We will conclude that one class is expected to experience excess losses that are significantly different from the others in the industry group if the above factors are significantly different. We would expect the excess loss factors to be greater than 1.00 and, at least theoretically, unlimited.

We thus assumed for each class i that $GILF_{ij}-1$ and $ILF_{ij}-1$ are both independent random samples of size 3 from independent lognormal distributions. These assumptions result in statistics that have the properties identified at the end of the previous paragraph.

The natural logarithm of a lognormal variable is normal, and we can test the significance of the difference between the corresponding factors by testing the significance of the difference between the sample means:

$$GM_i = 1/3 \sum_{j=1}^3 \ln(GILF_{ij}-1)$$

$$M_i = 1/3 \sum_{j=1}^3 \ln(ILF_{ij}-1)$$

CLASSIFICATION RATEMAKING

The above assumptions lead to the conclusion that $\ln(GILF_{ij}-1)$ and $\ln(ILF_{ij}-1)$ form independent random samples from normal distributions with possibly different variances. Under the null hypothesis that the two underlying means are equal:

$$H_0: E[GM_i] = E[M_i]$$

The difference between class excess losses and industry excess can be tested by the following statistic which has a t distribution with 2 degrees of freedom:

$$T_i = \frac{GM_i - M_i}{S_{z_i} / \sqrt{3}}$$

where

$$Z_{ij} = \ln(GILF_{ij}-1) - \ln(ILF_{ij}-1),$$

$$\bar{Z}_i = 1/3 \sum_{j=1}^3 Z_{ij}, \text{ and}$$

$$S_{z_i}^2 = 1/2 \sum_{j=1}^3 (Z_{ij} - \bar{Z}_i)^2$$

We can conclude that class excess losses are significantly different from the industry group excess losses with confidence p if $|T_i|$ exceeds the values shown in the table below:

CLASSIFICATION RATEMAKING

Critical Values

p	<u>T_i greater than</u>
90%	2.920
95%	4.303
99%	9.925

Source: Standard Table for t Statistics

With only three policy years available, we recognize the possibility that a class will experience no losses in excess of the limit. In such cases we calculated UL_{ij} as $LL_{ij}+1$. We also excluded all classes with no losses experienced in any policy year.

C. Conclusions

As shown in Exhibit B-4, a substantial proportion of classes in nearly every state and industry group combination differ significantly from the average for the remainder of the industry group. The reader should exercise caution in interpreting the results shown in Exhibit B-4 for several reasons. First, these indications are based on three years of experience; one at first report, one at second and one at third. It is likely that this may not be sufficient for large losses to emerge for smaller classes or in smaller states and such losses if they do emerge may have an undue influence on the results. This may explain the results shown for Nebraska and Utah for some industry groups.

Second, the differences shown are between a class and the rest of the classes in the particular industry group. If only few classes in an industry group experience excess losses then the many "clean" classes could have test statistics indicating significant difference from the remainder of the group. Again, the lack of experience available limits the conclusions we can draw from these results. We have, however, developed a method that NCCI can use to further test the extent of difference that may exist.

CLASSIFICATION RATEMAKING

X. ADDITIONAL INFORMATION PREPARED BY NCCI

A. Introduction

In the later stages of this examination, NCCI used the methodology described in pages 34 through 36 to perform additional tests of the relative accuracy of the use of five years of data as compared with the current three years.

We have not been able to perform a detailed review of all the calculations NCCI used for this additional information. We have, however, been able to duplicate their results in a few test cases, including the use of first report for Colorado, Connecticut, Illinois, Maine, and Nebraska, and both the use of manual premiums and the use of development from first report for Illinois. Due to time constraints, we have not verified the remaining calculations.

B. Description of Tests

We understand that NCCI followed the methodology described in this examination report to obtain mean square error and Wilcoxon statistics comparing relative accuracy at first report for six additional states; Florida, Louisiana, Michigan, North Carolina, Oregon and Utah. We also understand that they extended this test to using second report data in the five states we tested using first report data; Colorado, Connecticut, Illinois, Maine and Nebraska.

In addition to extending the number of states and maturity of loss data, NCCI also made two modifications to our tests. The first modification removed our adjustment for the difference between manual and standard earned premiums.

The second modification replaced actual losses by developed losses. We understand that NCCI applied age to ultimate development factors to adjust actual losses to their expected ultimate level. Separate development was applied for serious indemnity, non-serious indemnity, serious medical and non-serious medical losses, using uniform development factors among the classes for each type of loss. For example, the same development factor was used for all classes to develop serious indemnity losses while a different factor was used to develop non-serious indemnity losses, and so forth.

CLASSIFICATION RATEMAKING

The development factors used were those that were used in the rate filing where those losses were at first report. For example, 1987 losses at first report were used in the calculation of 1990 rates. The 1987 losses were then developed to their estimated ultimate level using the first report to ultimate factors from the corresponding 1990 filing.

C. Discussion of Results

Appendix G to this section of the examination report presents the calculations supplied by NCCI. Though the mean square errors and Wilcoxon statistics are not unanimous as in our original tests, the general indications of our initial tests still appear to be supported by these additional calculations. In most cases, the mean square errors for the five year alternative are less than those for the corresponding tests using three years of data. In most cases the Wilcoxon statistics are positive and are significant in many, while negative values are only significant in one state.

For example, in the eleven states using first report data developed to ultimate, two of the Wilcoxon statistics were negative and nine were positive. Only one of the negative statistics was significant at the 80% level while six of the positive ones were significant at that same level.

For the most part, the additional NCCI tests performed using data for the five original states; Colorado, Connecticut, Illinois, Maine, and Nebraska, yielded results parallel to our original tests, though the Wilcoxon statistics are not quite as significantly positive. Thus, the adjustments made by NCCI do not appear to substantially affect the general indications derived from our tests.

We also note that we did not rely solely on the mean squared errors and Wilcoxon statistics in forming our conclusions. Probably the stronger indications arose from the application of the underwriting tests. In this case, the use of five years was significantly more accurate in identifying relative loss cost differences at the 90% confidence level for all states we tested.

Due to time constraints, NCCI has not been able to run similar tests for all the comparisons they provided. However, they did run these additional tests for the additional six states using first report, undeveloped losses. In these cases, the use of five years was significantly more accurate at the 80% confidence level in all states but Utah and Florida.

CLASSIFICATION RATEMAKING

Again, these results seem generally to follow the indications of our original tests.

(As part of an NAIC examination of NCCI, Milliman & Robertson, Inc. has completed a study of the classification ratemaking of the NCCI. The purpose of this appendix is to provide supporting data and calculations underlying the study).

RE: DATABASE AND DATA REQUEST - SECTION IIB4 CLASSIFICATION
RATEMAKING

Dear Mr. Yenke:

We are at the stage of our project where a database will be needed to test various assumptions and alternatives to the classification ratemaking system used by NCCI. We would like a database comprised of the attached list of states and national pure premiums to be compiled for test purposes. We believe supporting data for the last five rate filings (seven if possible) will be needed to provide a sufficient base to test alternatives. Data should be in adequate detail to provide testing of the following types of alternatives:

1. Varying the number of years up to five used in each class,
2. Different credibility formula,
3. Different credibility base,
4. Different adjustment factors,
5. Different loss limitations.

We realize retaining individual claimant detail at all report levels for the seven plus policy years involved is not feasible. We believe item 5 can only be tested using individual detail. Thus we may only be able to use the most recent filing to quantify the impact of change for that item. For the other items we could test the impact of the proposal changes using actual experience.

In addition to the availability of this data base we would like a list of critical values for the serious/non-serious split by state along with a procedural definition to calculate those values for each of the past seven years. It would be helpful if we could obtain this information within the next week.

In his letter to Mr. Berquist, Mr. Hager mentioned several enhancements to ratemaking methodologies. Two of these in particular appeared to deal with classification ratemaking, namely "Industry Group Differentials - improved method approved by Actuarial Committee (2Q, '90)" and "Investigation of Credibility Standards for National and State Pure Premiums used in Class Ratemaking (3Q, '90)."

Please include available written description and supporting discussion for these enhancements. As with the definitions of serious and non-serious, we would appreciate this information within the next week.

We will be talking to you at greater length in the next week to ten days to further clarify database requirements. In the meantime if you have any questions do not hesitate to call.

Best regards,

Roger M. Hayne

RE: CLASSIFICATION RATEMAKING INFORMATION, NAIC PROJECT,
SECTION IIB4

Dear Bob:

This letter is to request additional information regarding the classification ratemaking procedures employed by the NCCI and to present a more complete description of some of the analyses we will be requesting to be run. The first part of this letter addresses the request for additional information, and the second portion addresses the requested analyses.

Information Request

As you indicated, the Michigan filing seemed to present a fairly complete description of the classification ratemaking methodology. We believe we understand most of the procedures described, however we do, have a few detailed questions that we could not find answered in that filing.

1. In Section F of Appendix B-I-A we see how the losses for industry groups are adjusted for development, law changes, assessment changes and wage trend differentials. It is not clear from this section, however, where these loss totals come from. In fact, the total losses from Section F of Appendix B-I-A are close to but slightly less (within less than 1%) than the corresponding totals by policy year from the accompanying report titled "Undeveloped Losses and Cases by Type of Injury". That report appears to summarize the loss data that is used for the "A-Sheet" calculations. How do the losses in Section F of Appendix B-I-A relate to the data used for individual class ratemaking for individual classes included in the "Undeveloped Losses and Cases by Injury Type" report?
2. Also in Section F of Appendix B-I-A, it is not immediately clear how the pure premiums in column (1) of Part 1 are calculated. Are they the product of the "Underlying

Present Pure Premium" (for example, column (7) from Appendix B-I-B) and the payroll column (10) from that same appendix)? If not, how are these values calculated?

3. In our telephone conversation, you indicated that the national pure premiums were calculated using the NCCI's overall data base. Harwayne, in his 1977 paper in the Proceedings of the Casualty Actuarial Society, described the process used to adjust the countrywide experience. Specifically, that approach uses losses and payroll from the individual states to derive a single adjusted nationwide class pure premium for the state under review. In particular, current rates or resulting underlying pure premiums are not used in that calculation. Does the NCCI currently calculate the national pure premiums in this manner? How are trend adjustments made, if any?
4. We recognize that, to some extent, each state is unique. We understand that there may be exceptions to the class ratemaking procedure. Are such exceptions made? If so, what state(s) are affected? Are there class(es) that have exceptions? If so, what class(es) and in what state(s)?
5. The Michigan filing gives a detailed description of the full credibility standard and how partial credibilities are assigned. What is not clear is the reason for that particular formula. Does some description for the derivation of that formula exist? If so, please forward a copy to us.
6. The filings appear reasonably clear as to what loss limitations are used in the data and how those limitations are calculated. What is not clear is the rationale behind the selected limitations. What are the actual (dollar amount) limitations used, both currently and over the past seven years, by state?
7. We have not yet received the three items of documentation we requested in the top two paragraphs, page 2, of our November 30, 1990 letter.

Requested Analysis -- Years of Experience

As we previously discussed, one of the goals of our analysis is to review the impact of varying the number of years of experience used in classification ratemaking. What follows is a broad outline of how we envision that analysis would be accomplished. Due to limitations in the data available, some approximations have been necessary.

Please review this outline carefully to be sure we have given you sufficient direction to appropriately accomplish the desired goal. We welcome any questions or suggestions that will allow us to accomplish our goal as efficiently as possible.

We recognize that your detailed, day-to-day experience with this portion of the ratemaking methodology gives you a unique insight into the interaction of the various portions and the detailed data necessary for those calculations.

Thus, we need to be aware of any ambiguities or omissions in this outline that may affect the analysis. Therefore, we would appreciate the benefit of any insights you may offer in this regard.

We understand that the NCCI has readily available data from five (5) rate filings for the states we specified in our previous letter. As will become clearer below, the presence of additional data will greatly improve the results we will be able to obtain.

We thus understand that these readily available data sets will have loss and exposure data for the most recent seven (7) policy years. The most recent policy year is at the first report, the next is at the second report and the remaining five policy years are at the third (or possibly later) report. The third report would be available from the most mature policy year in each of the five retained filings.

We will assume in the following outline that later reports (fourth or fifth) are not available in classification detail by injury type (death, PT, ...). If, however, those additional data are available, we will modify our approach accordingly.

For the sake of discussion, we will denote these policy years as 1982 through 1988 respectively. By 1988 we denote the most recent policy year whose experience is available (at first report). Similarly 1987 denotes the year that is at second report in the most current filing, and so forth.

Our goal will be to use policy years 1982 through 1987 to provide forecasts for 1988. We would then compare those forecasts with the actual 1988 policy year experience that has emerged as a test of relative accuracy of the approaches.

We understand that the limitations in the data allow us to only directly test the impact of using four (4) years of experience, since only policy years 1982 through 1985 would be available to make rates for the 1988 policy year. We request that the NCCI perform the corresponding classification rate estimates to provide the basis for these comparisons.

Additional experience data for policy years 1981 and prior, using the above naming conventions, would substantially increase the value of this analysis. For example, if 1981 were available we would have two comparisons of the impact of four years versus the current three; 1981 through 1984 to forecast 1987 and 1982 through 1985 to forecast 1988, as well as a test for five years versus the current 3.

We also propose additional tests. We would like to test the amount of fluctuation in rates from one year to the next using four or five years of data as compared with the current three years. For this we will use five (or four) years from 1982 (1983) through 1986 to estimate 1989 classification rates. Similarly, we would use 1983 (1984) through 1987 to estimate 1990 classification rates and 1984 (1985) through 1988 to estimate 1991 classification rates.

We would then compare the changes by class to those resulting from the current methodology. Here again we request that the NCCI calculate the classification rate indications for comparison with the current methodology.

Adjustment of Loss Experience

Given our understanding of available data, and current methodology, several steps are necessary to adjust losses to proper levels for class ratemaking. These adjustments include:

1. Adjustments for benefit changes,
2. Adjustments for changes in assessments (where appropriate),
3. Loss development,
4. Inclusion of loss adjustment expenses,
5. Trend, and
6. Adjustment to calendar-accident year indications.

1 & 2. Benefit and Assessment Changes. The combined available data should provide sufficient detail to adjust past policy year losses to the benefit and assessment levels appropriate in the various rate calculations, even if the individual policy years were not used in the particular filing. Thus, for example, using the naming conventions defined above, the 1982 policy year data could be adjusted to a 1988 level by using the changes as evaluated in the filings for 1987 and 1988 rates, since 1982 would last be used to estimate 1987 rates in the current methodology.

3. Loss Development. We would prefer to have development history and experience to five reports available for development. If such history is available, for the purpose of these tests, use the development from fifth report to ultimate from the current filing but modify the development for policy periods making use of data at fifth and fourth reports for the most mature policy years. For example, if we are using 1982 through 1986, we would use 1982 at fifth report, 1983 at fourth report, 1984 at third report, 1985 at second report and 1986 at first report and use fifth-to-ultimate, fourth-to-ultimate, etc. factors.

We recognize that fourth and fifth report experience may not be readily available. As an alternative to this preferred approach we would have the NCCI apply the third-to-ultimate development to third report data for the most mature three policy years (two if a four-year alternative is tested). We would maintain the current approach for development of years at first and second report.

4. Loss Adjustment Expenses. The current procedure of applying a single factor could be used to include loss

adjustment expenses.

5. Trend. For the purpose of this exercise we propose to use the current procedure of a single trend factor for all policy years. A different portion of our analysis would incorporate different trends for each policy year. In this case, however, the trend would be calculated adjusting the average experience date to the midpoint for the experience used.

6. Calendar-Accident Year Adjustment. We understand that this factor is used to adjust for differences between the calendar-accident year experience used in the overall rate level indications and the policy year unit statistical data used for classification ratemaking. If more than three years of experience is used for classification ratemaking, then a precise adaptation of the current methodology would calculate this factor for using more than three years of experience. We recognize that sufficient data to accomplish this may not be available. If that is the case we then would approximate this factor by using the same adjustment factor as used in the three-year analysis.

Adjustment of Current Pure Premiums

We recognize that several adjustments are made to the last-approved "A-Sheet" pure premiums calculated by formula to derive the "Present On Level Pure Premium" used in the classification ratemaking. We understand these adjustments include:

1. Composite factor from the last approved filing by industry group (manufacturing, contracting, and other),
2. Effect of law and assessment changes by loss type (serious, non-serious and medical),
3. Effect of some subsequent benefit changes by loss type,
4. Adjustment to exclude loss adjustment expenses, uniform for all industry groups and loss types,
5. Adjustment for the change in the ratio of manual to earned premiums between the current rates and the proposed rates, uniform for all industry groups and loss types,
6. Adjustment for differential in wage trend among industry groups, and
7. Adjustment for industry group experience.

1. Through 5. The first five (5) adjustments do not appear to depend on the number of years of experience used in the analysis. The last two items, however, do.

6. Wage Trend Differential. We understand that the current methodology takes this trend adjustment from the midpoint of the experience period. As with the trend question above, we defer consideration of different trends until we analyze the

affects of changes in trend methodology later. At this juncture, then, we would calculate a single factor for each industry group similar to the current approach, but incorporating the full extended experience period, four or five years.

7. Industry Group Experience. We note separate factors are used to adjust prior pure premiums to reflect industry group experience. This is accomplished by comparing adjusted losses by industry group to expected losses by industry group. We propose to calculate these factors using the current approach, but incorporating the most recent four (or five) policy years of experience.

The loss portion would be adjusted for development and changes in law level and assessments. As with the development section above, we would prefer to use fifth and fourth reports for the two most mature policy years if the data are readily available. As an approximation we would use third-to-ultimate factors for each of the most mature three policy years. The separate adjustment noted above for the wage trend differentials would be used in this portion of the analysis.

The expected loss portion would be calculated using exposure from each of the four (five) years. The final adjustment factors would be based on the combined four (five) years of experience.

National Pure Premiums

The specific approach to be used here will depend on the answer to question 3 in the first part of this letter. If losses are used, we would use four (five) years of nationwide class losses in the analysis. Conceptually, this is little different from the current approach, except that more years are being used.

Credibility

This phase of our analysis will not separately consider the form or the basis for credibility factors. We would thus use the current credibility formula, but based on four (five) years of combined experience. Other phases of our study will address the question of credibility.

Derivation of Manual Rates

We would then request that final manual rates be calculated using the current methodology. We propose maintaining the same limitation to change contained in the current procedure. We would need to know, however, the classes that are affected by that limitation in the current method as compared to each of the alternatives as well as the difference in indicated changes in class pure premiums.

Requested Output

For each alternative outlined above we will need a computer diskette (IBM-PC/AT Compatible) and hard copy back-up containing at least the following information for each class:

1. Class number,
2. Total Payroll, (most recent year),
3. Derived by Formula Pure Premium by Loss Type (serious, non-serious, and medical) -- Current Method,
4. Derived by Formula Pure Premium by Loss Type (serious, non-serious, and medical) -- Alternative Method,
5. Final Manual Rate -- Current Method,
6. Final Manual Rate -- Alternative Method, and
7. In the case of the test using the first four years of experience, 1982 through 1985 to estimate 1988 rates in the above notation, also include:
 - a. Actual unlimited policy year 1988 losses,
 - b. Actual limited policy year 1988 losses and
 - c. Actual policy year 1988 exposure.

In addition to the impact on class rates, we will explore the impact of varying the number of years on industry group differentials. Thus, for each alternative we also request summaries of resulting experience similar to those contained in Section F of Appendix B-I-A of the Council's most recent Michigan filing.

Requested Analysis -- Application of Trend

An additional phase of our study includes reviewing the affect of changing the application of trend adjustments. For the purpose of this phase, we will maintain the current three-year experience base and only vary the application of trend. Keeping with this spirit, and recognizing that the approach used to quantify trend is the subject for a separate portion of our overall study, we also request that the current methodology be used to quantify trend.

The difference will be the calculation of three separate adjustment factors, one for each policy year of data used in the analysis. We would make a similar adjustment in calculating the factors for wage trend differentials used in adjusting industry group experience.

In both cases, the three factors would represent the change from the midpoint of the respective policy years rather than from the midpoint of the entire experience period. These

separate factors would be used to adjust losses for both class and industry group experience.

We request the same output information as requested in the above section regarding the number of years of experience to be used.

Other Items

You may be aware that our classification ratemaking portion of the examination will also deal with alternative credibility approaches and different loss limitations in the data. To some extent the descriptions of those approaches will depend on answers to questions at the beginning of this letter.

Thank you for your time in this matter. Please contact us to clarify any questions you may have.

Best regards,

Roger M. Hayne

RE: PROCESSING REQUESTS - NAIC PROJECT, CLASSIFICATION
RATEMAKING (IIB-4a-c)

Dear Bob:

This letter follows our phone conversation on Monday, February 11, 1991 in which you requested that we consider reducing the level of "A-Sheet" processing requests, due to the volume of processing involved. After discussion with the project team, we have assembled the following revised listing of processing requests which reduces the initial request by more than one-half.

In order to keep this letter to a manageable size, we will briefly describe the various processing requests and then indicate the number of states and years for which we are requesting the analysis.

1. Use of five years of data for classification ratemaking. States: All initially requested; Years: 5.
2. Use of four years of data for classification ratemaking. States: FL, ME; Years: 5.
3. Application of trend to individual years rather than the current single factor. States: CO, CT, FL, IL, ME, NE, OR; Years: 1 (Only most recent filing).
4. Alternate credibility, square root using expected pure premium. States: FL, ME, NE; Years: 4.
5. Alternate credibility, square root using payroll. States: All initially requested; Years: 4.
6. Alternate credibility, .8 power using expected pure premium. States: FL, ME; Years: 4.

Indianapolis • Los Angeles • Milwaukee • Minneapolis • New York • Omaha • Philadelphia
Phoenix • Portland • St. Louis • San Diego • San Francisco • Seattle • Washington, D.C.

Internationally WOODROW MILLIMAN

U.S.A., U.K., Canada, Netherlands, Australia, West Indies, Spain, Belgium, Denmark, Ireland, Norway and Mexico

7. Alternate credibility, current formula but double full credibility standard. States: All initially requested; Years: 4.
8. Alternate credibility, square root using claim counts. States: FL, ME; Years: 4.
9. Alternate loss limit, unlimited. States: FL, ME; Years: 4.
10. Alternate loss limit, 2.5 times current. Omit.
11. Alternate loss limit, .5 times current. States: All initially requested; Years: 4.
12. Alternate loss limit, sliding scale. States: FL, ME; Years: 4.
13. Regional Pure Premiums. States: All initially requested; Years: 1 (only most recent filing).

Please do not hesitate to call if any of these summaries are unclear.

Best regards,

Roger M. Hayne

RE: ADDITIONAL PROCESSING REQUESTS - NAIC PROJECT, CLASSIFICATION
RATEMAKING (IIB-4a-c)

Dear Bob:

This letter follows our earlier discussions and is intended to provide you with additional details regarding calculations supporting our investigation of classification ratemaking in section IIB-4a-c of our proposal to the NAIC. The areas of additional calculation will treat the credibility formula used, how it is applied in classification ratemaking and the loss limitation used in the data.

Before we go into the details of these requests, we would like to clarify the following three items from our letter of December 19, 1990:

1. We provided details regarding the use of more than three years in classification ratemaking and requested certain output from that exercise. In reviewing our proposal, you may also notice that we will consider the effect of varying the number of years used in the industry group calculations. We assume that you will need to assemble the workpapers for the industry group relativities in that process. In addition to the output requested in our December 19, 1990 letter, we request that you also provide us with the background to the group relativities similar in detail to what is contained in Section F of Appendix B-I-A of the Michigan filing. We will use this to address item IIB4b in our proposal.
2. Included in our December 19, 1990 letter was a request to have the classification rates recalculated using a different trend procedure (see pages 7 and 8 of that letter). Our earlier discussions did not specifically mention this item. Therefore, we would like to verify that this item

Albany • Atlanta • Boston • Chicago • Cincinnati • Dallas • Denver • Hartford • Houston
Indianapolis • Los Angeles • Milwaukee • Minneapolis • New York • Omaha • Philadelphia
Phoenix • Portland • St. Louis • San Diego • San Francisco • Seattle • Washington, D.C.

Internationally WOODROW MILLIMAN

U.S.A., U.K., Canada, Netherlands, Australia, West Indies, Spain, Belgium, Denmark, Ireland, Norway and Mexico

did not get "lost in the shuffle" with the focus on the larger project discussed in that letter.

3. In response to our request in item 4 (page 2) you suggested a sample of states with exceptions to the classification ratemaking procedure. We agreed to a sampling in our phone conversation. I recall that you were preparing such a sample and were going to send it fairly soon. We have not yet received that sample. If you need further guidance from us regarding that sample, please let us know.

Requested Analyses - General Comments

For the analyses outlined below we request output as described in our December 19, 1990 letter for Colorado, Connecticut, Florida, Illinois, Maine, Nebraska and Oregon. Those calculations should use policy years 1982 through 1984 to estimate 1987 rates (using the naming convention in that letter) and policy years 1983 through 1985 to estimate 1988 rates. In these cases we request "actual" experience also be included with the output, also as described in our earlier letter. This will allow us two comparisons of projected losses to "actual" losses with which to test the various credibility formulae.

To review relative stability we also request calculations using policy years 1984 through 1986 and 1985 through 1987. You will note that we are using three years of data in this request. As we discussed, our approach will be to restrict actual tests to varying one parameter at a time. We assume, from discussions, that analyses for these latter two filings should require much less additional effort than the analyses for the first two sets of years. If it turns out that substantial extra effort would be involved, resulting in a significant delay in providing results, then we could continue the analysis without these latter two sets of data. We would prefer to have the additional experience, however, to quantify the effect of years "rolling off" of the experience base for classification ratemaking.

We recognize that you may have detailed claim data available only for the most recent filing. Thus, you may only be able to provide calculations for one filing in response to our request regarding alternative loss limitations.

Requested Analysis -- Credibility

Our initial review of available and practical formulae generally used for credibility resulted in two general families:

$$Z = E/(E+K), \text{ and}$$

$$Z = \min\{1, (E/K)^p\}$$

where the notation x^p indicates x raised to the power p . The current credibility used by the National Council for experience rating is of the first type, while that used for classification ratemaking is of the second type. After review and discussion,

we have concluded that, as a practical matter, there are classes with sufficient experience to be fully credible by themselves. Unfortunately, unmodified, the first family of credibility formulae will never give full credibility ($Z=1$). Therefore, our request will concentrate on alternative credibility formulae that fall in the second family.

We request these tests using the following alternative credibility formulae:

1. For class experience use $Z = (\text{Expected Pure Premium}/N)^{.5}$, where N is the current full credibility standard by state and by loss type (serious, nonserious and medical). This is the "square root" rule applied to the current credibility base of expected pure premium. Base credibility for nationwide pure premiums using the same 25 and 300 claim full credibility standard, as is currently used, except use the square root instead of the current $2/3$ power in that formula.
2. For class experience use $Z = (\text{Payroll}/N)^{.5}$. For serious losses N is calculated as 25 times the average statewide serious loss per dollar of statewide payroll. For non-serious and medical losses N is calculated as 300 times the average statewide non-serious (medical) loss per dollar of statewide payroll. This replaces expected losses by payroll in alternative 1 above but attempts to maintain the same "average" full credibility standard. Base credibility for nationwide pure premiums using the same 25 and 300 claim full credibility standard, as is currently used, except use the square root instead of the current $2/3$ power in that formula.
3. For class experience use $Z = (\text{Expected Pure Premium}/N)^{.8}$, where N is the current full credibility standard by state and by loss type (serious, nonserious and medical). This variant of alternative 1 gives less credibility to small classes than the current NCCI "2/3 power" formula. Base credibility for nationwide pure premiums using the same 25 and 300 claim full credibility standard, as is currently used, except use the 0.8 power instead of the current $2/3$ power in that formula.
4. For class experience use $Z = (\text{Expected Pure Premium}/N)^{(2/3)}$, where N is double the current full credibility standard by state and by loss type (serious, non-serious and medical). This tests the sensitivity of the process to an increase in the full credibility standard. Base credibility for nationwide pure premiums using 50 and 600 claims for the full credibility standard using the current $2/3$ power in that formula.
5. For class experience use $Z = (\text{Number of Claims}/N)^{.5}$, where N is 25 for serious claims and 300 for nonserious and medical claims. This corresponds to the current credibility formula used for national partial pure premiums except using the square root. Base credibility for nationwide pure premiums using the same 25 and 300 claim full credibility standard, as is currently used, except use the square root instead of the current $2/3$ power in that formula.

Requested Analysis -- Loss Limitation

Loss limitations can affect the classification ratemaking procedure. We recognize that detailed claim data required to modify the loss limitation may not be available but for the most current filing. Thus, we limit our request in this regard to only the years for which such are available.

We request that the following limitation be tested:

1. No limit. Here all losses, without limit, are included in the classification ratemaking calculations.
2. 2.5 times the current loss limitation. This corresponds to limiting losses to 50% of the self-rating point, as compared to the current 20%.
3. 0.5 times the current loss limitation or double the revised state experience rating loss limitation point whichever is more convenient for you.
4. A sliding scale calculated as:

$$\text{limitation} = (.5 \times \text{current}) / (1 - Z)$$

where "current" denotes the current loss limitation and Z denotes the smallest class partial pure premium credibility using the current credibility formula. In this case large and fully credible classes do not have any loss limitation since as Z approaches 1 the formula for loss limitation gets arbitrarily large. On the other hand, small classes will tend to have lower limitations, approaching one-half the current limitation as Z approaches 0.

Requested Analysis -- Regional Pure Premium

For this analysis we wish to test an alternative to the nationwide partial pure premiums. This alternative is intended to give recognition to the partial pure premium indications in surrounding states.

For this alternative we request that you first calculate regional partial pure premiums, R, using the same procedure used for national pure premiums, except limiting states used to states in the same region as the state under review. For simplicity at this stage, please use the National Council's regions; North, South, and West.

We then request that you replace the national partial pure premium used in the "A Sheet" calculations by

$$Z \times R + (1 - Z) \times N, \text{ where}$$

$$Z = (\text{Claim Counts} / 25 \text{ or } 300)^{(2/3)}, \text{ and}$$

$$N = \text{Current Nationwide Partial Pure Premium}$$

January 25, 1991

Here, as in assigning credibility to nationwide pure premiums, the full credibility standard is 25 claims for serious and 300 for non-serious and medical. In this case, however, the number of claims is based on the number of claims in the region.

Bob, we hope that the above provides you with sufficient detail to complete the processing requests for this section of our analysis. Please call at your convenience to discuss any questions you may have regarding this or any other request.

Best regards,

Roger M. Hayne

APPENDIX B

CLASSIFICATION RATEMAKING

Appendix B

Summary of Accuracy, Consistency, and Impact Tests

This appendix contains exhibits that present detailed summaries of the results of various tests performed in comparing NCCI methodology with the various specific alternatives considered in this examination.

Exhibit B-1 presents a summary of the square difference indices for each of the alternatives tested. The definition of this statistic can be found on page 43 of this examination report. It is intended to measure the difference between the current NCCI methodology and the specific alternative. It does not provide any indication as to which is more accurate or more consistent.

In addition to showing the square difference indices, Exhibit B-1 also shows all of the alternative classification procedures considered in this portion of this examination. The states and years used for each alternative will be represented by a non-blank cell on that exhibit.

We selected the states to incorporate in the tests of various alternatives with an eye toward the volume of processing our requests would require. Our initial requests were for five consecutive rate filings for each of the twelve states using four and five years of data. In addition, we requested the remaining alternatives to be calculated for four consecutive rate filings for seven of the twelve target states.

After discussions with NCCI, given the volume for work this initial request required, we reduced the scope of our original request. The goal of this reduction was to decrease the overall work load while analyzing as wide a range of alternatives as possible.

Since actual loss data is only available for 1987 at first report, 1986 at second report and 1985 at third report, we were only able to apply our accuracy tests for alternatives having calculations for 1987. Thus, for example, we were only able to use Colorado, Connecticut, Illinois, Maine and Nebraska for the accuracy test in using five years of data even though this alternative was calculated for at least two years in all twelve of our sample states.

Similarly, the availability of data affected the consistency tests that we could perform. In the alternative with five years of data, we have three different sets of tests. The first represents those states for which alternative calculations were available for all four years,

CLASSIFICATION RATEMAKING

1987 through 1990, the second is for those having alternatives for 1988 through 1990 and the third for all twelve states. The remaining alternatives generally had data available for the same years for all states tested so that we only included one set of consistency tests. The results of all of these tests are shown in Exhibits B-2 through B-4.

Exhibit B-2 presents a summary of the results of the various comparisons of relative loss costs between classes and the actual amounts experienced for policy year 1987 at first report. Two tests of accuracy are shown in this exhibit.

The top portion presents the results of the underwriting test. For this test, indicated ratios of actual to expected losses close to 100% indicate greater overall relative accuracy. The approximate significance of differences is shown as "P[Type II Error]".

Small probabilities indicate a small estimated probability of showing this level of difference assuming that the two distributions are the same. Thus small probabilities can be interpreted as indicating that the specific alternative method is significantly more accurate than the current NCCI method. On the other hand, large probabilities, close to 100%, indicate that the current method is significantly more accurate at predicting relative loss cost differences.

The remainder of the exhibit summarizes mean square error and corresponding Wilcoxon tests. These tests were conducted for various size classes separately and for all classes combined, in the last section. The class size groups are based on the volume of premiums generated by the various classes when ranked for all states and all classes combined.

Smaller mean square errors indicate generally more accurate forecasts of relative loss cost differences than larger ones. We also included a Wilcoxon Statistic to test the difference between the two methods, again by class size and for all classes in a state combined.

A positive Wilcoxon Statistic indicates that the alternative method tended to be more accurate than the current method while a negative statistic indicates the opposite result. Again, probabilities close to 0% or 100% indicate significant differences, the former indicating that the alternative method is more accurate and the latter indicating that the current method is.

Exhibit B-3 provides a similar summary for the consistency tests. In this case we calculated the variances of the ratios of the class rate with an overall average rate based on other

CLASSIFICATION RATEMAKING

states available for that class, year and alternative. Small variances indicate more consistent identification of differences between the state and a larger average.

As with the mean square error and Wilcoxon Statistics in Exhibit B-2, we tested the differences for large, medium and small classes separately as well as for all classes combined. Interpretations of the Wilcoxon Statistics and the corresponding probabilities described in connection with Exhibit B-2 also apply in Exhibit B-3.

Exhibit B-4 summarizes the results of our tests regarding losses in excess of the loss limitation used in classification ratemaking. For each state tested, this exhibit shows the number of classes in each industry group and the number of classes that show differences at the indicated confidence levels.

For example, in Connecticut there are 192 Manufacturing classes. Of these each of 51 were significantly different from the remainder at a 90% confidence level. If the required confidence level were to increase to 95% the number of classes drops to 46, and so forth.

APPENDIX C

CLASSIFICATION RATEMAKING

Appendix C

Example Calculations for Tests of Industry Group Differentials

Exhibits C-1 through C-4 provide examples of the calculations used to derive the results described in part V of this section of this examination report. The basic data, from Appendix A-VII of the NCCI filings, are summarized in Exhibit C-1. These data include the expected losses, indicated losses, ratio of indicated to expected losses and the indicated industry group differentials.

Exhibit C-2 shows the corresponding sums for all of the states for which data were available. The ratios of indicated to expected losses and the indicated industry group differentials are calculated as in Appendix A-VII of the NCCI filings.

Exhibit C-3 shows the calculation of the mean square error for the Colorado filing. Columns (1), (2), (4), and (5) are taken from the first page of Appendix A-VII prepared by the NCCI for the two alternatives. The expected losses assume the same total as the actual losses, but distribute them to the industry groups in the same proportion as the 1987 manual premium. The square errors, difference and corresponding Wilcoxon Statistic are calculated as described in part V.B of this section of this examination report.

Exhibit C-4 shows the calculations for the consistency test. The relativities in column (2) are the relativities to "Overall" in Exhibit C-1 and are the ratios of the Colorado industry group differentials to those in Exhibit C-2. The variances for each industry group are shown as the arithmetic averages on that exhibit and the calculation of the Wilcoxon Statistic is also shown on that exhibit.

APPENDIX D

CLASSIFICATION RATEMAKING

Appendix D

Discussion of Questions Regarding 'F' Classes

This appendix includes an evaluation of current NCCI 'F' class ratemaking methodology and is in direct response to the March 1991 request of the Examination Oversight Committee. Section IIA of this examination describes the current NCCI 'F' class ratemaking procedures in terms of differences between ratemaking for industrial classes and for 'F' classes. The discussion in this appendix addresses some of the major differences and considers some alternatives.

The format is that of question and answer. 'LHWCA' denotes the U.S. Longshore and Harbor Workers' Compensation Act. 'State Act' refers to a state's workers' compensation statutes.

Observations are based upon NCCI documentation and interviews with NCCI personnel. We also reviewed five rate filings: Michigan (1/1/91), Maine (1/1/91), Florida 1/1/90), South Dakota (3/1/91), and Arizona (10/1/88).

QUESTION:

Is it a reasonable alternative to make 'F' class ratemaking more consistent with industrial class ratemaking by deriving an overall rate level change for a state and then allocating the change to classes?

DISCUSSION:

Based upon a review of NCCI methodology and five state rate filings, we conclude that the current approach to 'F' class ratemaking is reasonable. Because the 'F' class financial call experience is not credible for deriving loss ratios and 'F' class experience by individual state is sparse, using an overall rate level change approach for an individual state like the industrial classes is not reasonable.

The ratemaking methodology for 'F' classes uses a pure premium method which derives the rate for each class based upon WCSP data. For industrial classes, the NCCI utilizes a loss ratio approach to identify the overall rate level change which is then allocated to classes using a pure premium method. Financial call experience supports the overall rate level change and WCSP data is used to allocate the overall rate level change to classes.

CLASSIFICATION RATEMAKING

The pure premium approach and the loss ratio approach are both well documented and their equivalence is demonstrated in actuarial literature. Assuming that consistency in methodology is preferable, we considered (1) whether current 'F' class data will support the more consistent approach, and (2) whether the consistent approach will provide indications at least as reasonable as the current methodology.

The NCCI considers the earned premium data in the 'F' class financial calls for policy year and calendar year to be unusable due to data quality problems. This precludes the use of the loss ratio approach for 'F' classes. The NCCI documented attempts to utilize the data between 1978 and 1980, and in 1986, and concluded that carriers were unable to report the requested earned premium and loss information.

Sparse 'F' class data on an individual state by state basis provides low credibility for indicated rate level changes. The NCCI considers the countrywide 'F' class experience in aggregate to be equivalent in volume to a medium-sized state. Thus, except for Louisiana which is the state with the largest amount of data, the volume of 'F' class experience for most states is sparse. A review of five rate filings confirms that observation. For example, for policy years 1982 to 1984, there were a total of only 13 'F' class claims reported in Michigan. For policy years 1984 to 1986, there were a total of only 31 'F' class claims in Maine. Thus, even if accurate data was available to support a loss ratio approach, the indications would be questionable for most states. The use of a countrywide indicated rate level change is not feasible because of the impact of benefits under the different state statutes discussed in the next question.

QUESTION:

Is the calculation of countrywide 'F' class rates a reasonable alternative?

DISCUSSION:

A review of the basic NCCI methodology and five state rate filings indicates that it is not reasonable to derive 'F' class rates (or loss costs) for direct use countrywide. 'F' class rates must be developed on a state by state basis to recognize the impact of benefits under each state's statutes as well as benefits under the LHWCA. For each state, there is a unique mix of loss experience under the State Act and LHWCA. State-specific ratemaking components include benefit levels, assessments, loss adjustment expenses, and payroll limitation.

CLASSIFICATION RATEMAKING

The 'F' class risk is a combination of risk under each State's Act and risk under the LHWCA. Therefore, the rates must reflect that blend. In each state, 'F' class claimants can elect to receive compensation under the State Act or the LHWCA at the time that the claim is reported. Usually, claimants choose the benefits most advantageous at that time. NCCI estimates that for countrywide 'F' class data, approximately 70% of the losses are under the LHWCA because the benefits under the LHWCA are generally higher. However, the proportion can differ greatly by individual state. For example, in Maine, only 32% of the losses are under the LHWCA. In states with much lower state benefit levels, the proportion under the LHWCA is much higher.

Assessment rates differ between states and the LHWCA. The Special Fund assessment rates under the LHWCA are substantially higher than the states' assessment rates. The Special Fund assessments have also increased significantly during the past ten years, primarily driven by second injury claims which accounted for 87% of Special Fund expenditures in federal fiscal year 1987. The current Federal assessment rate of 31.2% is applied to indemnity payments and NCCI estimates that the impact is equivalent to a 24.2% rate on total losses. In 1979, the federal assessment rate was 4.3% but has been above 11% since 1982. In the reviewed state filings, state assessments ranged from 0% to 1.9% of total losses. The impact of assessments depends upon the proportions of affected losses which differ by state as well as the assessment rates.

Benefit levels differ between the State Acts and the LHWCA. The impact of the benefit level difference in each state also depends upon the proportion of losses affected.

In addition, some states mandate their own factor for loss adjustment expenses. Louisiana still has a payroll limitation.

QUESTION:

Is the current use of pure premium indicated by national relativity reasonable?

DISCUSSION:

A review of the documented formulas and methodology and state rate filings indicates that the approach is reasonable. NCCI derives a formula pure premium similar to that calculated for industrial classes. The major difference is the need to reflect the impact of the State Act as well as the LHWCA in the use of a pure premium indicated by national relativity.

CLASSIFICATION RATEMAKING

For a given state, there may be many 'F' classes with no or very low credibility for the state's indicated pure premium. For example, Michigan had only 4 of 16 classes with credibility above 10% in the latest rate filing. Maine had only 2 of 16 with credibility greater than 11%. Therefore, it is important to have some current indications to complement the pure premium underlying present rate. For most 'F' classes, the formula pure premium will be the average of the pure premiums from the national indication and the underlying rate with some relatively small adjustment for indicated state experience, if any.

To efficiently accommodate all of the individual state rate filings, NCCI first aggregates the experience for all states except Louisiana to produce interim pure premiums indicated by national relativity. These interim values contain federal losses brought to the appropriate federal level of benefits and assessments. Losses under each State Act are converted from their state's benefit level to the federal benefit level.

Then, a state's national pure premiums are calculated. The interim national pure premiums are multiplied by factors to reflect the specific impact of losses under the State Act. Conversion addresses state benefit levels, state assessments, the state's loss adjustment factor, and state payroll limitation.

QUESTION:

Should there be provision for trend?

DISCUSSION:

We believe that there should be provision for trend in the 'F' class rate calculations. Medical inflation continues and medical benefits have been increasing as a proportion of total benefits. Indemnity trends should be investigated. The NCCI had already targeted the inclusion of trend as a task to be addressed for the new cycle of rate filings to be completed for 1992.

The 1990 'F' class rate filings incorporated no provision for trend. NCCI concluded that the WCSP trend indications were distorted by major statutory changes in 1984, and the search for alternative sources was postponed because more emphasis was placed on rate filings for the industrial classes. The 1984 changes included capping of the rate of escalation for the first time and elimination of survivorship benefits for spouses of permanent total claimants.

CLASSIFICATION RATEMAKING

It should be noted that beginning in 1990, NCCI reinstated annual 'F' class rate filings after developing a new 'F' class ratemaking system. There had been only one set of 'F' class rate filings between 1984 and 1989 which was the period during which NCCI moved to the Florida location and resources were needed for industrial class ratemaking.

We believe that the 'F' class financial calls can provide some insight into at least the medical trends. NCCI has considered the 'F' class financial calls to be unusable for ratemaking because of data quality problems but we understand that the greatest problem has been with the reported standard premium. Trend indications based upon reported losses will at least permit some evaluation of the use of medical trends for industrial classes in a state. We understand that NCCI is investigating the use of 'F' class financial call data as well as seeking other sources.

QUESTION:

Is the NCCI seeking an alternative source for loss development factors from the fifth report to ultimate?

DISCUSSION:

NCCI is seeking a source of loss development factors from the fifth report to ultimate. In the latest 'F' class rate filings, experience from the District of Columbia's Workers' Compensation Act (DCCA) was used to provide the loss development factors after the fifth report. However, the benefit levels under DCCA ceased to be the same as the benefit levels for the LHWCA in 1982.

We understand that NCCI is investigating the use of 'F' class financial call data and seeking other sources. We believe that the 'F' class financial calls can provide some insight into loss development patterns to at least permit some evaluation of the use of loss development factors derived from industrial class experience in a state.

APPENDIX E

CLASSIFICATION RATEMAKING

Appendix E

Subdivision of the "All Other" Industry Group

As indicated in part VII of this section of this examination report, our analysis of the "All Other" industry group indicated that this industry group could be further subdivided to increase homogeneity and yet with each subgroup having substantial experience. Specifically, an example was discussed showing that the current "All Other" industry group could be divided into an "Office Employees" industry group and an "All Other - Excluding Office Employees" industry group. Exhibits E-1 through E-3 present the first twenty, ranked by payroll volume, of the classes that remain after the exclusion of the "Office Employees" class from the "All Other" industry group. Also shown for informational purposes are the losses corresponding to these classes.

20. 927 - Drugstores	1,448	8.2

NOTES:

- For comparison purposes, the Office Employees class payroll is \$81,801 million, and the corresponding losses are \$174.3 million; the Contracting industry group's payroll is \$18,798 million, and the corresponding losses are \$886.6 million.
- Columns (1) and (2) include manual years 1983 through 1987.

APPENDIX F

CLASSIFICATION RATEMAKING

Appendix F

Summaries of Differences Between Current and Alternative Methods

This appendix contains a series of charts that summarize the differences in final rates between the current NCCI methodology and the specified alternatives considered in this examination. Each chart contains two graphs and three summary statistics while the first is a summary of the states and policy years for which alternate rates were calculated.

The horizontal, or "x" axis of the charts represents various ranges of percent differences between the current and the indicated alternative method, calculated as:

$$\frac{R_{ij}^2 - R_{ij}^1}{R_{ij}^1}$$

Here R_{ij}^1 denotes the final rate for class i in state j using the current NCCI methodology

and R_{ij}^2 denotes the final rate for the same class and state but using the specified alternative methodology.

The bar graph, which is enumerated using the left vertical axis, shows the number of classes having differences in the indicated range. The line graph, which is enumerated using the right vertical axis, shows the total premium volume of those classes. This premium volume is expressed as the rate using the current NCCI methodology times the payroll in the class for the most recent year used in calculating the classification rates.

The three numbers indicated in each graph indicate the square difference index as described in part IV of this section of this examination report, the Wilcoxon Statistic used to test the significance of differences on a class by class basis and an approximate normal probability corresponding to that statistic. Discussions of this statistic can also be found in part IV.

CLASSIFICATION RATEMAKING

Briefly, if the value of the Wilcoxon Statistic shown in the graphs is close to zero, differences between final rates by class would not be viewed as significantly different than zero. Statistics with large absolute values may indicate significant differences. In terms of the approximate normal probabilities, probabilities close to 50% indicate little significance while values close to 0% or 100% indicate significant difference.

The significance of the difference is measured by how close to 0% or 100% the probabilities are. For example, probabilities of less than 5% or greater than 95% would indicate differences significant at approximately the 95% confidence level.

APPENDIX G

CLASSIFICATION RATEMAKING

Appendix G

Calculations Supplied by NCCI

Exhibits G-1 and G-2 summarize the results of calculations performed by NCCI extending our tests of relative accuracy of using five years of experience, as compared with three to six other states, of first report as well as some modifications to those tests. We strongly recommend consulting Section X of this part of this examination report, pages 77 through 79, for a more complete discussion of these additional tests.

By way of summary, we understand that NCCI applied our tests of relative accuracy to first report data in six states for which actual loss data was not available at the time of our primary analysis. These states are Florida, Louisiana, Michigan, North Carolina, Oregon, and Utah. In addition, we understand that NCCI applied these same tests to second report data for the original five states used for this test; Colorado, Connecticut, Illinois, Maine, and Nebraska.

Other tests we understand NCCI performed involved modification to the methodology outlined in this examination report. The first modification removed the adjustment using the ratio of standard to manual premium in our calculations. They also replaced actual losses at first or second report with those losses developed to an expected ultimate level.

Exhibit G-1 presents these additional tests applied to the original five states. Exhibit G-2 shows the results for the six additional states.

Additional Comparisons of Actual vs. Expected Losses

LAW AMENDMENTS

I. INTRODUCTION

The National Council on Compensation Insurance (NCCI) is frequently called upon to estimate the impact of actual or proposed statutory revisions. Furthermore, their methods are sometimes used by consultants to evaluate and comment on proposed legislation. This section of the report will discuss the NCCI methodologies used to determine the rate level changes due solely to actual or potential statutory revisions.

In our analysis, we have separated the types of statutory revisions into two categories: "formula" benefit changes and "non-formula" benefit changes. NCCI defines formula changes as those that can be estimated directly from the use of various tables and distributions, while all other changes are considered non-formula. For use in this report, a formula change will be any benefit revision that involves one or more of the following items:

- Changes in maximum weekly benefit,
- Changes in benefit level as a percentage of gross wages,
- Changes in waiting periods,
- Changes in retroactive periods,
- Changes in escalation rates,
- Changes in medical fee schedules.

All other benefit changes will be considered non-formula. A law change can include some formula components and some non-formula components.

As a historical note, the long term impact of the benefit changes evaluated by NCCI has generally been small. To illustrate this fact, Exhibit 1 provides the countrywide components of rate level changes evaluated by NCCI for the past 25 years, separated into the categories of experience changes and benefit changes. This exhibit which is based on information contained in the NCCI Annual Statistical Report, 1991 edition, (Annual Statistical Bulletin) shows that on a countrywide basis over the past six years,

LAW AMENDMENTS

the benefit changes have been small both in absolute magnitude (an average of +1.1%) and also in relative magnitude (13.2% of the experience average change of 8.4%). In the five years prior to that time, benefit changes were slightly higher ranging from +2.7% to +5.0%, and the experience changes during that time period were much smaller.

In general, over the 25 year history shown, the only time period during which benefit changes were consistently high was the early 1970's. During that period, many states were dramatically increasing their benefit levels in response to the National Commission on Workers Compensation Study.

The benefit changes included in Exhibits 1-3 are only those where NCCI or another rating bureau has calculated the impact. Changes in benefit provisions where the rating bureau has not calculated an impact would not be reflected. For example, changes in administrative systems are generally not evaluated as benefit changes by NCCI. Also, the benefit changes in these Exhibits are based on the rating bureau's original estimate. The effect of changes which are not evaluated by the rating bureau and the difference between the actual benefit effect and the rating bureau's estimate of the effect are eventually reflected as experience changes. For example, some of the large experience changes observed in the mid 1970's may be due to delayed recognition of larger than expected law change effects.

Exhibit 2 shows a distribution of benefit level changes by size over the past 5 years based on information contained in the Annual Statistical Bulletin. Of the 288 benefit changes with effective dates from 1985 through 1989, 240 (83%) were benefit increases or decreases of no more than 2.5%. Only 16 (6%) were increases or decreases of greater than 5%. This indicates that at least by numbers, a large majority of NCCI benefit calculations have been for relatively small amounts over the past five years.

However, this is not to imply that benefit issues are unimportant. For states with perceived problems in their workers compensation systems, these national averages offer little in the way of comfort.

LAW AMENDMENTS

As states focus on workers compensation cost containment, it is important that the methodologies used by the NCCI to estimate the impact of legislative changes on the workers compensation systems are as accurate as possible.

In this section of the report, we will address the following objectives of the RFP:

1. A review of NCCI's procedures for determining the expected loss changes due to revisions in weekly benefits, waiting periods, escalation provisions, and medical fee schedules (Section II.b. Objective 5a).
2. A review of NCCI's performance in analyzing non-formula benefit changes (Section II.b. Objective 5c).
3. Various questions on the Wage Distribution Table including:
 - a. Should the 1973 Standard Wage Distribution Table be Updated? (Section II.b. Objective 5b.)
 - b. Should different wage distribution tables be used for different class groups? (Section II.b. Objective 5d.)

LAW AMENDMENTS

LAW AMENDMENTS

II. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

A. Formula Benefit Changes

Most formula benefit changes depend on tables of distributions of wages, dependency status, type of injury and other factors. Since the tables currently in use by NCCI are based on data from the early 1970's, we tested the sensitivity of results to potential errors in these tables. Generally, the results were not sensitive to variations in the tables. This does not mean that updates are not necessary. First, the use of 1970's tables in the NCCI formulas fosters an appearance of inappropriate methodology which may not always be corrected by the inclusion of documentation as to its reasonableness. Second, the tables are not necessarily accurate for benefit changes outside the norms considered in our sensitivity test. NCCI should consider updating and revising its tables (Section III.B, Page 18). NCCI informed us that soon they will use an updated Wage Distribution Table and that they will annually monitor this table. In addition, they are reviewing other tables. In addition, NCCI should replace its standard rate filing package with a more descriptive summary of the fundamental issues being priced (Section III.C, Page 18).

1. Wage Distribution Tables

Revisions in the weekly minimums and maximums for indemnity benefits are the most common kind of formula benefit change. The most significant factors in the evaluation of those benefit changes are distributions known as "Wage Distribution Tables." Although there is later data available with which to construct alternative wage tables using statewide data, the NCCI generally uses a wage distribution table based on 1973 countrywide data. Based on our tests, pricing effects are relatively insensitive to the choice of wage table (Section V.A., Page 55).

2. Dependency and Other Distributions

Most other distributions used in formula benefit pricing are based on data collected at about the same time as the 1973 Wage Distribution Table. Since then, a large number of social and economic events have occurred that could alter the distributions. However, we have examined the sensitivity of the overall formula

LAW AMENDMENTS

pricing of a change in the weekly maximums and minimums based on changes in family size, dependency status and other factors. We have found the overall pricing effect to be fairly insensitive to these potential changes. Thus, the formula benefit change pricing seems to be working satisfactorily, despite the age of the underlying distributions (Section IV.C.1, Page 46).

However, we recommend that NCCI consider updating duration tables and continue to monitor durations on an ongoing basis. Using a single countrywide table for all states may not be the best way to reflect the impact of changes in waiting periods or retroactive periods (Section III.C.2, Page 25).

3. Medical Fee Schedules

Medical Fee Schedule changes are generally evaluated using a distribution of medical procedures developed in 1967. This distribution is cross tabulated with the fees on the schedule in order to price the effects of changes. However, since 1967, there have been dramatic technological changes in the practice of medicine. For example, some currently commonplace procedures did not exist in the early 1960's. Thus, when a fee schedule is implemented for the first time, or is adjusted substantially, there is a likelihood that the current NCCI methodology will not perform adequately.

Since medical cost containment is an important and timely topic, we believe it is appropriate that NCCI update its distributions and refine its methodologies for pricing medical fee schedules. The current NCCI procedures cannot readily measure the impact of medical cost containment measures (Section III.C.4, Page 36). NCCI has informed us that they will shortly have available data useful for evaluating medical cost containment measures.

4. Relationship of Benefit Changes to Trend

It is essential that the same procedures used in the trend calculation to adjust benefits to current level be used in the evaluation of law amendments. Therefore, changes made to benefit pricing methodology should be consistent with changes made to the benefit on-level calculations in the trend methodology (Section III.C.6, Page 39).

LAW AMENDMENTS

B. Non-formula Benefit Changes

We have developed a classification of 8 categories where we expect non-formula changes to occur in the upcoming years. These are (Section IV.B., Page 41):

- Compensability
- Objective standards for permanent partials
- Changes in compensation for permanent partial
- Changes in rehabilitation programs
- Changes in benefit administration
- Changes to reduce litigation
- Attempts to decrease interdependence of economic conditions (e.g, unemployment) and workers compensation benefits
- Medical cost containment issues

Our recommendations regarding the pricing of non-formula benefit changes are summarized below (Section IV.D., Pages 51):

- Improve the method of identifying law changes significant enough to require the use of non-formula techniques. In some non-formula situations, NCCI appears to apply formula techniques when those techniques are not appropriate. In other more recent cases, NCCI has applied new data sources and new estimation techniques.
- Increase the utilization of state specific information regarding the workers compensation benefit system being analyzed.

LAW AMENDMENTS

- Rely on input from non-actuarial areas in developing pricing models. This would include utilizing experts from other disciplines such as economics, legal claims, etc.
- Develop a data collection model facilitating retroactive review of the effects of major benefit changes. This would include establishment of measures to test the actual versus expected impact of critical elements in the law revision.
- Improve models to measure the effect of changes in benefit administration.
- Develop models that better analyze changes in benefit utilization.
- Improve the explanatory material included with a benefit pricing report.

C. Wage Distribution Tables

Our analysis of updated wage table information indicates that only small changes in the overall pricing would result from its use. However, since wage data will be collected in the future in all states with the new Detailed Claim Information (DCI) system, we recommend that NCCI update its wage distribution tables and consider the use of statewide tables, once the revised DCI data is available (Section V.A., Page 56).

Our analysis showed that use of separate wage distribution tables by classification group would have very little effect on the overall pricing.

However, use of separate wage tables for each classification group could substantially affect the rates by classification group under certain circumstances. We recommend additional research into the use of separate wage tables for classification ratemaking (Section V.B., Page 59).

LAW AMENDMENTS

III. REVIEW OF FORMULA TYPE CHANGES

NCCI has developed a series of tables and statistical distributions that are used to evaluate all benefit changes. While some benefit revisions can be estimated directly from the tables and distributions, other changes require the use of additional data. This has given rise to the use of the terms "formula" benefit changes and "non-formula" benefit changes. A law change can include some formula components and some non-formula components.

In this section, we will discuss:

- A. Basic Pricing Parameters
- B. Data and Tables Used
- C. NCCI Formula Pricing Methodology

A. Basic Pricing Parameters

The NCCI categorizes claims by type of injury as follows:

- Medical Only
- Temporary Total
- Permanent Partial (Major and Minor)
- Permanent Total
- Death

Each of the last four categories can give rise to both medical losses and indemnity losses. In all benefit pricing calculations, separate estimates are performed by type of injury for indemnity, whereas one overall calculation is performed for medical. These separate effects are then weighted together based on the percentage of total losses represented by each type of injury. The weights are determined based on data obtained from the Workers Compensation Statistical Plan (WCSP).

LAW AMENDMENTS

For reporting purposes under the WCSP, each insurer assigns each claim to exactly one of the five categories listed above. As the injury progresses and as new information is received, the category (status) of a claim may change from report to report.

Uniform classification of injuries among insurers and across states is important. Obtaining such uniformity is complicated because workers compensation statutes may classify injuries using varying definitions of categories. Some states classify benefits as total or partial, but do not categorize their permanency. Other states have a permanent impairment benefit, but not a permanent partial benefit.

To obtain uniformity, WCSP gives instructions as to how to classify injuries. According to WCSP, a permanent partial claim is:

- "1. Any permanent injury which does not involve permanent total disability.
2. Any temporary injury which satisfies one of the following criteria:
 - a. The duration of disability benefits exceeds or is expected to exceed one full year. No loss is to be reported as temporary total if the duration of total disability exceeds or is expected to exceed 52 weeks.
 - b. A lump sum settlement is made or, in the judgement of the carrier, will be required to settle future benefits.
 - c. The extent of liability for future payments cannot be determined."

In nearly all states, permanent partial benefits form a significant block of the total benefit dollars. Exhibit 3 shows that the percentage of total indemnity costs contributed by permanent partial injuries has been increasing for nearly all states.

LAW AMENDMENTS

The categorization of permanent partial claims into major and minor is handled internally by NCCI based on the size of the incurred indemnity benefits for a particular claim. Claims with indemnity costs below the cutoff value are assigned to minor, while claims at or above the cutoff are assigned to major. The cutoff amount is known as the "critical value". In most formula benefit change situations, the difference between permanent partial major and permanent partial minor has little significance for benefit pricing even though NCCI separately estimates cost effects for both categories. Issues relating to the classification of claims into permanent partial major and permanent partial minor are discussed further in Appendix A.

B. Data and Tables Used

The key elements of NCCI's formula pricing are (1) the features of the old and new laws and (2) a series of tables. The important features of the laws, and the categories of injuries that are typically affected are shown in Table 1.

<u>Variable</u>	<u>Table 1</u>				
	<u>Benefit Affected</u>				
	<u>Fatal</u>	<u>PT</u>	<u>PPD</u>	<u>TTD</u>	<u>Medical</u>
% Change in Compensation Rate	+	+	+	+	
Min/Max Weekly Benefit	+	+	+	+	
Maximum Aggregate Benefit	+	+			
Duration of Benefit	+	+	+		
Burial	+				
Remarriage/Dowry	+				
Special Funds	+				
Social Security	+	+			
Escalation	+	+		+	
Waiting/Retro Period				+	
Minimum Payment for Dependent	+	+			
Additional Dependents	+				

LAW AMENDMENTS

Note: + means that the variable often or always needs to be examined, but it may not be required for pricing. A blank indicates that the variable is not typically required for pricing. PT represents Permanent Total, PPD is Permanent Partial, TTD is Temporary Total.

The most important tables used by NCCI in benefit evaluations are the following:

1. 1973 Standard Wage Distribution Table
2. Temporary Total Accident Distribution Table
3. Injury Tables (Separate tables exist for Fatal, Permanent Total and Permanent Partial.)
4. Countrywide Medical Fee Frequency Distribution Tables
5. Life Annuity Tables and Discount Rates
6. Widow's Age and Remarriage Rates

Also important are:

7. Statewide Average Weekly Wage (SAWW)
8. Social Security Offset

These tables and issues related to the SAWW and Social Security are discussed below:

1. 1973 Standard Wage Distribution Table

This table shows a distribution of wages around the average wage. This table was derived based on 1973 data and appears in Exhibit 4.

The 1973 Standard Wage Distribution Table (Wage Distribution Table) is used to estimate the average weekly benefit for injured workers under the workers compensation benefit structure. The table displays the percentage of total workers and the percentage of total wages at various relativities to the statewide average wage.

LAW AMENDMENTS

For example, the table shows that 58.4% of the workers earn less than 1.0 times the statewide average weekly wage. (See Exhibit 4, Column A at R = 1.0). The aggregate wages of these workers amount to 40.9% of the total wages in the state. (See Exhibit 4, Column B at R = 1.0).

The distributions in the Wage Distribution Table are used to calculate the average weekly benefit under both the new and old benefit structures, for each type of injury, and within each type of injury for each component of the benefit.

From the Wage Distribution Table, we can identify three intervals for each percentage rate of compensation. The first interval includes all workers earning wages so small that their average weekly benefits, calculated as a percentage of their average weekly wage, would be below the statutory minimum. Their actual compensation will be higher than the statutory percentage compensation rate.

The second interval includes workers earning average weekly wages within the constraints of the minimum and maximum allowable benefit and any aggregate limits applicable. Their compensation will equal the statutory percentage compensation rate times the actual wage.

The third interval consists of workers whose average weekly benefits, calculated as a percentage of their average weekly wage, would be larger than the statutory maximum. Their compensation will equal the maximum weekly benefit and their compensation will be less than the statutory percentage compensation rate.

Using the wage table, NCCI can calculate (1) the average weekly benefit in each interval and (2) the percentage of the total statewide workers in each interval. Then, the statewide average weekly benefit considering the statewide average weekly wage and minimum and maximum weekly benefits is calculated as the average of the benefits in each of the three intervals described above. This calculation appears in numerous areas of the benefit calculation formula for each component of the benefit structure.

Exhibit 5 shows a simplified example of calculating the average weekly benefit.

LAW AMENDMENTS

NCCI performs a slightly different (although equivalent) calculation than we have described. Instead of calculating the average weekly benefit in each interval, they instead calculate the "effective" average weekly wage that results in the statutory benefit for each interval. By weighting together the effective average weekly wage in each interval, NCCI calculates a "Limit Factor", which is applied to the statewide average weekly wage. The Limit Factor times the statewide average weekly wage times the benefit percentage rate yields the statewide average weekly benefit. The Limit Factor indicates the percent of wages subject to the statutory benefit rate. The change in Limit Factor could also be used to measure the change in subject wages when the statutory benefit rate is changed.

The wage table is the single most important table that affects the formula benefit calculations. It will be discussed and analyzed in more detail in Section V.

2. Temporary Total Accident Distribution Table

This table (Exhibit 6) is used to estimate the impact of changes in waiting periods (the number of days a worker must be disabled before indemnity benefits begin) and retroactive periods (the number of days a worker must be disabled before indemnity benefits are paid retroactively from the first day of disability).

The table was derived from a study of disability durations conducted in the early 1970's.

3. Injury Tables

This series of tables displays various distributions and details for fatal, permanent total and permanent partial claims. The current injury tables were developed via a special call for information issued to insurance carriers in the early 1970's.

a. Fatal Disability Table

This table (Exhibit 7) displays a distribution of dependency status and provides the average dependent age used to value benefit changes. The fatal injury table includes the number of cases (i.e., frequency), the type of person receiving compensation (e.g., none, widow alone, widow with child(ren),

LAW AMENDMENTS

orphan(s), parent(s), sibling(s) and others), the average number of dependents for each case, the computed average arithmetic age and the average pension age.

The column labelled average arithmetic age is used in the valuation of benefit provisions limited to a specified duration or subject to a maximum aggregate amount payable; the column labelled average pension age is used in the valuation of benefit provisions equivalent to a life annuity.

b. Accident Distribution - Permanent Total Disability Table

This table (Exhibit 8) displays a distribution of part of body injured, a distribution of ages, and a distribution of body part and average age.

c. Major Permanent Partial Disability Table and Minor Permanent Partial Disability Table

These tables (Exhibit 9 for Major and Exhibit 10 for Minor) display a distribution of part of body injured, separately for scheduled injuries and "other" (non-scheduled) injuries. For each body part, the percentage loss of use, the average healing period, and the average age of the injured worker is displayed.

A scheduled injury is an injury that is specifically listed in the statute along with a specific benefit level. The definition of a scheduled injury will vary by state depending on what specific body parts are enumerated in the statute. For scheduled injuries, loss of use is expressed as percent of the particular member affected. For non-scheduled injuries, loss of use is expressed as a percentage of the whole man. For purposes of law change evaluations, the percentages of loss of use of a particular member (as expressed for scheduled injuries) can be converted to percentages of a whole man based on standards such as the "American Medical Association Guides to the Evaluation of Permanent Impairment."

LAW AMENDMENTS

Evaluating injuries as a percent of the whole man is a phenomenon we expect to see more frequently in future legislation. This issue is discussed further in Section IV.

4. Countrywide Medical Fee Frequency Distribution Tables

These tables (Exhibits 11 and 12) are used to evaluate medical fee changes. Exhibit 11 displays a frequency distribution by medical procedure code and Exhibit 12 displays an excerpt of definitions of some of the codes. The medical procedure tables are based on studies conducted in the 1960's. Clearly, the use of such an old distribution is a cause for concern since there are medical procedures in common use today that did not even exist 20 years ago. This issue, and the methodology utilized for pricing medical fee changes, will be discussed in a later section.

NCCI treats the establishment of a schedule, when there is none in effect, as a non-formula change.

5. Life Annuity Tables and Discount Rates

The annuity values are based on the United States, 1979-81 Life Table for the Total Population (for injured workers) and Life Table for Females (for spouses). (Copies are included in Appendix B.) Tables are prepared with interest and escalation rates that may vary from state to state. For many states, NCCI uses a 3.5% interest rate, based on the 3.5% statutory discount rate that at one time was in effect for most states. The escalation rate depends on the statutory provisions of the workers compensation law.

The use of an interest rate in the benefit pricing is not intended to impact the overall rate level calculations. The overall rate level is based on projected undiscounted aggregate financial data for loss projections and a profit provision that implies a treatment of investment income that varies among the states.

The use of a constant 3.5% interest rate is a convenience to simplify the benefit calculations. The cost to insurers of providing annuity benefits depends on a complex set of considerations including the cost of capital, income taxes, required surplus, and liquidity. The actual rate used has little impact for formula changes. The issue could be significant in non-formula situations. Finally, if a state converted from non-

LAW AMENDMENTS

escalating benefits to escalating benefits (or vice versa) the effect could be significant and may need to be treated as a non-formula change.

6. Widow's age and Remarriage Rates

The age distribution of widows alone and widows with child(ren) along with their expected remarriage rate is based on the NCCI 1979 Remarriage Tables. This table was based on remarriage data from the 1930's to the 1970's. (Copy is included in Appendix B.)

7. Statewide Average Weekly Wage

Workers compensation systems generally use a statewide average weekly wage (SAWW) to define benefit parameters (e.g., the minimum and maximum weekly compensation benefits). This SAWW is determined by a state agency, typically the Department of Labor. In Texas, for example, the SAWW for statutory purposes, is based on the average weekly wages for manufacturing production workers as determined by the Texas Employment Commission.

In the NCCI benefit evaluation process, NCCI also needs a SAWW which estimates the average weekly wages for workers compensation claimants. NCCI estimates the SAWW for all private sector non-agricultural employment from the Bureau of Labor Statistics "Current Population Survey" (CPS) data. NCCI updates its SAWW annually.

Differences between the NCCI SAWW (used to estimate the average claimant wage) and the state's SAWW (used to define benefit levels) are to be expected. The important fact to note is that the maximum benefit is tied to the statutory SAWW, not the NCCI's SAWW.

8. Social Security Offset

Several state laws provide that the payment of social security benefits acts to reduce workers compensation benefits. These offsets will apply only to permanent total benefits or to fatal benefits. The average social security benefits that a worker or his family are entitled to depend on the worker's status (i.e., disability or survivorship / retirement) and the dependency distribution. The rules controlling the calculation of

LAW AMENDMENTS

the social security benefit are complex and NCCI attempts to estimate the proper social security benefit due to a worker based on the worker's age, dependency status and a history of the average weekly wage in the state.

Most of the tables discussed above, in Sections 1-8, are derived from data from the 1970's, or even earlier. This leads to the appearance that benefit pricings will be inaccurate due to the use of outdated information. Although, this is not generally the case, NCCI should consider updating and revising its tables.

C. NCCI Formula Pricing Methodology

The first item NCCI sets forth in their pricing is a comparison of benefits under the old law and the corresponding benefits under the new law. A sample of this comparison is shown in Exhibit 13 (based on a benefit change in Nebraska). These summaries are so concise, that it is often difficult for the outside reader to ascertain the important elements. We believe that the summaries produced by NCCI should be replaced by a more descriptive summary of the fundamental issues being priced.

A typical NCCI filing then proceeds to evaluate the law change effect on each type of injury. In this section, we summarize NCCI's analysis. For ease of reference, our discussion will follow the format of Exhibit 13:

1. Fatal Benefits
2. Total Disability Benefits (Permanent Total or Temporary Total)
3. Permanent Partial Benefits

In addition, we will discuss two other topics:

4. Medical Fee Schedule Changes
5. Escalation

LAW AMENDMENTS

1. Fatal Benefits

Based on the 1990 NCCI Annual Statistical Bulletin, the percent of incurred benefits attributable to fatal cases ranges from a low of 0.6% in Hawaii to a high of 7.6% in South Dakota, with most states falling in the 1-4% range. Therefore, fatal benefits comprise a small percentage of total benefits, generally less than any other benefit type. However, the fatal benefit cost elements being evaluated tend to be relatively objective, so NCCI will use a detailed model to evaluate the cost changes, despite the likelihood that the rate level impacts will be minor.

The cost of fatal benefits, in most states, are determined by some or all of the following components:

Fatal Benefits Statutory Components

- % Rate of Compensation,
- Minimum/Maximum Weekly Benefits,
- Maximum Aggregate Payable,
- Duration of Benefits,
- Burial Allowances,
- Remarriage Awards,
- Special Fund Assessment,
- Social Security Offset,
- Escalation of Benefits.

To evaluate the cost of fatal benefits pre and post law, the NCCI procedure uses the following data and information:

Data and Information Used

- the Statewide Average Weekly Wage (SAWW),
- Wage Distribution Table,
- Accident Frequency and Average Age by Dependency,
- Average Age of Widows and Expected Remarriage Rates,
- Average Social Security Weekly Benefits,
- Life Annuity Tables.

LAW AMENDMENTS

Our goal is to describe and comment on the reasonableness of the general methodology used by NCCI to evaluate the cost of fatal benefits due to the statutory provisions listed above.

a. Description of Methodology

The cost of fatal benefits is generally divided into (1) the cost of dependency, (2) cost of burial, (3) cost of remarriage and (4) cost of special funds. We describe the process in general terms below. A more detailed summary of a sample NCCI fatal benefit calculation is included as Appendix B.

(1) Cost of Dependency

The valuation of dependent benefits is determined by the present value of the applicable average (weekly) benefits payable over a specified time duration defined by law. For example, in the case of widows, the duration is generally for life or remarriage while a duration for a dependent child may be to age 18, or 21 if a student.

An annuity value is used to calculate the present value of a unit of benefit payable for the appropriate duration. The annuity value considers the type of benefit (e.g., deferred annuity or annuity certain) and the duration of benefits (e.g., life or term, escalated or unescalated).

In some states, there is a maximum dollar limit to the fatal indemnity benefits. This dollar limit is then used to adjust the estimated duration of the life annuities.

An annuity certain, which is used for evaluating benefits for children, implies the benefits are certain (definite) for the eight year duration. Apparently NCCI considers the probability of the child not surviving too low to reflect in this benefit calculation. The probability of the last-survivor status failing is small, and we concur that it would be a pointless complication to reflect this detail here.

LAW AMENDMENTS

(2) Cost of Burial

Burial benefits are based on the number of fatal cases and the burial allowance under the statutory law amendment both pre and post law.

(3) Cost of Remarriage

The statutory benefit for remarriage is generally a lump sum award for a specified number of years (e.g., two years). In some states, such as Colorado, this benefit applies only if there are no dependent children. Therefore, the remarriage benefits are computed based on the average of the present value of benefits if widows remarry (1) without dependent child(ren) and (2) with dependent child(ren). The later benefit value is calculated as if remarriage were delayed eight years. The eight year offset represents the period of time for a child of average age (10 years old) to reach age 18, when benefits for dependent children cease.

(4) Cost of Special Funds

The special fund assessment is usually based on the number of non-dependency fatal cases and the special fund dollar amount required under the statutory law amendment both pre and post law.

b. Analysis and Comments

While the composition of the typical family may have changed significantly since the early 1970's, the effect on the benefit change valuations may be reduced because the NCCI method uses the same family structure before and after the benefit change.

To test this hypothesis, we assumed a new dependency distribution and new remarriage rates and repriced a sample fatal benefit change using the standard NCCI distribution and our assumed test distribution (Exhibits 14 and 15). As expected, the effect on the fatal category is not significant.

LAW AMENDMENTS

Even if the effect were significant on fatal cases, indemnity benefits for fatal cases are a small percentage of the total benefit dollar, so even a substantial inaccuracy in the fatal calculation would have a small effect on the overall benefit pricing.

2. Total Disability Benefits (Permanent Total and Temporary Total)

The cost of total disability benefits, in most states, is determined by the following components:

Total Disability Benefits Statutory Components

- % Rate of Compensation,
- Minimum/Maximum Weekly Benefits,
- Duration of Benefits,
- Waiting Period/Retroactive Period,
- Minimum Benefits Payable (if dependents),
- Social Security Offset,
- Additional Benefits (if dependents).

The significance of the individual components will vary from state to state.

This section provides an overview of the NCCI procedures used to evaluate changes in permanent total disability benefits and temporary total disability benefits. Appendices C and D provide detailed examples of the NCCI calculations for permanent total and temporary total benefits, respectively.

With the exception of Delaware, New Mexico, and Pennsylvania, permanent total indemnity benefits in most states form a small percentage of the total benefit dollar (i.e., less than 5% in most cases).

Permanent total disability claims are evaluated on the basis that the injured worker is unable to engage in any gainful employment due to the injury. Depending on the state, permanent disability status may be awarded based on the seriousness of the injury, the loss of earning capacity, the ability to find employment and other factors.

LAW AMENDMENTS

Most states also have a presumptive permanent total disability status if the injured worker suffers a specific set of injuries tabulated in the statute.

Temporary total disability implies the worker is expected to return to full time work after a disability period.

a. Description of Methodology

(1) Permanent Total Disability

In the NCCI model, the cost of permanent total disability benefits depends on the state average weekly wage, the duration of benefits, social security offsets, if any, and other statutory benefits. In addition, the duration of benefits may also depend on the number and age of dependents.

The calculations are detailed since they reflect many factors, including the following, as relevant to a particular state:

Life annuities,

Deferred annuities,

Escalation,

Social Security Disability and Retirement Benefits (which have their own set of complex underlying formulas).

NCCI's formula methodology typically does not attempt to measure changes in the frequency of permanent totals that may result from the benefit change. That effect, if any, would be a non-formula change.

The accident distribution by age and dependency used for the evaluation of permanent total disability benefits is based on the Workers Compensation Injury Table for Fatal Disability (Exhibit 7).

LAW AMENDMENTS

Where appropriate, the benefits may be offset by social security benefits.

(2) Temporary Total Disability

The cost of temporary total disability benefits depend on the statutory waiting period (i.e., the minimum days lost before workers compensation benefits become available), the retroactive period (i.e., the minimum days lost after which the worker can recoup the disability benefits for the waiting period), the state average weekly benefits and the total days of disability.

In a small number of states, temporary total benefits may be subject to escalation, if the period of disability is long enough. For example, in Maine, total disability is subject to escalation on the third anniversary of the date of injury. Also, Connecticut escalates total disability on the anniversary of the injury date.

b. Analysis and Comments

(1) Permanent Total Disability

As with fatal benefits, permanent total indemnity benefits in most states form a small percentage of the total benefit dollar, so the overall formula pricing is relatively insensitive to the accuracy of the permanent total pricing. Moreover, by using the same benefit duration before and after the benefit change, the table accuracy does not significantly affect the results. Therefore, the key component in the accuracy of the pricing is the performance of the wage tables.

(2) Temporary Total Disability

The distribution of durations impacts the pricing only if there is a change in waiting period or retroactive period. This is an infrequent occurrence. Otherwise, the same distribution of durations is assumed to apply under both the old law and the new law. Therefore, as with

LAW AMENDMENTS

the other injury types studied so far, the key component of the formula benefit calculation is the wage table.

The frequency of short duration cases is based on estimates since NCCI only captures data when there has been a claim (i.e., when the waiting period has been exceeded). Since waiting periods vary by state, there is still some actual data available to price short term disabilities. However, the data for short term durations is based on the smallest sample size and is therefore subject to the greatest uncertainty. NCCI should be able to update the duration tables based on DCI data. The duration of temporary total cases is affected by a number of factors including the following:

- i. Extent of injury,
- ii. Effectiveness of medical treatment,
- iii. Incentives for return to work.

Forces that may have changed these factors, since the duration tables were constructed in the early 1970's, include the following:

Changes in the industrial mix (i.e., changes from manufacturing to service based economy),

Advances in medical technology,

Changes in family composition and other demographic factors,

Changes in economic cycles.

We recommend that NCCI consider updating the duration tables and continue to monitor durations on an ongoing basis. It seems likely that the duration of claims will be influenced by the waiting periods and retroactive periods in the state. For example, if a state has a 21 day retroactive period, it seems likely that there will be a cluster of

LAW AMENDMENTS

disabilities lasting exactly 21 days, while a state with a 14 day retroactive period would have its cluster at the 14 day point. Therefore, using a single countrywide table in all states may not be the best way to reflect the impact of changes in waiting periods or retroactive periods.

One of the goals of a workers compensation system is to mitigate the hardship of loss of wages when a worker is injured. This goal is balanced by an alternative aim which is to speed the return to work. Most workers compensation systems attempt to balance these goals by paying the worker 66 2/3% of his pre-injury wage, subject to minimums and maximums that vary by state.

The 66 2/3% benefit is tax free and therefore the worker is receiving a higher percentage when the benefit is compared to his net wages (take home pay). If the workers compensation benefit is above or close to the pre-injury take home pay, then the worker may be financially better off collecting workers compensation than returning to employment. Thus, the level of workers compensation benefits affects the incentives for return to work.

When there is a significant change in the average weekly benefit, the incentives for return to work are likely to be modified. This issue is commonly referred to as "utilization". Utilization deals with both the frequency issue (i.e. changes in the number of filed claims) and the duration issue (i.e. changes in the length of time out of work).

The NCCI procedure does not normally include utilization adjustments. However, when there is an increase of more than 5% in the wage replacement rate, the NCCI procedure is to include a factor to reflect increased utilization. Increases of this magnitude were common in the 1970's and were uncommon in the 1980's, but a number of states have recently considered significant increases in temporary total benefit levels. It would be desirable for the NCCI to have better tools available to study this issue. The topic of utilization will be discussed more in Section IV.

LAW AMENDMENTS

3. Permanent Partial Benefits

Permanent partial benefits form a significant block of the total benefit dollars in most states. The percentage ranges from approximately 30% to approximately 70%. Permanent partial indemnity benefits form the largest percentage of total indemnity benefits in all states. Due to the wide variation in the types of benefits contained in the permanent partial benefit package, this area is the most difficult to price under a formula structure.

The definition of a permanent partial injury varies by state. While many states do not use the term "permanent partial" in their statutes, those states do provide additional benefits to workers, who after a return to work, still exhibit residual impairment because of the work related injury.

The process of adjudicating the existence and/or degree of a residual impairment varies by state. The process may involve the courts and/or administrative adjudicators. Impairments may be assessed using doctors retained by each party to the dispute, or by using an independent medical examiner, or both of these. In practice, each state is somewhat unique in terms of its adjudication process. When states are considering revising their workers compensation systems, the issue of how to determine eligibility and impairment is frequently raised. NCCI's models do not now address the cost effects of different procedural and adjudicatory approaches.

NCCI segregates permanent partial injuries into major permanent partial and minor permanent partial. In the sections below, we outline the methods that NCCI uses to price a law effect for major permanent partial and for minor permanent partial. Finally, we describe some considerations when the "critical values" used to distinguish major and minor for permanent partial injuries are not current.

Benefits for major permanent partial and minor permanent partial injuries can usually be divided into two parts: healing period and permanent partial disability benefits. The permanent partial disability benefits are further subdivided into scheduled injury benefits and non-scheduled injury benefits.

LAW AMENDMENTS

During the healing period, the worker is totally disabled and receives the statutory total disability benefits. Once a permanent partial injured employee is able to return to some gainful employment, the employee may have diminished earning capacity and/or diminished bodily functions. The permanent partial award amount is the compensation for diminished earning capacity and/or diminished bodily functions.

Benefits for diminished bodily functions are usually classified as either scheduled or non-scheduled benefits. Scheduled benefits relate to injuries specifically listed in the individual state workers compensation statutes with specific benefits. For example, loss of use of an arm may entitle the worker to 100 weeks of benefits at 66 2/3% of the worker's average weekly wage subject to the statutory minimums and maximums.

Non-scheduled injuries are those permanent partial injuries which do not specifically appear in a state's schedule of injuries. These are compensated based on either wage loss, loss of earning capacity, some type of impairment rating schedule, or other means.

Finally, some states have additional benefits for permanent partial injuries, for example, vocational rehabilitation benefits. Some states offer both an impairment benefit and a wage loss type of benefit.

Critical values are dollar amounts that NCCI uses to distinguish permanent partial major claims from permanent partial minor claims. (Critical values are discussed in more detail in Appendix A.) These critical values have not kept pace with inflation. Thus, injuries that were once considered minor and were used to generate the distributions in the injury table for minor injuries, could currently be classified as major. This would cause a problem when calculated benefit changes are significantly different for major and minor permanent partial injuries. Based on benefit changes in all states from 1985-1989, we observed only four cases out of 288 benefit changes where the difference between the benefit change for permanent partial major exceeded the change for permanent partial minor by more than 4.6%. In those cases, solutions for dealing with the problem include the following:

- Calculate a combined effect for major and minor using combined injury table distributions. This approach has been followed by NCCI in some states (e.g., Colorado, Florida, New Mexico, Rhode Island and Texas).

LAW AMENDMENTS

- Estimate the effects on major and minor by the use of external data which reflects the actual experience as reported.

NCCI has a process for updating critical values which will eventually eliminate this issue. The process involves updating critical values by 10% per year until they reach the indicated amount based on a 1989 study which adjusted the original 1966 critical values for subsequent benefit changes and cost level changes. (See Appendix A for more details.)

a. Description of Methodology

For benefit change valuation purposes, NCCI generally segregates the benefits due to an employee into two categories, the "healing period" and the permanent award. The permanent award is further divided into two components. In this section, we will describe the standard NCCI methodology for calculating the effect of a law change on each of these three parts separately, that is, permanent partial scheduled benefits, permanent partial non-scheduled benefits, and healing period benefits.

The key components of the NCCI valuation are presented in the following table:

LAW AMENDMENTS

(1) Permanent Partial Scheduled Injury Benefits

% rate of compensation for schedules permanent partial benefits,
minimum/maximum weekly benefits for scheduled permanent partial benefits,
duration of benefits for scheduled permanent partial benefits,

(2) Permanent Partial Non-Scheduled Injury Benefits

% rate of compensation for non-schedules permanent partial benefits,
minimum/maximum weekly benefits for non-scheduled permanent partial benefits,
duration of benefits for non-scheduled permanent partial benefits,

(3) Healing Period Benefits

% rate of compensation for healing period,
minimum/maximum weekly benefits for healing period,
duration of benefits for healing period,

(4) Other

Other benefits, such as rehabilitation, if any.

LAW AMENDMENTS

A discussion of these components follows:

(1) Permanent Partial Scheduled Injury Benefits

To calculate the monetary effect of a law amendment on scheduled injuries, NCCI tabulates the following information on a pre and post law basis:

- i. Distribution of injuries by type.
- ii. The number of weeks of compensation payable under the statute, by injury type.
- iii. The state average weekly benefit cost for the type of injury.

The product (i)x(ii)x(iii) would give an estimate of the monetary effect pre and post law change.

The actual implementation of all these calculations involves a significant amount of detailed analysis. A complete description of the methodology appears in Appendix E, Part A.

If the only law change is a revision in the weekly minimums and maximums, then the number of weeks of compensation payable would be the same under the new law as under the old law. In such a simplified situation, the only data needed could be the percentage of benefits attributable to the schedule and the percentage attributable to the healing period.

However, in the sample state shown in Appendix E, Part A, more detail is needed. The scheduled permanent partial benefits have varying percentage compensation rates, so that a breakdown of the percentages for the healing period and a breakdown for each level of permanent

LAW AMENDMENTS

partial benefits is needed. The degree of detail required depends on the nature of the law change.

(2) Permanent Partial Non-Scheduled Injury Benefits

The calculation of benefits for permanent partial non-scheduled injuries is very similar to the calculation for scheduled injuries, in that NCCI uses an estimate of the number of weeks of benefits that are payable and an estimate of the average benefit. In a "wage loss" state NCCI must also estimate the average wage loss for a person who sustains a permanent partial non-scheduled injury. NCCI estimates that a 40% wage loss reduction applies for major permanent partial injuries and a 25% wage loss reduction for minor permanent partial injuries. Additional details on the permanent partial non-scheduled benefit calculation are contained in Appendix E, Part B.

(3) Healing Period Benefits

The calculation of the cost of healing period benefits is also very similar to the calculation of the cost of scheduled benefits. NCCI separately estimates a duration of healing period benefits and an average cost of healing period benefits. Typically, NCCI assumes that the duration of healing period benefits will be the same under the "old law" and the "new law", while the average cost of healing period benefits will change. Details underlying this calculation appear in Appendix E, Part C.

(4) Other

If other benefits are due, NCCI estimates their cost based on the statutory provisions.

b. Analysis and Comments

NCCI's permanent partial benefits calculation are typically based on the following tables and assumptions:

LAW AMENDMENTS

- i. Injury Table of major permanent partial injuries.
- ii. 1973 Standard Wage Distribution Table.
- iii. Assumption that the percentage of wage loss is 40% for major permanent partial and 25% for minor permanent partial for non-schedules injuries.
- iv. 1979 Total Population Annuity Table with interest rate of 3.5% and an escalation rate of 0.00% per annum. (Used to obtain annuities for non-scheduled benefits.)

Typically, the average weekly benefit is the only component that is changing from the old law evaluation to the new law evaluation. The effect of this change is measured by use of the 1973 Wage Distribution Table. The other three items in the list above are used to calculate the weights to be applied to various components that have changes in average weekly benefits from the old law to the new law.

A number of steps in the calculation use present value calculations. The standard NCCI benefit calculation displays little documentation of how the present values are calculated.

As we noted for the injury types previously discussed, the most significant factor in the formula benefit pricing for permanent partial is the wage table calculation. Generally for other components, the same distributions are applied both before and after the benefit change. Therefore, the calculated effect is relatively insensitive to the distributions used.

There is little empirical data on non-scheduled permanent partial benefits. Therefore, a great deal of reliance on the assumptions regarding wage loss and duration of benefits is necessary. These assumptions may not be critical for formula benefit changes, since the assumptions only impact the weights for various weekly benefits. More analysis is needed for a non-formula benefit change.

LAW AMENDMENTS

4. Medical Fee Schedule Changes

There are two types of medical fee schedules in use. The first kind lists each procedure and assigns it a dollar value. The second kind is known as a relative value schedule. Here, each procedure is assigned a number of units, which reflect the relative cost of the procedure. A "conversion factor" is used to convert the units to dollars. Some states have a schedule reflecting both absolute dollars for some kinds of procedures and relative values for other procedures.

a. Description of Methodology

Two kinds of pricing will be required in considering medical fee schedules: (1) pricing the initial implementation, and (2) pricing changes to the fee schedules. In this section, we will only discuss the pricing of medical fee schedule changes. NCCI regards (and we concur) that the implementation of a medical fee schedule is a non-formula benefit change.

NCCI uses its distribution of medical procedures (Exhibit 11) and compares that to the procedures in the fee schedule. All procedures that appear in both are called "matchable items." Procedures that appear in the state's medical fee schedule, but not in the NCCI table, are known as non-matchable. When there is a change in a medical fee schedule, the percentage effect on non-matchable items is assumed to be the same as for matchable items. Based on sample data we reviewed, matchable items in two states were 73% and 77% of the total cost of fee schedule items. (What is matchable and non-matchable will vary by state.)

Exhibit 16 shows examples of the material included in typical NCCI rate filings for pricing a medical fee schedule change. There is relatively little detailed support in the filing material. Given the level of detail provided for the indemnity formula benefit calculations, it would be appropriate to display the frequency and cost distributions under the old medical fee schedule and the new medical fee schedule.

LAW AMENDMENTS

The effect of the medical fee schedule is then weighted with other medical costs and hospital costs to generate an overall percentage change. (Exhibit 16) These weights are based on a countrywide analysis.

b. Analysis and Comments

The technique for evaluating medical fee schedule changes is straightforward. That is, tabulate the counts and amounts of procedures under the old cost structure, and then perform the same evaluation under the new cost structure. The key to correct pricing, therefore, lies in using the correct distribution of procedures. The NCCI frequency distribution derived in the 1960's is substantially out of date. For example, a CAT Scan is a well known and expensive procedure that is often used today, but did not even exist in the 1960's.

The move towards newer and more expensive technologies is often cited as a factor causing medical costs to rise faster than the overall rate of inflation. Future efforts in controlling rising workers compensation costs are likely to be directed at medical cost containment. The NCCI law change data base seems incapable of measuring this kind of effect.

If a medical fee schedule is revised in order to keep up with overall cost level increases, then the benefit effect calculation is not sensitive to the distribution used. For example, Exhibit 17 shows a medical fee pricing where all conversion factors increased by 9%. In such a simple situation, a distribution is not even needed. However, if a medical fee schedule is revised in a non-uniform manner, then valuation accuracy depends on having an accurate distribution of the majority of procedures.

The current NCCI standard distribution, which is substantially out of date will not meet this goal. NCCI is attempting to revise their distribution using data obtained from medical auditing firms. In the meantime, they continue to use it in most states.

A problem cited with some fee schedules is that changes in utilization of medical services can defeat the cost controlling mechanisms of the fee

LAW AMENDMENTS

schedule. NCCI's pricing mechanism also appears incapable of capturing this phenomenon.

Finally, when a fee schedule is installed for the first time, accurate pricing requires a distribution of current procedures and their costs. As noted above, this kind of change is considered a non-formula adjustment. Here, the NCCI must make use of external data sources due to the shortcoming of their 1960 data base. The NCCI obtains data from companies that perform medical bill reviews.

Medical cost containment is frequently cited as a problem for workers compensation. The percentage of total costs contributed by medical expenses has increased from 30% of total costs to 40% of total costs over the past decade. There is likely to be increased attention focused on medical costs, and therefore, it is necessary that the NCCI improve its ongoing data collection capabilities for medical costs and frequencies in order to both price and monitor the issues of medical costs.

5. Escalation

Some states have provisions that allow for escalation of benefits. The escalation process varies from state to state. For example, escalation may apply to all benefits that exceed a certain duration or it may apply only to specific types of injury (typically fatalities or permanent totals). The escalation may start one year after the injury date or it may begin after a longer delay. Finally, the amount of escalation may depend on the actual change in the CPI or some other index, or the amount of escalation may be capped.

a. Description of Methodology

The sample benefit revisions we reviewed in the previous sections did not have escalation provisions in their statutes. In states with unlimited escalation, NCCI will typically use a 6% escalation in their calculations. In states where escalation is capped, NCCI will either use the cap value or estimate the effect of the cap.

LAW AMENDMENTS

b. Analysis and Comments

In a formula change where the escalation rate is not changing, the treatment of escalation is not significant since the same annuity factor (or equivalently, duration of benefits) will be used for old law and new law. However, if the escalation provisions are changing in a formula benefit calculation, the issue of how to reflect escalation becomes more important, since different annuity factors will apply under the old law and the new law. We find that NCCI's treatment of escalation appears to be reasonable for formula benefit changes. In cases where escalation rates are being modified, we recommend that NCCI filings include more substantiation of its annuity calculations.

Furthermore, if escalation were being modified for permanent partial claims, then we would have a higher level of concern regarding the accuracy of the calculations. In the example discussed in Appendix E, Part B, regarding the annuity calculations for non-scheduled major permanent partial, we observed a lack of detailed support for the derivation of the annuity factors included with the standard filing material. In addition, based on the NCCI model, the wage loss attributable to the non-scheduled portion of major permanent partial formed more than 60% of the total major permanent partial benefit package. Therefore, in such a case it would be important to obtain accurate annuity figures to measure the impact of a change in escalation.

6. Relationship of Benefit Changes to Trend

The goal of the NCCI benefit evaluation model is to estimate the change in loss dollars associated with a change in benefit parameters. However, NCCI uses this information as input to the ratemaking process which aims to compare an estimated future level of losses to an estimated future exposure base.

As discussed, in the trend chapter of the Examination, Section II.B.3, benefit changes can be expressed in either of two ways: (1) as a percentage change in absolute loss amounts, as is done in the NCCI model, or (2) as a change in loss amounts relative to payroll. In the second method, a change in maximum and minimum benefits based on a change in statewide average wages generally produces no effect.

LAW AMENDMENTS

If applied consistently, the two methods should produce similar results in many ratemaking situations. Assuming benefit increases over time, Method 1 starts with higher adjusted past loss ratios, but will require less trend; Method 2 will apply higher trends to lower past loss ratios. The difference between the two methods tends to become more discernable as older years of data are used for trending, as Method 2 avoids the distortion in current NCCI adjustment procedures which is noted in Section IX of the trend section of this examination.

A simple example of this principle appears in Appendix F. In states where there are only indemnity benefit changes that match wage inflation (i.e., the percentage relationship between the maximum benefit, the minimum benefit and the statewide average weekly wage remains constant), this principle can be applied by making no adjustments at all to past losses.

In states where benefits change irregularly, a simple way to perform these calculations is to first determine "benefit relativities"; that is, the cost of past benefit levels and the prospective benefit level divided by the cost of an unlimited benefit level (a benefit level without any minimums or maximums). Each of these calculations would be performed using the average wage levels in effect during each of the past experience periods and then for the average wage level projected to be in effect prospectively. Using such a methodology, the adjustment to past loss ratios is determined by dividing the prospective "benefit relativity" by the various "benefit relativities" that existed in the past. (This calculation is simpler when benefit changes are not dramatic at any one time. When a dramatic benefit change occurs, then the expected change in utilization needs to be recognized. This consideration is not, however, unique or different with Method 2 as opposed to Method 1.)

It should be noted that, unlike Method 1, Method 2 requires past loss ratios to be adjusted to a prospective benefit relativity even if there has been no recent law change. In states without automatic benefit adjustments, it might mean that this adjustment would decrease, rather than increase, past indemnity loss ratios at current rate level. This corresponds to the fact that benefit levels decrease relative to exposures when benefits are not changed as the average wage increases. The trend section of this examination explores aspects of the current NCCI methodology (Method 1) in greater detail.

LAW AMENDMENTS

In Section II.B.3 (Trend), recommendations were made regarding the methodology for calculating the impact of benefit changes. It is essential that the same approach be used in trend calculations and in overall ratemaking calculations. We recommend that for states where NCCI implements the alternate approach (Method 2) for trend, then the same change should be made in the benefit evaluation methodology.

LAW AMENDMENTS

LAW AMENDMENTS

IV. REVIEW OF NON-FORMULA BENEFIT CHANGES

The identification of a benefit change as a "formula" benefit change or a "non-formula" benefit change is not clear cut. We asked the NCCI to supply us with all "non-formula" benefit change filings over the past five years. They supplied us with the following five benefit evaluations:

Florida, Effective 7/1/90

Oregon, Effective 7/1/90

New Mexico, Effective 1/1/91

Washington DC Effective 3/1/91

Texas Effective 1/1/91

According to NCCI, a formula change is any change that can be priced by the existing databases, and a non-formula change is a change that requires additional data and information. We consider a formula change will be any benefit revision that involves only one or more of the following items:

- Changes in maximum weekly benefit,
- Changes in benefit level as a percentage of gross wage,
- Changes in waiting periods,
- Changes in retroactive periods,
- Changes in escalation rates,
- Changes in medical fee schedules.

The difference in definitions is significant, because it highlights the issue of when NCCI should use non-formula methodologies.

LAW AMENDMENTS

Our objective for the review of NCCI's non-formula techniques was to review the effectiveness of NCCI when presented with non-formula type law changes. To accomplish this objective, we did the following:

- Listed the kinds of non-formula changes proposed in the states shown above.
- Identified types of non-formula changes that can be expected to occur in the future.
- Listed the alternative techniques and data sources NCCI used in the states shown above.
- Outlined an alternative approach to pricing non-formula benefit changes.
- Discussed public perception of NCCI's role in benefit pricing.

Our results are described below.

A. Typical Non-Formula Changes

Based on our review of the benefit pricing filing material submitted to us by the NCCI (for the states noted above), we observed the following non-formula issues:

1. Wage loss percentages - FL, TX
2. Wage loss depends on permanent impairment rating - FL
3. Compensability of pre-existing condition - OR
4. Occupational disease standards - OR
5. Use of managed care - OR

LAW AMENDMENTS

6. Standards for disability ratings - OR, TX
7. Eliminate "Economic Permanent Totals" - NM
8. Guidelines for rating permanent partial - NM
9. Vocational rehabilitation changes - NM, DC
10. Changes to benefit administration - TX

B. Future Non-Formula Changes

Based on these 10 items, and our additional research, we have developed a classification of 8 categories where we expect non-formula changes to occur in the upcoming years. These categories are:

1. Compensability,
2. Objective standards for the evaluation of permanent partial injuries,
3. Changes in compensation for permanent partial,
4. Changes in rehabilitation programs,
5. Changes in benefit administration,
6. Changes to reduce litigation,
7. Attempts to decrease interdependence of economic conditions (e.g, unemployment) and workers compensation benefits,
8. Medical cost containment issues.

LAW AMENDMENTS

Each of these areas is discussed below.

1. Compensability

This category includes all attempts to restrict or more clearly define what injuries will be covered by workers compensation. Examples include changes in coverage for heart attacks, stress claims, and occupational disease. Coverage of pre-existing conditions or second injury issues would also fall into this category.

2. Objective standards for the evaluation of permanent partial injuries

This item would include the use of guidelines for disability ratings, such as the AMA guide, as well as modifications based on age, education, and other factors. In some states, if all injuries are required to be evaluated by guidelines, then the difference between scheduled and non-scheduled injuries is reduced. However, to estimate the impact of cost changes under such a system, NCCI would require more detailed information on non-scheduled injuries.

3. Changes in compensation for permanent partial injuries

This item would include conversion to a wage loss system, removal of a wage loss system, and changes in wage loss systems. It could also include changes in the definitions of wage earning capacity and of disability. Some of the issues here overlap with the standards for the evaluation of permanent partial injuries cited above.

4. Changes in rehabilitation programs

States are constantly changing their approaches towards vocational rehabilitation. Some states are making the programs mandatory, while others are converting mandatory programs to optional programs.

5. Changes in benefit administration

A prime recent example is Texas, which revised the entire approach to handling and adjudicating claims. Other states have considered changes in the use of independent medical examiners and in staffing levels at Workers Compensation Commissions.

LAW AMENDMENTS

An important component of benefit administration is the area of dispute resolution. We expect that a number of states will be enacting legislation that will impact this area. Examples of possible changes include encouraging/or requiring informal hearings, adding or subtracting layers to the chain of the dispute resolution mechanism, encouraging/discouraging the use of lump sum settlements, as well as many other potential changes.

The issue of changes in the permissibility of lump sum settlements is an important consideration, but is not reflected in NCCI pricing models.

6. Changes to reduce litigation

While this area relates closely to changes in benefit administration (e.g. regulations regarding informal conferences), states may also change how lawyers are reimbursed for representing claimants.

7. Attempts to decrease interdependence of economic conditions and workers compensation benefits

This would include changes in "deemed wages", changes in job search requirements, and other factors. (Deemed wages are the wages an injured employee is considered to have earned based on an offer of employment.)

For example, the New Mexico law change enacted January 1, 1991, changed the definition of permanent total to include only "presumptive" permanent total cases, that is, total loss of use of two major members. The previous definition allowed permanent total to be awarded if the injured worker was unable to work in a suitable occupation.

In Maine, the November, 1987 law change restricted permanent total to presumptive cases and those cases failing a statewide work search requirement. The statute says

"Any employee who has reached maximum medical improvement and is able to perform full-time remunerative work in the ordinary competitive labor

LAW AMENDMENTS

market in the State, regardless of the where the availability of such work in and around his community, is not eligible for compensation under this section."

We expect to see other attempts to unlink the condition of the economy from the amount of workers compensation benefits.

8. Medical cost containment

This would include changes in physician selection rights, changes in managed care requirements, changes in the use of chiropractors, adoption of utilization guidelines and other factors.

C. NCCI Approach to Non-Formula Changes

This issue is affected by recent staffing changes at NCCI. In the past, the benefit pricing unit at NCCI consisted of approximately 6 people reporting through the Vice President of National Affairs, to a Senior Vice President, to the Chief Operating Officer. In the current structure, the Benefits Pricing Unit reports to the Senior Vice President, one step closer to the President, and more important, staffing will increase to approximately 22 people.

These substantial changes may make our comments or analysis based on the past structure irrelevant for future activities. However, we will describe some of the issues relating to NCCI's past performance as these may provide some guidance as to how NCCI might best focus its efforts.

1. What is a non-formula rate change?

We previously described the difference between our definition of formula changes and NCCI's definition. In the chapter on formula pricing, we noted that NCCI tools worked effectively in situations fitting our strict definition of formula changes. This is due to the relative insensitivity of wage tables and other distributions to the normal formula law changes. If the distributions might shift from old law versus new law, or if the type of change is broader than the typical change, we would consider it to be a

LAW AMENDMENTS

non-formula change. We believe it is important that NCCI recognize when its tools will be appropriate and when they will not be appropriate.

2. What alternative techniques or data sources did the NCCI use in their analyses?

Even when NCCI recognizes a proposed benefit change as non-formula, they still structure their pricing efforts around the formula pricing components. That is, pricing by type of injury and using, to the extent possible, the tables and relationships of the formula pricing. However, they add external data inputs.

In our review of the 5 non-formula rate filings, we observed the use of a number of alternative data sources including:

- Surveys of claims personnel,
- Insurance department studies,
- Experience in other states,
- Samples of claims at the Workers Compensation Commission,
- Local Workers Compensation Commission reports,
- Detailed Claim Information data,
- Government statistical reports,
- Studies/Surveys with local insurance claims personnel and local state agencies.

Regarding alternative techniques, we noted the use of the following:

- Evaluation of Claim files under alternative legislation,

LAW AMENDMENTS

- Use of estimates derived by other parties (e.g. in Florida, NCCI used some of the findings of another consulting firm in estimating the impact of some of the law change provisions on medical costs),
- Greater reliance on assumptions of distributions. For example, for a Texas law evaluation, assumptions had to be made regarding the distribution of losses subject to attorneys fees.

Clearly, the extra data and techniques noted above can be a valuable addition to the pricing approach. We find that all of the items listed above have the potential to add additional insight to the pricing process. However, a review of the actual application of the data and techniques noted above is beyond the scope of our assignment.

A key issue is knowing when the formula approach does not apply. NCCI has been inconsistent in this extremely important area.

D. Framework for Pricing Non-Formula Benefit Changes

The pricing of non-formula changes in benefit levels is a complex problem. It is complex for reasons that include the following:

- Reliable estimates cannot be derived from purely "mechanical" models.
- The pricing depends on judgement regarding the choice of data to be used and the assumptions to be applied in producing a pricing model.
- The pricing models are subject to the use of alternative assumptions that would, in turn, lead to different results.

If the situation involved merely tabulating frequencies and costs under the current system and then calculating revised costs only under the revised system, the problem would be approachable on a purely mechanical level. This is the approach NCCI follows in their formula benefit pricing. Given a sufficiently detailed and up-to-date data base, any benefit change that only affected the relative price of components

LAW AMENDMENTS

could be evaluated. However, it is possible that the required size and detail of the data base could make the pricing problem monumental.

Unfortunately, workers' compensation is a more complex system than that. The overall cost of the system is affected by costs and frequencies of claims. However, frequencies are influenced by behaviors, and behaviors will change based on various incentives. As legislation is changed, incentives will change.

The cost of a workers compensation system is affected by many external factors. For example, we have compiled the following list which itemizes a number of factors that could reasonably be expected to impact on the number of workers compensation claims filed in a given state.

1. Benefit Level

A number of studies have researched the question of the relationship between the frequency of claims and the benefit level/wage replacement rate. A number of these studies have concluded that increases in benefit levels are highly correlated with increases in claim frequency. (NCCI procedures rarely reflect this relationship.)

2. Unemployment Rate

As unemployment levels change, the rate of workers compensation claim filings may also change. In addition, the rating mechanism charges employers based on current payrolls. This may result in a mismatch for insurers between exposure to loss and premium income.

3. Work Force Age

A more experienced work force may tend to have a different level of claims activity than a less experienced work force. Furthermore, older workers may be subject to more injuries, or their injuries may be more serious. Injured workers near retirement may have a reduced incentive to return to work.

LAW AMENDMENTS

4. Income Level

A highly paid work force may tend to file fewer claims since their wage replacement rate may be very low. On the other hand, once a claim is filed, the level of attorney involvement may differ by wage level and the settlement value of the claim may differ. These factors may cause a different distribution of small and large claims based on income level.

5. Safety

A safer work place would tend to give rise to fewer claims.

6. Medical Insurance Availability

If no other medical insurance is available, this may tend to encourage the use of the workers compensation system.

7. Attorney Involvement

The size and interest of the attorney population may affect the level of claim filings. In addition, the workers compensation law and its provisions for compensating attorneys is a related issue.

8. Administrative Process

If the Workers Compensation Commission is perceived as permissive, this may tend to encourage claim filings. Additionally, if the administrative process is backlogged, this may have complex impacts on the frequency and size of workers compensation claims.

9. Unionization

Unions may tend to keep the work force more informed of their rights and remedies.

LAW AMENDMENTS

10. Self-Insurance

If the "better" risks in a market self-insure, the remainder will tend to have a higher claim frequency.

Clearly, a pricing model, that reflected all of the above factors and their inter-relationship would be complex. Even though all variables cannot be fully considered, the most important changes NCCI could make to improve their ability to more accurately price non-formula benefit changes are the following:

1. Improve the method of identifying law changes significant enough to require the use of non-formula techniques. NCCI might use sensitivity tests to judge when results are highly dependent on old or untested assumptions. For each of the key elements in a benefit pricing analysis, NCCI could estimate the cost impacts using a range of benefit values for those assumptions. Then they could demonstrate how the outcomes would vary based on changes in the input assumptions.

Another mechanical trigger might be a comparison between the actual average claim size based on WCSP data compared to the average claim size derived from the NCCI pricing mechanism. (This topic is discussed in Appendix E.) Large differences could indicate that the pricing mechanism does not properly reflect the operation of the workers compensation system in the state being studied.

Other possible means to improve the recognition of law changes significant enough to require non-formula techniques would involve greater use of local advisors.

2. Increase the utilization of state specific information regarding the workers compensation benefit system in the jurisdiction being analyzed. A potential criticism of the NCCI has been that all the tables and formulas underlying their benefit pricing are based on countrywide data. This can be a more acute problem when the state enacting revised legislation is in a "crisis" mode. Local representatives at that point may feel that their state is far from average. To address this problem, NCCI is planning on expanding their DCI call to all states.

This is a valuable step in the right direction. Moreover, current efforts by the NAIC and the International Association of Industrial Accident Boards and Commissions

LAW AMENDMENTS

(IAIABC) are resulting in recommendations for the capture of additional data. We feel that it is crucial that more data be available, and if data requirements can be common among the states, this will improve the quality of research. We have not explored what the appropriate level of data elements should be for evaluating workers compensation systems. A review of the extent of additional data collection is beyond the scope of our assignment.

3. Rely on input from non-actuarial areas (e.g., economics, claims, legal, etc.) in developing pricing models. The workers compensation benefit system is impacted by many forces and has many different players participating in the process. At a minimum, input from local claims personnel and local attorneys should be evaluated. Other sources of insight could include local Workers Compensation Commission members and Insurance Department personnel.

4. Develop a data collection model facilitating retroactive review of the effects of major benefit changes. This would include establishment of measures to test the actual versus expected impact of critical elements in the law revision. For example, if a benefit change was expected to impact utilization, then data measuring the frequency and duration of injuries by type both before the legislative change and after the legislative change could be used to evaluate the effect of the legislation. NCCI has already proposed a number of such procedures to their member companies. Exhibit 18 displays the minutes of a Rates Committee meeting on this topic.

5. Improve models to measure the effect of changes in benefit administration. The Texas benefit changes effective 1/1/91 overhauled the benefit administration and the dispute resolution. However, many states enact smaller adjustments that attempt to increase the efficiency of the benefit delivery process or modify time frames for adjudication. The current NCCI approach attempts to model the way the workers compensation law looks on paper, but typically does not reflect the practical aspects of administration.

6. Develop models to better analyze potential changes in benefit utilization. It would be desirable to have tools available to estimate the changes in the frequency and duration of benefits for both temporary total and permanent partial claims based on changes in other system cost elements. The duration of claims can also be affected

LAW AMENDMENTS

by staffing levels at the Workers Compensation Commission, the extent of legal involvement, and other system elements.

7. Improve the explanatory material included with the benefit pricing report. Currently, for formula benefit changes NCCI provides a large amount of details, but essentially no explanation of what they are doing. For formula benefit changes NCCI should reduce the material included in a filing, but it should develop a clear supplemental report that describes the procedures and explains the methodologies. For non-formula benefit changes, NCCI should increase the amount of explanatory material and indicate clearly, assumptions used and the data sources.

E. Public Perception of NCCI's Benefit Pricing Methodology

We interviewed a number of parties involved with various aspects of workers compensation and asked for comments regarding their perception of how the NCCI prices benefit changes. (This involved telephone interviews with 8 persons from labor, management, research, workers compensation agencies, and other areas.)

While we do not regard our limited sample as complete or a thorough random sample, we believe that the comments are interesting and lend some valuable insight into our research.

Generally, those interviewed believe NCCI benefit pricings are difficult to understand. Most interviewees also stated that they found the NCCI personnel to be cooperative and reasonable. However, the lack of intuitive understanding of the material by the recipients reduces the confidence in the conclusions.

We agree with these observations. We find that the benefit formulas and pricing are difficult to understand, even for parties with substantial expertise in the area. Moreover, in non-formula valuations, the problems are more pronounced.

LAW AMENDMENTS

LAW AMENDMENTS

V. TESTS OF THE WAGE DISTRIBUTION TABLE

A. Updating the 1973 Standard Wage Distribution Table

1. Background

In general, NCCI uses the 1973 Standard Wage Distribution table in all of its benefit calculations. For a recent filing in Texas, they were asked to support whether the use of this table was appropriate. In response to this request, they produced a graph showing the difference between the 1973 wage table and an average table constructed from states with available DCI data. This graph, (Exhibit 19), seems to indicate very little difference between the 1973 table and the average DCI table. In addition, we measured how the individual state tables differed from the 1973 Standard Table.

2. Analysis and Comments

We tested the average change in weekly benefits for a sample revision in temporary total disability costs based on a change in the maximum benefit.

The pricing parameters used were as follows:

	Pre <u>Law</u>	Post <u>Law</u>
% Rate of Compensation	66.67%	66.67%
Minimum Weekly Compensable Wage	\$ 0.00	\$ 0.00
Maximum Weekly Compensable Wage	\$380.77	\$415.38
Average Weekly Wage	\$353.07	\$353.07

We priced this component of a benefit change with the 1973 Standard table and several individual DCI State tables. (See Exhibit 20 for details underlying our calculations.) We generated the following outcomes:

LAW AMENDMENTS

<u>Wage Table Used</u>	(1) <u>Benefit Change</u>	(2) =[(1)/1973 Std]-1.0 <u>Ratio to Base</u>
1973 Standard	3.5%	Base
Wisconsin	4.1%	+0.6%
New York	4.3%	0.8%
Florida	3.6%	0.1%
USL&H	2.3%	-1.2%

Column (2) shows the effect on the benefit calculation from changing from the 1973 Standard Wage Table to various state tables.

These results show that for the sample benefit calculation, the effect of table changes is under 1%, except for USL&H.

Even though the differences in benefit pricing from using various wage tables are slight, it seems prudent to revise the distributions underlying benefit pricing more frequently than once every twenty years. However, it is reassuring that the key ingredient to the formula benefit pricing appears to produce stable results. We recommend that once the revised DCI data is available, NCCI study the possibility of using state DCI generated wage tables in all states.

We believe the use of state wage tables may be feasible. Arthur Anderson & Company (AA&Co.) did some preliminary analysis of data reported through the DCI that is used to generate the state by state wage tables. Although they did not study the source data at a company level, they reviewed the conversion process from company reports to DCI files. Based on their preliminary findings, the wage data in the DCI appeared to be of reasonable quality. The DCI captures wage data for a sample of injured workers. Wage tables are constructed based on a wage distribution of injured workers only, as opposed to all workers.

LAW AMENDMENTS

B. Wage Distribution Tables for Class Groups

1. Background

To study the effect of varying the wage tables by class group, we requested that NCCI use DCI data to construct wage tables by Industry Group (i.e., Manufacturing, Contracting, and All Other) for the four largest DCI states, Florida, Illinois, Michigan, and Pennsylvania. Using this additional information, we conducted a series of tests as follows:

- Test 1. For each industry group for each state, we observed the percentage of total workers and the percentage of total wages at various relativities to the statewide average wage (Exhibit 21).
- Test 2. For the state that had the largest spread between the average weekly wage among the Class Groups (Illinois), we tested the sensitivity of the standard NCCI pricing formula using the standard NCCI pricing formula and a revised pricing formula that measures the effects separately by industry group under two scenarios:
- a. Change the maximum weekly benefit from 100% of the statewide average weekly wage to 150%. This test was selected as a potentially large benefit change that would not be expected to occur very often.
 - b. The maximum weekly benefit increases 10%. This test was selected as representing a common type of benefit adjustment.

The results of the two tests appear in Exhibits 22 and 23.

2. Analysis and Comments

As described in Section III, the Wage Distribution Table is used to estimate the average weekly benefit for injured workers under the workers compensation benefit structure. The table displays the percentage of total workers (known as the "A ratio" or "A value") and the percentage of total wages (known as the "B ratio" or "B value") at various relativities to the statewide average wage.

LAW AMENDMENTS

Test 1. The graphs seem to indicate that the "A" and "B" ratios do not vary much from state to state for each classification group. A closer examination of the actual values shows that this is generally the case. For example, in the manufacturing group, at $R = 1.0$, the "A" values for the four states are as follows:

<u>State</u>	<u>"A" Value</u>
Florida	60.9%
Illinois	55.6%
Michigan	55.1%
Pennsylvania	61.5%

This indicates that in Florida, for example, 60.9% of the workers earn less than the statewide average wage. The amount of data available in some of the individual class group categories by state is sometimes small. For example, the contracting group Table for Pennsylvania was constructed based on only 46 claims. Therefore some of the results observed may tend to be unreliable. In any case, the more practical considerations of how benefit pricing may vary by use of alternative tables is discussed below.

Test 2a. Based on this test, we observed that the alternative methodology produced a higher indicated change for the benefit adjustment (+3.0% versus +2.5%). This is a relatively small difference, and as noted, it is based on a rather substantial benefit change, which should not occur with great frequency. However, the relative changes by industry group are substantially different ranging from a low of +0.9% (manufacturing) to a high of +8.0% (contracting) (Exhibit 22).

Test 2b. This test produced a smaller spread between the totals by industry group as compared to the standard NCCI method (+1.4% versus +1.0%). Again, the alternative model produced a higher result. However, it is interesting to note that the spread between manufacturing and contracting is still significant (+0.5% for manufacturing +4.1% for contracting) (Exhibit 23).

LAW AMENDMENTS

In terms of the overall rate level calculations, reflecting class differences in the wage tables may produce slightly different results than the current procedure. We are not sure of the ultimate effect, since our test tables were based on small data samples from only a single state. This factor by itself is of concern, but it is not persuasive enough to require future action.

The effects by industry group do appear to have the potential to vary widely. This may have implications for classification ratemaking. For example, in determining the classification group differential, a wage trend index is applied. Investigating whether this index overlaps with differences in benefit pricing by classification group is an area for future research.

However, it is important to be aware that our results are based on one state that had a high spread between the average wages by classification group. Different results may be obtained if a broader investigation is undertaken. We recommend that NCCI consider future research into this area.

SAMPLE CALCULATION OF AVERAGE WEEKLY BENEFITS
BASED ON 1973 STANDARD WAGE DISTRIBUTION TABLE

(1) % RATE OF COMPENSATION	50.0%
(2) MINIMUM WEEKLY BENEFIT	\$25.00
(3) MAXIMUM WEEKLY BENEFIT	\$150.00
(4) STATE AVERAGE WEEKLY WAGE (SAWW)	\$200.00
(5) MAXIMUM WAGE BASED ON (2) (2)/(1)	\$50.00
(6) MINIMUM WAGE BASED ON (3) (3)/(1)	\$300.00

(7)	(8)	(9)	(10)	(11)	(12)
WAGE INTERVAL MIN MAX	WAGE TABLE "R" FACTOR NEAREST .05	WAGE TABLE "A" FACTOR (%)	WAGE TABLE "B" FACTOR (%)	AVG WEEKLY WAGE (4)*(10)/(9)	AVG WEEKLY BENEFIT SUBJ TO MAX & MIN (1)*(11)
\$0 - \$ 50.00	0.00 - 0.25	2.1432	0.3483	32.50	\$25.00
\$ 50.00 - \$300.00	0.25 - 1.50	85.7894	76.3064	177.89	\$88.95
\$300.00 -	1.50 -	12.0674	23.3453	386.92	\$150.00

(13) STATE AVERAGE WEEKLY WAGE	\$200.00
(14) STATE AVERAGE WEEKLY BENEFIT	\$94.95

NOTES:

- Column (7) is based on columns (5) and (6).
- Column (8), the "R" factor, is the ratio of the wages in column (7) to the SAWW in column (4).
- Columns (9) and (10) are from the 1973 Standard Wage Distribution Table.
The "A" factor from the Wage Distribution Table is the percentage of workers earning not more than "R" times the average wage.
The "B" factor from the Wage Distribution Table is the percentage of wages earned by the percent of workers in "A".
- Column (12) must be at least the minimum weekly compensation from (2) and at most the maximum weekly compensation from (3).
- Column (13) is the sum of the product of columns (9) and (11).
- Column (14) is the sum of the product of columns (9) and (12).

PROCEDURE

BLOOD

8602	Agglutination for febrile diseases, first antigen	8671	Eosinophile count.....
8603	each additional antigen	8619	Factors 5 and 7.....
8604	Alcohol, blood	8748	Fibrinogen
8683	Ammonium sulfate turbidity	8675	Flocculation tests (Kline, Kahn, etc.) each
8747	Ammonia, blood	8621	Galactose tolerance
8605	Amylase, blood	8681	Hematocrit
8306	Antistreptolysin titer	8677	Hemoglobin, carbon monoxide (qualitative)
8608	Ascorbic acid	8678	methemoglobin (qualitative)
8750	Barbiturate, qualitative	8679	suphemoglobin (qualitative)
8751	quantitative	8684	Heterophile antibody with absorption
8399	Basophilic aggregates (L-E cells) smear preparations	8685	without absorption
8607	L-E chemical test	8625	Hydroxycorticosteroids
8610	bilirubin, total	8690	Icterus index
8611	Bilirubin (Van den Berg) indirect	8625	Inulin clearance
	direct and delayed	8673	Iron, serum
8614	Bleeding time	8674	Iron binding capacity
8617	Blood culture, aerobic and anaerobic, screening	8627	Irregular antibodies, screening
8618	definitive	8635	antibody identification
8620	Blood, red cell count	8744	Lactic dehydrogenase
8622	hemoglobin determination	8670	Latex fixation
8621	white cell count	8691	Lead
8626	differential count	8629	Leucine aminopeptidase
8628	complete count (CBC)	8692	Lipase
8631	Bone marrow, collection and evaluation of material	8693	Lipids, total
8636	evaluation of material only	8694	phospholipids
8637	Bromides	8630	Macroglobulins, screening
8638	Bromsulphalein	8639	cryoglobulins, screening
8640	C-reactive protein	8631	Magnesium
8641	Calcium	8695	Non-protein nitrogen
8646	Cephalin flocculation	8699	Oxycorticoids
8650	Chlorides	8698	Oxygen, blood
8652	Cholesterol	8696	Oxygen content (arterial blood)
8653	Cholesterol esters	8669	Paternity testing, per individual
8613	Cholinesterase	8703	pH blood
8989	Circulation time	8700	Phosphatase, acid
8656	Clot retraction	8633	prostatic fraction
8643	CO ₂ combining power	8701	alkaline
8647	arterial puncture	8702	Phosphorus
8648	CO ₂ content (arterial)	8630	Platelet agglutination
8658	Coagulation time (Lee & White)	8704	Platelet count
8659	other methods	8642	Platelet pack, preparation
8615	Cold agglutinins	8706	Potassium
8661	Complement fixation tests (Wassermann, etc.)	8797	Protein bound iodine
8662	Complement fixation, quantitative	8704	Prothrombin time
8644	Congo red	8710	Prothrombin utilization
8739	Coombs test, direct	8711	Red cell fragility
8753	indirect	8713	Reticulocyte count
8666	Creatine	8672	Rh genotype
8681	Creatinin	8716	Rh titer
8689	Creatinine clearance	8752	Salicylates
8740	Crossmatch, blood, with saline, albumin and Coombs techniques	8720	Sedimentation rate
8667	Electrophoresis pattern, protein	8709	Sickle cell preparation
8668	lipoprotein	8722	Smears for parasites (malaria, etc.)
8616	hemoglobin	8645	Smear, peripheral blood evaluation
		8726	Sugar
		8728	Sugar tolerance, 3 hours
		8729	5 hours
		8649	Sulfonamide level
		8746	Thiocyanate
		8631	Thorn test

CALCULATION OF EFFECT OF LAW AMENDMENT ON FATAL BENEFIT COSTS
BASED ON NCCI DISTRIBUTIONS AND REMARRIAGE TABLE

	10/1/88 -----	7/1/89 -----
1. COST OF DEPENDENCY	\$86,763,623	\$89,846,238
2. BURIAL COST (1,000 cases * \$1,000 per case)	\$1,000,000	\$1,000,000
3. SPECIAL FUND ASSESSMENT (147 non-dependency cases * \$1,150)	\$169,050	\$169,050
4. COST OF REMARRIAGE AWARD	\$1,561,506	\$1,617,037
5. TOTAL COST OF FATAL BENEFITS (1) + (2) + (3) + (4)	\$89,494,179	\$92,632,325
6. EFFECT		1.035

NOTES:

1. The data is based on a recent Arizona filing and assumes the NCCI distribution of dependent survivors and a remarriage decrement in the computation of the annuities.
2. The remarriage awards are based on a two year lump sum benefit, the NCCI frequency distributions and the NCCI calculation of the remarriage values.

COLORADO LAW MEMO

Changes Resulting from the Medical Fee
Schedule Change

EFFECTIVE: August 1, 1988

Increase in the Conversion Factors Applied to Medical Fee Schedule

TOTAL EFFECT: +2.9%

COLORADO LAW MEMO

MEMORANDUM

Re: **Evaluation of the Effect on Colorado
Compensation Costs Resulting from Medical
Fee Schedule Change, Effective 8/1/88**

This memorandum presents the principles underlying the calculation of the effect on compensation costs resulting from the adoption of the Colorado Department of Labor and Employment Workers Compensation. The Fee Schedule Change is effective August 1, 1988. According to standard principles and procedures, the effect was determined by comparing the monetary cost prior to the change with the monetary cost under the new schedule.

Communication with the Fee Schedule Coordinator informed us that whereas adoption of more current CPT coding necessitated considerable change to the Fee Schedule - especially introduction of new and deletion of old codes - relative values were generally left unchanged and new conversion factors were adopted together with some administrative rule changes. Accordingly, our pricing concentrates on the impact of adopting the revised conversion factors. For each medical cost category, fee items were matched with the Medical Cost Distribution of the National Council. The matched fee procedure's prior and revised conversion factors were then weighted by the relative frequencies from the Medical Cost Distribution. Because the 1988 schedule stipulates different conversion factors for the reimbursement of hospitals and physicians, both factors were afforded their respective weight in determining the frequency distribution based on the 1988 conversion factors. The comparison results in an increase in the cost of matched procedures, unmatched were assumed to undergo the same proportional increase. The effect of these changes in Medical Fee costs were further weighted by the complete Medical Cost Distribution to determine the overall effect on medical benefit costs to be an 8.7% increase. Finally, the overall effect on benefit costs, calculated to be a 2.9% increase, is determined from a weighted average of the effects on medical and indemnity benefits using the losses incurred during the latest two policy periods as weights.

The following exhibits are attached:

- Exhibit I - Impact by Type of Injury of the Medical Fee Changes on Benefit Costs, Effective August 1, 1988
- Exhibit I-A - Overall Effect of the Medical Fee Changes on Benefit Costs, Effective August 1, 1988
- Exhibit II - Determination of the Effect of the August 1, 1988 Medical Fee Changes on Total Medical Costs
- Exhibit III - Determination of the Effect of the August 1, 1988 Medical Fee Changes on Matched Fee Items

EXHIBIT II

The Effect on Medical Costs of House Bill 2292, Effective 1-1-86

House Bill 2292 sets the maximum allowable charge for procedures covered by the medical fee schedule at the 75th percentile. Currently, law allows doctors to request, on a case-by-case basis, billing as high as the 90th percentile. (Doctors do not need special permission up to the 75th percentile.)

Conversations with claims personnel indicate that 90% of the doctors are currently billing at the 90th percentile, the other 10% at the 75th percentile. In addition, we estimate that 55% of all medical costs are covered by the medical fee schedule. This results in an effect on medical costs of:

$$\frac{((\frac{75}{90})(.90) + (\frac{75}{90})(.10)) \times .55) + .45}{((\frac{90}{90})(.90) + (\frac{75}{90})(.10)) \times .55) + .45} = .917$$

MINUTES
RATES COMMITTEE
MEETING OF APRIL 3, 1990

RC-89-12

Update on Joint Meeting Projects

Background:

At the February 17, 1988 joint Actuarial and Rates Committee meeting, the members prioritized issues of long term prospects for Workers Compensation and set goals for the top ten items.

Discussion:

Staff provided a final report on the one outstanding Joint Meeting Project: Benefits Utilization Growth and Retrospective Review of Law Changes. The Proceedings of the Workers Compensation Congress, which includes a paper on Benefit Utilization, were distributed. The Congress paper on Benefit Utilization summarizes research efforts to measure changes in utilization that accompany increases in workers compensation benefits. The paper of the Proceedings reflects input received at and subsequent to the Workers Compensation Congress.

Attached please find a report on the two recent NCCI research papers on Benefit Utilization and a report on the proposed studies concerning Retrospective Review of Law Changes provided at the meeting. The study proposals will be reviewed by the Claims Committee at its next meeting.

NATIONAL COUNCIL ON COMPENSATION INSURANCE
April 3, 1990

RETROSPECTIVE REVIEW OF LAW CHANGES

SUMMARY:

Significant changes in the various workers' compensation statutes have been enacted in recent years. The legislation has addressed many aspects of the system: indemnity benefits, dispute resolution, attorney fees, medical fee reimbursement schedules, utilization reviews, and safety programs. Many of these features are very difficult to price on a prospective basis. However, a retrospective review of the actual impact of certain major legislation would provide insights that would help to more accurately price similar law changes in the future.

OUTLINE OF PROPOSED STUDY, BY TOPIC:

I. Introduction of a Medical Fee Schedule

Issues: We do not capture data on current and customary charges which are needed for comparison with the schedule. Also, implementation of a medical fee schedule may be followed by increased utilization. We do not have the necessary information to measure this. Our current procedure is to modify the medical trend factor.

Example: Michigan or Texas

Proposal: A special calendar call to capture paid medical losses before and after the effective date of the fee schedule. The call would capture number of procedures [CPT code] and average payment.

Priority: A

II. Change in Basis of Permanent Partial Award

Issues: There are several methods used to determine Permanent Partial awards: schedule combined with non-schedule, wage loss, loss of earning capacity or impairment rating. Some methods are less predictable and involve more litigation than others. As a result, some states have changed the basis for determining their awards. We do not have access to data that would allow us to adequately price the effect of changing from one method to another, or of comparing awards under different systems.

Example: Oregon Prospective: Colorado

Proposal: A special call for data on Permanent Partial losses, including nature and cause of injury, basis for award, disability rating, modification (if applicable), attorney involvement and fees, duration of benefits and total loss. The data would be collected on an accident year basis before and after the law change.

Priority: A

III. Dispute Resolution

Issues: There are several topics under this general heading: appeals under trial de novo, where evidence and decisions at prior administrative hearings are inadmissible; the role played by the Workers' Compensation Board in contested cases; and attorney compensation.

Example: Trial de Novo: Oregon Prospective: Texas
Attorney Fees: New Mexico

Proposal: (1) Trial de novo: A special accident year study comparing percent of all claims that are contested before and after the law change, including information on actual verdicts on appeal. (2) Attorney Fees: Special accident year calls to track average awards with and without attorney involvement, percent of cases with attorney involvement and attorney fees before and after the effective date of the law change.

Priority: A

IV. Wage Loss

Issues: Currently, we do not have sufficient information to compare wage loss and schedule/impairment-based Permanent Partial awards. In addition, post-injury wages and deemed earnings have not been monitored since wage loss was introduced. This information is needed to accurately measure losses under wage loss systems.

Example: Florida, Louisiana

Proposal: A special accident year detail call for wage loss data capturing pre-injury wage, post-injury wage, deemed earnings, as well as information on nature and cause of injury and impairment rating.

Priority: B

V. Benefit Utilization

Issues: Significant changes in statutory benefits are believed to affect behavior. Specifically, large increases in benefits are accompanied by increases in the number of workers' compensation claims filed and the length of time for which benefits are paid. Many states increased benefits provided under workers' compensation in response to the recommendations of the National Commission. Wage replacement rates were increased, along with increases in minimum and maximum weekly benefits and durations for permanent injuries. Retroactive periods were shortened. More recently, reversals are occurring in states that are trying to curb increasing costs. Proposals are being drafted to limit durations to a fixed maximum number of weeks, and increase retroactive periods.

Example: Increase: New Hampshire
Decrease: Maine

Proposal: (1) A special accident year call to measure frequency and severity by benefit type before and after the effective date of the legislation, separately for age groups, general occupational headings, marital status/whether spouse is employed. (2) Continuation of research begun by Economic and Social Research Department in this area.

Priority: B

VI. Change in Average Weekly Wage Calculation

Issues: Several changes in the average weekly wage calculation have been made in various states: use of spendable wage as the base, inclusion of certain fringe benefits and applying different rules to part-time and/or seasonal workers.

Example: District of Columbia

Proposal: A data call containing the following claimant information: gross and net wage, fringe benefit additions, age, occupation, whether seasonal or part-time worker. Additionally, comparisons of average indemnity benefits before and after the law change.

Priority: C

VII. Work Environment

Issues: There are two major topics under this heading -- safety programs and drug/alcohol abuse.

SAFETY PROGRAMS: Recent legislation and legislative proposals have addressed safety consciousness from both employer and employee standpoints. Employers are being required to establish safety programs that meet certain standards. Incentives are generally either pricing credits for employers who meet the standards and/or fines or debits for employers in violation. Employees who violate established standards or fail to use necessary safety equipment lose all or part of their benefits.

DRUG/ALCOHOL ABUSE: Stricter standards and greater testing authority are being added to the statutes. Employees generally lose all or part of their benefits when alcohol/drug impairment contributes to an accident.

Example: Florida

Proposal: Special studies to collect data on percent of claims involving safety violations, or use of drugs/alcohol. Also to be collected is information on penalties assessed (employer as well as employee) and any benefit reductions. This data may only be available in claim files.

Priority: C

Additional Comments: The DCI is being expanded to capture data from all states, and to capture additional information in response to the NAIC reporting proposal. The new DCI will help us monitor many of these types of changes in the future, and will allow us to do more direct pricing and analysis as the file is built up. However, it will be several years before enough data will be collected for this purpose.

This proposal concentrates on retrospective analyses of significant prior legislation. Texas recently passed SB 1, which takes effect on January 1, 1991. A claims study comparing costs before and after SB 1 may be needed to accurately measure the true impact of this legislation.

Notes: Data provided by NCCI.

* Number not provided by NCCI.

R is the ratio of wage to state average wage.

A is the percentage of workers earning less than or equal to R times the state average wage.

B is the percentage of wages received by the percentage of workers in column A.

LAW AMENDMENTS: TECHNICAL APPENDIX A

CRITICAL VALUES

This Appendix will address some issues related to the concept of "critical values". Critical values are claim size amounts that NCCI uses to distinguish major permanent partial claims from minor permanent partial claims.

Until the late 1960's, major and minor permanent partial injuries were distinguished based on the reporting insurance company's qualitative evaluation of the injury. Cases with 25% or less impairment were to be categorized as minor and cases with greater than 25% impairment were to be categorized as major.

Commencing January 1, 1967, a quantitative value for each state was established (the critical value). The critical value was selected by state in order to keep the proportion of major and minor claims similar to the proportions that existed under the qualitative categorization. The advantage of the critical value system was that companies no longer had to categorize claims into major and minor, based on what many insurers felt was subjective criteria. Instead, the categorization could be handled "objectively" by the computer systems at NCCI.

For the next two decades, critical values were adjusted based solely on changes in benefit level pricing. Wage and other inflation measures were not used to adjust the critical values. Thus, over the course of time, claims that were once minor (since they were below the critical value) became major as inflation pushed them past an unescalated critical value.

Exhibit A3 shows the effect in a sample state of the drift in critical values. At time zero, the average permanent partial claim size is \$20,000 (major and minor combined) and the critical value is also \$20,000. 23% of the total permanent partial claims are major while 72% of total permanent partial dollar are from major.

After 10 years of inflation, at 5% per year, if the critical value is unescalated then 35.1% of total permanent partial claims are major and 82.4% of total permanent partial dollars are major.

The exhibit also shows results after 20 years of inflation.

LAW AMENDMENTS: TECHNICAL APPENDIX A

If the critical values were escalated, then the relative proportions of claims and dollars in the major category would remain constant.

Currently, NCCI is attempting to adjust the critical values in all states to realign them to their original purpose. Since the indicated shift in critical value generally exceeds 50% (ranging from -2% in Oregon to +381% in Washington DC, as displayed in Exhibit A1), the change is being implemented with a transition program. During that transition time, care must be taken in interpreting any data based on splitting permanent partial claims into major and minor categories. NCCI memos describing the critical value issue and their proposed solution are attached as Exhibit A2.

For most practical purposes, the transition will create no difficulties. There would be a significant impact only if the pricing produced substantially different effects for major and minor permanent partial claims. Based on benefit changes in all states from 1985-1989, we only observed 4 cases out of 288 benefit changes where the difference between the benefit change for permanent partial major differed from the change for permanent partial minor by more than 4.6%. These are displayed below:

<u>State</u>	<u>Year</u>	<u>Change for Major</u>	<u>Change for Minor</u>	<u>Difference</u>
Maine	1987	-57.4	-18.1	39.3
Montana	1987	-28.0	-53.2	25.2
Maryland	1988	+0.5	-23.8	24.3
Mass.	1986	-18.7	- 2.0	16.7

Future law changes aimed at cost containment may have different impacts on seriously injured workers as compared to less seriously injured workers. In that case, accurate distinctions between permanent partial major and permanent partial minor claims would be useful, and caution is required in using the separate major permanent partial and minor permanent partial distributions during the transition.

NOTES:

1. Data is based on NCCI memo dated Jan. 31, 1989 regarding "Updated Critical Value Procedures".
2. Column (2) is the selected critical value for 1988.
3. Column (3) is the Indicated Critical Value based on the 1966 major/minor split for benefit changes and cost changes.
4. Column (4) is column (3) divided by column (2) minus 1.0. Required change in critical value.
5. NCCI memos on Critical Values are included in Exhibit 2.

Re: Updated Critical Value Procedures

The current procedure for updating the critical value for a state is to increase the current value by 10% and round to the nearest \$500. As a result of an investigation by Eric Chen and Gina Paglialonga, our critical value update procedure has been revised. The new calculation is briefly described below. Refer to the attached Critical Value Report for greater detail.

Prior to 1966, losses were reported by specific type of injury and a major/minor split was based on the type of injury. In 1966, the procedure was changed to base the major/minor split on the indemnity amount of each claim as opposed to the type of injury. The change in procedure was intended to have no effect. Over time, however, the critical value did not keep up with inflation. In the procedure being implemented, the 1966 split is updated for major and minor permanent partial benefit changes occurring since then. Using the Payroll and Loss Detail file, an indemnity amount (the critical value) corresponding to the percentage split is derived.

Implementation of this procedure is as follows. The critical value will continue to be increased by 10% until it reaches the critical value calculated using the updated 1966 distribution. If the current critical value exceeds the critical value using the adjusted 1966 distribution, the critical value will not be changed. An example of the implementation is shown.

<u>Current</u>	<u>Updated by 10%</u>	<u>Using Adj. 1966 Distr.</u>	<u>New Critical Value</u>
17,000	18,500	15,000	17,000
17,000	18,500	17,500	17,500
17,000	18,500	29,000	18,500

The critical values based on the adjusted 1966 distribution were calculated in October 1987 by Eric Chen and Gina Paglialonga. The critical values are attached. This page will be recalculated in August 1989, and annually in August thereafter. Until updated, we will use the values to determine the appropriate critical value.

Re: Critical Value Update

The 1989 update of the critical value table using the adjusted 1966 distribution has been completed. The table is updated by calculating the 1966 percentage split of major and minor permanent partial losses. The split is then adjusted for benefit changes occurring since 1966. The payroll and loss detail file is used to derive an indemnity amount corresponding to the major percentage. This indemnity amount is the new critical value.

The results of the 1989 update are as follows: In 35 of 37 states, the critical value using the 1966 distribution is significantly higher than the current critical value, therefore the increase of the current critical value is limited to 10%. In the remaining 2 states, the critical value using the 1966 distribution is lower than the current critical value. Steps to update these values are outlined below.

Updates of the current critical values will follow the current procedure. The critical value will be increased by 10% and rounded to the nearest \$500 until it reaches the critical value using the 1966 distribution. If the current critical value exceeds the critical value using the adjusted 1966 distribution by more than 20%, the critical value will be decreased by 10% and rounded to the nearest \$500. If the current critical value exceeds the critical value using the adjusted 1966 distribution by less than 20%, and there is a significant benefit decrease at the time, the current critical value may decrease. An example of this procedure is shown.

<u>Current</u>	<u>Updated by 10%</u>	<u>Using Adj. 1966 Distr.</u>	<u>New Critical Value</u>
\$22,000	\$24,000	\$16,000	\$20,000
22,000	24,000	20,000	22,000
22,000	24,000	23,000	23,000
22,000	24,000	26,000	24,000

A table of the critical values calculated for each state using the 1966 adjusted distribution is attached.

Re: Critical Value Update

The 1990 update of the critical value limits has been completed. Since many states are still very far from the limits, only the following states were updated: Arizona, Arkansas, Indiana, Maine, Maryland, Missouri, Oklahoma, Oregon, South Dakota, Tennessee and Utah.

Calculation of the selected critical valued for 1988 and 1989 will follow the current procedure. The critical value will be increased by 10% and rounded to the nearest \$500 until it reaches the critical value limit using the 1966 adjusted distribution. If the selected critical value exceeds the critical value limit by more than 20%, the selected critical value is decreased by 10%. No states fell into this category. If the selected critical value exceeds the critical value limit by less than 20%, the selected critical value will not be changed. Only Oregon fell into this category. An example is shown.

<u>Current</u>	<u>Updated by 10%</u>	<u>Using Adj. 1966 Dist.</u>	<u>New Critical Value</u>
\$22,000	\$24,000	\$16,000	\$20,000
22,000	24,000	20,000	22,000
22,000	24,000	23,000	23,000
22,000	24,000	26,000	24,000

A table of the selected 1988 and 1989 critical values and the critical value limits is attached.

TABLE VII-1

CRITICAL VALUES

The reporting of permanent partial injuries is to be made under the rules of the Unit Statistical Plan through the use of injury Code 9. All permanent partials not reported under the Option A of the Three Year Fixed Rate Policy procedure will be sorted by the National Council's data processing equipment into Major and Minor based on the following state critical values.

If Option A is selected for reporting experience under Three Year Fixed Rate Policies, such losses will be reported as 3 or 4, for major or minor, respectively.

All Claims	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

"R" is the ratio to the average incurred size of loss.

"A" is the percentage of claims not in excess of "R" times the average incurred size of loss.

"B" is the percentage of incurred losses attributed to those claims not in excess of "R" times the average incurred size of loss.

**LAW AMENDMENTS:
TECHNICAL APPENDIX B**

FATAL INJURIES

The purpose of this Appendix is to describe the details of the methodology employed by NCCI in pricing total fatal disability benefits.

Exhibit B1, Sheets 1-2 display NCCI's summary of the benefits provisions and the law amendment change including a summary of social security offset provisions for fatal disability cases. For this revision, the only change is an increase in the maximum weekly benefit from \$354.69 to \$371.21.

For purposes of this Appendix we will assume that the calculation of the average weekly workers compensation benefits have been computed elsewhere in accordance with the statutory provisions and NCCI's estimate of the state average weekly wage (SAWW). Sample calculations of average weekly benefits using NCCI's formulas appear in Appendix E.

Exhibit B2 is NCCI's exhibit summarizing the calculation of the effect of the law amendment change on fatal disability benefits. Line 1 covers the cost of fatal benefits for the period when the dependents are not eligible for social security benefits and therefore the full workers compensation fatal benefits are received. The NCCI calculation of the old law value is shown in Exhibit B3. The new law calculation is analogous and is not shown in this Appendix.

Line 2 covers the cost of fatal benefits when the dependents receive social security benefits and therefore the workers compensation fatal benefits are reduced. The NCCI calculation of the old law value is shown in Exhibit B4. The new law calculation is analogous and is not shown in this Appendix.

Line 3 is the cost of burial, that is the product of the number of fatal cases (in the sample distribution) and the burial allowance under the statutory provisions, both pre and post-law change.

Line 4 is the cost of special funds. For this state, this is the number of non-dependency fatal cases times the subsequent injury fund assessment dictated by statute.

LAW AMENDMENTS: TECHNICAL APPENDIX B

Line 5 is the cost of remarriage benefits. Out of the sample of 1,000 fatal cases, 356 involve a widow alone (i.e., no children) and 427 involve a widow with one or more children.

The present values of benefits payable to widows in each category is multiplied by the average number in each group. This sum is then multiplied by the two year lump sum award (104 weeks) at the appropriate benefit level (\$236.07 under the old law and \$238.55 under the new law). This calculation is displayed in the footnotes.

Line 6 is the total cost of fatal benefits, that is the sum of lines 1-5. Line 7 is the overall effect of the law change, that is, the total cost in dollars based on the new law divided by the total cost in dollars based on the old law.

Exhibit B3 is an example of the NCCI calculation of fatal disability benefits for dependents not receiving social security benefits. This exhibit is used to calculate the values shown in Line 1 of Exhibit B2. In this exhibit, the cost of fatal benefits is computed over the period of time when the dependents are not eligible for social security benefits. (Note that the cost of fatal benefits for these dependents over the period of time when they receive social security benefits and, thus, reduced workers compensation fatal benefits is included as Exhibit B4.)

Column (1) is the average number of cases out of every 1,000 cases corresponding to the dependency status in column (2). The distribution is based on the Injury Table.

Column (2) consists of the distinct dependency subgroups which are eligible for fatal disability benefits.

Column (3) contains the average number of dependents associated with column (2).

Column (4) is the average age of dependents for each subgroup. (Based on the Workmen's Compensation Injury Table.)

Column (5) contains the type of annuity describing the benefit. The annuity symbol expresses the period of time over which the benefits are applicable. The average age

LAW AMENDMENTS: TECHNICAL APPENDIX B

of the widow is 51 (and the average age of the deceased spouse is age 54). Consequently, they receive the full workers compensation benefit, provided they do not remarry, over the next 9 years. This is reflected in the use of 9 year term life annuity for a person aged 51.

Column (6) contains the present value of an annuity of one dollar per week based on a 3.5% interest rate and the United States, 1979-81 Life Table for Females. Note that the interest rate and mortality table are not displayed in a typical filing.

Column (7) is the average weekly workers compensation fatal benefits for each subgroup based on the pre-law change average weekly wage and the minimum and maximum benefit provisions. The calculation of these values is shown in Exhibit B5.

Column (8) is the total fatal benefit cost in dollars associated with each annuity period computed by multiplying columns (1), (6) and (7).

Exhibit B4 is an example of the NCCI calculation of fatal disability benefits for dependents receiving social security benefits. In this exhibit, the cost of fatal benefits is computed over the period of time when the dependents receive social security benefits and, thus, reduced workers compensation fatal benefits. Column (1) through column (6) have the same definition as the columns in Exhibit B3.

Column (7) is the reduced statutory workers compensation benefit calculated in Exhibit B5, and is based on the size of the workers compensation benefit and the social security benefit. In many cases, the reduced statutory workers compensation benefit is zero, since the social security benefit is greater than the workers compensation benefit. The calculation of these values is shown in Exhibit B4.

Column (8) has the same definition as column (8) in Exhibit B3.

Note that the combined benefits for a specific subgroup in Exhibits B3 and B4 is the total benefit for that subgroup. For example, the total fatal benefits for a widow alone consist of the full workers compensation fatal benefit for a 9 year term life annuity (Exhibit B3) and a reduced fatal benefit for a 9 year deferred life annuity (Exhibit B4).

LAW AMENDMENTS: TECHNICAL APPENDIX B

Exhibit B5 is an example of the NCCI calculation of the reduced workers compensation average weekly benefit for dependents receiving social security benefits as specified in Exhibit B1, Sheet 2 and shown in Exhibit B4. Column (A) is the dependency status. Column (B) contains the primary social security benefit based on NCCI's interpretation of the social security structure. Column (C) represents the initial social security benefit. This is computed as column (B) times the applicable percent from Exhibit B1, Sheet 2 and assumes an annual 5% increase in social security benefits. Column (D) is the previously calculated workers compensation fatal benefit. Column (E) is the reduced workers compensation benefit. The appropriate reduction is based on Exhibit B1, Sheet 1.

Exhibit B6 is an example of the NCCI calculation of the present value of the widows' remarriage benefit. Widows who remarry are eligible for a 2 year lump sum benefit. The present values are computed only for widows alone or widows with no dependent children eligible for the fatal benefits (i.e., over 18 or 19 if a student) provided they do not remarry. The percent of widows who remarry and are eligible for the 2 year lump is the present value for the appropriate column divided by the number of widows sampled. Note that the fractions .0964 and .0733 are carried to Exhibit B2 to estimate the cost of remarriage.

Exhibit B7 displays annuity tables used by NCCI. Separate tables are included for Total Population, Female Population, and Remarriage Annuities. These tables are not included in a typical NCCI filing.

The calculation of the remaining subgroups and the pre-law and post-law benefits invoke the same methodology as described above. Therefore, we have not included these as exhibits.

EXHIBIT I

Summary of Principal Benefit Changes Due to the Annual
Maximum Weekly Benefit Change, Effective 7-1-89

Fatal	7-1-88	7-1-89
% Rate of Compensation		66 2/3%
Min./Max. Weekly Benefit	\$88.67*/\$354.69+	\$92.80*/\$371.21+
Duration: Widow, Child(ren)		Life or Remarriage To age 18, or 21 if a student
Others		Life
Burial Allowance		\$2,000
Subsequent Injury Fund (non-dependency cases)		\$15,000
Remarriage Award (if no dep. children)		Two year lump sum
Social Security Benefit Offset		W.C. Benefit reduced by 100% Initial S.S. Benefit
Total Disability		
% Rate of Compensation		66 2/3%
Min./Max. Weekly Benefit	\$354.69+	\$371.21+
Duration		Period of disability
Social Security Benefit Offset		W.C. Benefit reduced by 50% Initial S.S. Benefit
Waiting Period/Retroactive after, days		3/14
Minimum Payable (in dep. cases)		6 years of W.C. Benefits
Permanent Partial Disability		
Weekly Benefit: Schedule		Fixed at \$150.00
Non-Schedule		Fixed at \$120.00
Healing Period		Same as Temp. Total
Duration: Schedule		As per Schedule
Non-Schedule		Life Expectancy x % Disability
Maximum Amount Payable:		
Schedule		\$150.00 x Schedule
Non-Schedule		\$37,560
Minimum Payable		Amount determined due

EXHIBIT IX-C

Summary of Social Security Benefits
for Fatal and Permanent Total Disability Cases

(1) Dependency	(2) Payee	(3) Fraction of Primary Payable*	(4) Conditions of Payment
Widow Alone	Widow	100%	Age 65
Widow Alone	Widow	82.9	Age 62
Widow Alone	Widow	71.5	Age 60
Widow and Children	Widow	75	While caring for child under age 18
	Each Child	75	Until age 18, or 19 if a student
Orphans	Each Child	75	Until age 18, or 19 if a student
One Parent	Parent	82.5	Age 62
Two Parents	Parents	150	Age 62
PERMANENT TOTAL DISABILITY +			
Worker Alone	Worker	100	After a five month waiting period**
Worker and Wife	Worker	100	After a five month waiting period**
	Wife	50	Age 65
	Wife	37.5	Age 62
Worker, Wife and Children	Worker	100	After a five month waiting period**
	Wife	50	While caring for child, under 18
	Each Child	50	19 if a student
Worker and Children	Worker	100	After a five month waiting period**
	Each Child	50	Until age 18, or 19 if a student

All aggregate benefits are limited to the family maximum benefit. The five month waiting period also applies to members of the worker's family.

At age 65 the disability benefit becomes a retirement benefit.

**LAW AMENDMENTS:
TECHNICAL APPENDIX C**

PERMANENT TOTAL INJURIES

The purpose of this Appendix is to describe the details of the methodology employed by NCCI in pricing permanent total (PT) disability benefits.

Exhibit C1, Sheets 1-2 display NCCI's summary of the benefit provisions and the law amendment change including a summary of social security benefits for PT disability cases for a sample benefit revision. For this revision, the only change is an increase in the maximum weekly benefit from \$354.69 to \$371.21.

Exhibit C2 summarizes the calculation of the effect of the law amendment change on permanent total disability benefits. Lines 1-4 represent four distinct subgroups of the permanent total disability benefit which NCCI prices. These four subgroups represent different combinations of dependency; (1) worker alone, (2) worker with wife (and no children), (3) worker with children (and no wife), and (4) worker with wife and children.

The cost in dollars, both pre and post-law amendment, is estimated for each subgroup. The total PT cost is shown in line 5. Line 6 is the overall effect of the law change, that is, the total cost in dollars based on the new law divided by the total cost in dollars based on the old law.

Exhibit C3 is an example of the NCCI calculation of PT benefits for the first subgroup, injured worker alone, using the pre-law benefits. The calculations of the post-law benefits use the same methodology and, thus, are not included.

Column (1) is the year(s) in which the annuity benefit applies. This time line corresponds to changes in the workers compensation benefits, due to changes in the social security benefits or changes in the status of dependent child(ren), if applicable. On this exhibit, the full workers compensation benefit applies for 5 months, followed by a reduced benefit (based on a social security offset) for life. The worker is immediately eligible for the permanent total workers compensation benefit, but there is a 5 month waiting period until the social security total disability benefits apply.

LAW AMENDMENTS: TECHNICAL APPENDIX C

Column (2) displays the type of annuity in effect during the year(s) indicated in column (1). (Note that the average age of the injured worker and dependents for each subgroup are derived from data underlying the Workmen's Compensation Injury Table.) The benefit costs for a worker alone, assuming an average age of 46, are defined by a 5 month term life annuity (5 months equals .4167 years) for a person age 46 (when the worker receives only the workers compensation benefits) and a 5 month deferred life annuity for this same person (when the worker receives social security benefits and a reduced workers compensation benefit).

Note that NCCI calculates a single annuity for a person of average age (46 years old, in this case.) However, there is actually a distribution of ages around this average. The average of annuities for people of various ages differs from the annuity of a single person of average age.

In cases where a life annuity is used, NCCI makes an adjustment to the average age to help counteract this potential distortion. In these cases, NCCI uses a "pension" average age instead of an arithmetic average age.

For example, on Exhibit 8, Sheet 4 in the main report, NCCI calculates four average ages for PT cases.

Arithmetic	46
Pension	47
Pension 5% Escalation	44
Pension 6% Escalation	43

Column (3) contains the present value of an annuity of a unit benefit based on a 3.5% interest rate and the NCCI mortality table (United States, 1979-81 Life Table for the Total Population). The interest rate and mortality table are not displayed in a typical filing.

Column (4) is the amount of the average weekly social security benefit. This has been calculated based on NCCI's interpretation of the social security benefit structure. (Exhibit C5).

LAW AMENDMENTS: TECHNICAL APPENDIX C

Column (5) calculates the weekly benefit during each of the annuity intervals. The full benefit of \$234.87 is based on the statewide average weekly wage (SAWW), the minimum and maximum weekly benefits, and the wage table. Its derivation is not shown here. (Sample calculations of average weekly benefits using NCCI's formulas appear in Appendix E.) The reduced workers compensation benefit in Line 2 is based on the full workers compensation benefit reduced by half of the social security benefit (The 50% reduction appears on Exhibit C1, Sheet 1.)

Column (6) is the PT benefit cost associated with each annuity period computed by multiplying columns (3) and (5).

Line 7 is the total PT cost per case for this subgroup, injured workers alone.

Line 8 is the average number of cases out of every 1,000 cases with workers alone. (This is based on the Workmen's Compensation Injury Table.)

Line 9 is the total cost in dollars for this subgroup.

Exhibit C4 is an example of the NCCI calculation of PT benefits for the second subgroup, injured worker with wife, using the pre-law benefits. Again, the post-law benefit calculation is similar. Column (1) through line 9 have the same definition as in Exhibit C3 for the injured worker alone. The worker is assumed to be 54 years old.

A description of the various annuities shown in column (2) corresponding to each year in column (1) follows. The first annuity is an annuity certain for 21.67 weeks corresponding to the 5 month waiting period required by social security. In other words, during this time period, the worker receives full workers compensation benefits.

The second annuity is a 21.67 week deferred annuity certain for 446.88 weeks. The statute requires that 6 years of workers compensation benefits be paid. After 5 months the workers compensation benefit is reduced by half of the social security benefit. NCCI calculates that 9.0106 years of total workers compensation benefits consisting of full benefits (for 5 months) and reduced benefits (for the remaining

LAW AMENDMENTS: TECHNICAL APPENDIX C

period) is equivalent to 6 years of full benefits. The derivation of the 9.0106 years appears in the notes to this exhibit.

The third annuity is a deferred life annuity for a period of 1.9894 years. (At which point in time, we are 11 years past the date of injury, $11 = 1.9894 + 9.0106$). The annuity has converted to a life annuity, as opposed to an annuity certain, but the social security benefit is the same as in the previous line.

The last annuity is an 11 year deferred life annuity for the remainder of the injured worker's life. At this point, the worker's wife has reached age 62, and the social security benefit increases by 37.5% from 164.56 per week to 226.27 per week.

Exhibit C5 is an example of NCCI's determination of the average social security weekly benefits for disability cases. Line A is the effective average annual indexed wage based on NCCI's history of statewide average weekly wages over a 24 year period. The social security law provides for the elimination of the five lowest annual wages. Line B is the effective average indexed monthly wage (AIMW), that is line A divide by 12. Line C is the primary insurance amount (PIA) derived as the sum of 90% of the first \$339 of AIMW, 32% of the next \$1,705 of AIMW and 15% of any remaining AIMW over \$2,044. Line D is the maximum monthly family benefit derived using various percentages of the AIMW and the PIA. The exact formula is shown in the exhibit. Line E is the primary weekly benefit, that is the primary monthly benefit in line C converted to a weekly benefit. Line F is the maximum weekly family benefit, that is, the maximum monthly family benefit from line D converted to a weekly benefit.

EXHIBIT I

Summary of Principal Benefit Changes Due to the Annual
Maximum Weekly Benefit Change, Effective 7-1-89

Fatal	7-1-88	7-1-89
% Rate of Compensation		66 2/3%
Min./Max. Weekly Benefit	\$88.67*/\$354.69+	\$92.80*/\$371.21+
Duration: Widow, Child(ren)		Life or Remarriage To age 18, or 21 if a student
Others		Life
Burial Allowance		\$2,000
Subsequent Injury Fund (non-dependency cases)		\$15,000
Remarriage Award (if no dep. children)		Two year lump sum
Social Security Benefit Offset		W.C. Benefit reduced by 100% Initial S.S. Benefit
Total Disability		
% Rate of Compensation		66 2/3%
Min./Max. Weekly Benefit	\$354.69+	\$371.21+
Duration		Period of disability
Social Security Benefit Offset		W.C. Benefit reduced by 50% Initial S.S. Benefit
Waiting Period/Retroactive after, days		3/14
Minimum Payable (in dep. cases)		6 years of W.C. Benefits
Permanent Partial Disability		
Weekly Benefit: Schedule		Fixed at \$150.00
Non-Schedule		Fixed at \$120.00
Healing Period		Same as Temp. Total
Duration: Schedule		As per Schedule
Non-Schedule		Life Expectancy x % Disability
Maximum Amount Payable: Schedule		\$150.00 x Schedule
Non-Schedule		\$37,560
Minimum Payable		Amount determined due

EXHIBIT IX-C

Summary of Social Security Benefits
for Fatal and Permanent Total Disability Cases

A. FATAL

(1) Dependency	(2) Payee	(3) Fraction of Primary Payable*	(4) Conditions of Payment
Widow Alone	Widow	100%	Age 65
Widow Alone	Widow	82.9	Age 62
Widow Alone	Widow	71.5	Age 60
Widow and Children	Widow	75	While caring for child under age 18
	Each Child	75	Until age 18, or 19 if a student
Orphans	Each Child	75	Until age 18, or 19 if a student
One Parent	Parent	82.5	Age 62
Two Parents	Parents	150	Age 62

B. PERMANENT TOTAL DISABILITY +

Worker Alone	Worker	100	After a five month waiting period**
Worker and Wife	Worker	100	After a five month waiting period**
	Wife	50	Age 65
	Wife	37.5	Age 62
Worker, Wife and Children	Worker	100	After a five month waiting period**
	Wife	50	While caring for child, under 18
	Each Child	50	19 if a student
	Each Child	50	Until age 18, or 19 if a student
Worker and Children	Worker	100	After a five month waiting period**
	Each Child	50	Until age 18, or 19 if a student

- * All aggregate benefits are limited to the family maximum benefit.
- * The five month waiting period also applies to members of the worker's family.
- At age 65 the disability benefit becomes a retirement benefit.

Determination of the Average Social Security Weekly Benefits

	<u>Disability</u>	<u>Survivorship or Retirement</u>
A. Effective Average Indexed Annual Wage*	19,379.95	19,379.95
B. Effective Average Indexed Monthly Wage = (A)/12**	1,614.00	1,614.00
C. Primary Insurance Amount for 07/01/89***	713.10	713.10
D. Maximum Monthly Family Benefit for 07/01/89****	1,069.65	1,291.10
E. Primary Weekly Benefit = [(C)x12]/52	164.56	164.56
F. Maximum Weekly Family Benefit = [(D)x12]/52	246.84	297.95

* The sum of the 19 greatest "Effective Annual Indexed Wages" (from Exhibit IX-A), divided by 19.

** Any fraction of a dollar is dropped.

*** The Primary Insurance Amount for workers becoming eligible after 07/01/89 is derived as the sum of the following:

90% of the first \$339 of the Average Indexed Monthly Wage	305.10
32% of the next \$1,705 of the Average Indexed Monthly Wage	408.00
15% of any amount over \$2,044 of the A.I.M.W.	<u>0.00</u>

Any fraction of a dime is dropped from the total. 713.10

*** The Maximum Family Benefit for disabled workers is derived as the lesser of:

- (1) 85% of the A.I.M.W. (\$1,371.90) or 100% of the P.I.A. (\$713.10), whichever is greater, and:
- (2) 150% of the P.I.A. (\$1,069.65).

The Maximum Family Benefit for retired workers is derived as the sum of the following:

150% of the P.I.A. less than \$433	649.50
272% of the P.I.A. greater than \$433 and less than \$626	524.96
134% of the P.I.A. greater than \$626 and less than \$816	116.71
175% of the P.I.A. greater than \$816	<u>0.00</u>

Any fraction of a dime is dropped from the total. 1,291.10

**LAW AMENDMENTS:
TECHNICAL APPENDIX D**

TEMPORARY TOTAL INJURIES

This Appendix describes the detailed calculations underlying a sample NCCI benefit pricing for temporary total (TT) disability.

Exhibit D1, Sheet 1 displays NCCI's summary of the benefit provisions and the law amendment change for TT disability cases. The only change in the benefit structure is an increase in the maximum weekly benefit from \$354.69 per week to \$371.21 per week.

Exhibit D2, Sheets 1-2 show the distribution of durations for these claims based on the injury table.

For purposes of this Appendix we will assume that the calculation of the average weekly workers compensation benefits have been computed elsewhere in accordance with the statutory provisions and NCCI's estimate of the state average weekly wage (SAWW). Sample calculations of average weekly benefits using NCCI's formulas appear in Appendix E.

Exhibit D3 is NCCI's exhibit for the calculation of the effect of the law amendment change on temporary total disability benefits. Line 1 is the statutory waiting period, that is, the required number of days lost before TT benefits become available, based on pre and post-law amendment. In this exhibit there is no change in the waiting period. Line 2 is the retroactive period, that is, the minimum number of days lost after which the injured worker can recoup the TT benefits for the waiting period.

Line 3 is the total days of disability based on the cases which exceed the waiting period from line 1. This represents the average number of days for which TT benefits will be paid. This number is the entry in column (4) from Exhibit D2, Sheet 1 corresponding to the disability period lasting 4 days or longer.

Line 4 of Exhibit D3 is the total number of cases which exceed the retroactive period and, therefore, can recoup TT benefits for the waiting period. This number is the entry in column (3) from Exhibit D2, Sheet 1 corresponding to the disability period lasting 15 days or longer. Given 39,245 cases that exceed the retroactive period, then

**LAW AMENDMENTS:
TECHNICAL APPENDIX D**

the additional number of benefit days is the length of the waiting period (3) times the number of cases (39,245). This is the calculation that appears in Line 5.

Line 6 is the total days of TT benefits payable, that is, the sum of line 3 and line 5. That is, the total number of benefit days for all cases that exceed three days in duration, plus the additional days of benefits for the cases that exceed the retroactive period.

Line 7 is line 6 divided by 7, that is the total weeks of TT benefits payable. Line 8 is the average weekly temporary total benefit. This has been calculated based on the statewide average weekly wage (SAWW), the minimum and maximum weekly benefits, and the wage table. Its derivation is not shown here. (Sample calculations of average weekly benefits using NCCI's formulas appear in Appendix E.) Note that the average weekly benefit changes from the old law to the new law, while all the duration statistics are identical under the old law and the new law.

Line 9 is the total cost in dollars for TT benefits, that is, the product of line 7 and line 8. Line 10 is the overall effect of the law change on temporary total disability costs, that is, the total cost in dollars based on the new law divided by the total cost in dollars based on the old law.

TECHNICAL APPENDIX E**

PERMANENT PARTIAL INJURIES

This Appendix describes the detailed calculations underlying a sample NCCI benefit pricing for major permanent partial claims. It is divided into six sections:

- A. Scheduled Injuries
- B. Non-Scheduled Injuries
- C. Healing Period
- D. Summary
- E. Lump Sums
- F. Comparison of Model Pricing to Other Data

A. Scheduled Injury Benefit Calculation Details

This part illustrates the NCCI detailed calculations for a sample state.

Exhibit E1 summarizes a typical NCCI calculation of a permanent partial benefit change pricing. Lines 1, 3, 5, and 11 (E1, Sheet 1 for major permanent partial E1, Sheet 2 for minor permanent partial) are derived from Exhibit E2 (Sheet 1 for major, Sheets 2-3 for minor) and are the estimated number of weeks of benefits for various components of the permanent partial benefit package.

Exhibit E2, Sheet 1 summarizes a typical NCCI calculation of their evaluation of permanent partial law changes. This exhibit displays the derivation of the number of weeks of benefits for scheduled permanent partial and healing period benefits. Columns 2, 3, and 8 of Exhibit E2 are based on the NCCI injury tables.

Column (1) of Exhibit E2, Sheet 1 lists the types of scheduled injuries that are contained in many workers compensation statutes. For states, that have a less exhaustive list of scheduled injuries, this table is collapsed into a smaller table. Conversely, for states, that have a more comprehensive list of scheduled injuries, this table is expanded into a larger table. For example, in a state in which back injuries are scheduled injuries, this item would be included part A of Exhibit E2, Sheet 1 and the part B, other major injuries, total would be decreased.

LAW AMENDMENTS: TECHNICAL APPENDIX E

Column (2) of Exhibit E2, case frequency, gives a frequency of the injuries. For example, from this table we see that for state X, 50.3% (503 / 1,000) of major permanent partial injuries are scheduled injuries. Also, 0.05% (5 / 1,000) of major permanent partial injuries are due to the dismemberment of a hand. The distribution of frequency by injury type is derived from the injury table.

Column (3) of Exhibit E2, average percentage loss, is derived from the NCCI injury tables. The percentage loss refers to the percentage loss for that particular member or organ. Therefore, amputation results in 100% loss. For loss of use, the percentage loss of use of that member is also based on the NCCI injury table. The figures in column (4), schedule at 100%, are based on the state statute. For example, some state statutes indicate that for the partial loss of use of an arm, hand, thumb, finger, leg, foot, toe or phalanges, compensation shall be paid for the proportionate loss of the use of such arm, hand, thumb, finger, leg foot, toe or phalanges. Other states may define a specific benefit for partial loss of use. For example, in our sample state X, we see that the figures in column (4) for partial loss of use are 50% of the figure for total loss of use. This relationship is based on the terms of the statute. The NCCI does not typically provide the details underlying their calculations.

Column (5) is the product of columns (3) and (4). That is, it represents the total number of weeks of permanent partial benefits payable based on the injury schedule, for both total loss of use of various members and partial loss of use.

Column (6) is column (5) discounted for interest only for durations that are longer than 52 weeks, while shorter durations are undiscounted.

The figures in column (7), weeks payable for schedule, is the product of column (2) times column (6). This product for a particular injury represents the discounted number of weeks that would have to be paid in permanent partial benefits for this group of 1,000 permanent partial injuries. For example, from Exhibit E2, Sheet 1, we see that for State X, on average out of every 1,000 major permanent partial injuries 5 will be for dismembered hands. For state X, a worker who has sustained such a hand injury will receive 195 weeks of permanent partial benefits or on a commuted basis, 182.98 weeks. Therefore, out of every 1,000 major permanent partial injuries, 915

LAW AMENDMENTS: TECHNICAL APPENDIX E

commuted weeks of benefits will be due to dismembered hand injuries ($915 = 5 \times 183$). Also, from this exhibit we see that on the average out of every 1,000 major permanent partial injuries, a grand total of 51,984 commuted weeks of benefits will be paid for scheduled injuries.

Column (8), average healing period, indicates, for each type of injury, the healing period associated with the injury. This distribution is based on the Injury Table. Finally, column (9), weeks payable for healing period, gives an estimate of the number of weeks that benefits must be paid for the healing period. For example, for dismembered hands, out of every 1,000 major permanent partial injuries, the employers of state X would be liable for 145 weeks of healing period benefits, i.e., 145 weeks of temporary total benefits. In some states healing period benefits are an add on to the permanent partial scheduled benefits, as is the case for our sample state. In other states they may be subtracted from the duration of permanent partial benefits. Other combinations are also possible. For example, some states limit the combined duration of healing period and permanent partial benefits. Any of these combinations could be reflected on this exhibit. However, in case of a limit on the combined duration of healing period and permanent partial benefits, care must be taken to properly calculate the effect. For example, if there is a limitation of 250 weeks on the combined benefits, the average limited benefit is not the sum of the limited sum of the component parts.

Finally, from the summary of part A on Exhibit E2, Sheet 1, we see that NCCI estimates that out of every 1,000 major permanent partial injuries, 503 will be scheduled injuries producing on the average 103.35 ($103.35 = 51,984 / 503$) weeks of scheduled benefits and on average 25.76 ($25.76 = 12,956 / 503$) weeks for healing period.

B. Permanent Partial Non-Scheduled Injuries

Part B of this exhibit displays the information on permanent partial non-scheduled injuries. For this sample state, we see that out of every 1,000 major permanent partial injuries, 497 are estimated to be non-scheduled injuries producing on the average 36 weeks of healing period. (Note that this average healing period is greater than the

LAW AMENDMENTS: TECHNICAL APPENDIX E

average healing period for scheduled injuries.) Also, NCCI will assume that for the major permanent partial non-scheduled injuries these injuries will produce, on the average, a 40% wage loss. These amounts are also derived from the injury table. For this sample state, the duration of permanent partial benefits for non-scheduled injuries are calculated on another exhibit, using annuity functions. Possible approaches we have seen in other states include a 40% wage loss for the maximum duration of permanent partial benefits, or the use of external data sources to estimate durations.

The average weekly benefit is calculated in a similar manner throughout the NCCI benefit pricing structure. That is, the following elements are used:

- a. Compensation Rate (typically 66 2/3%, but for this sample state it will be 50%, 55%, 67%, or 75% depending on the type of benefit)
- b. Statewide Average Weekly Wage
- c. Minimum and Maximum Benefits
- d. Wage Table

We will now review Exhibit E3, which calculates average weekly benefits in more detail. Lines 2 and 3 give the date of the law change and the percentage rate of compensation for this type of injury. In this case, it is 55% of the injured employee's average weekly wage. The percentage is set by statute. Also, lines 4 and 5 are set by statute. For state X, as of 10/1/88, the maximum weekly benefit payable will be \$380.77 and the minimum benefit will be \$0.00.

Line 9 is calculated by NCCI from the Current Population Survey. (See Section III, Subsection B of the main report.) Lines 10 through line 13 are self explanatory. Lines 14, 15, 17, and 18 are derived from the wage table. Line 22 which is the sum of lines 16, 20, and 21, displays the limit factor. This factor indicates that because state X will limit the injured employee's wage to no more than \$380.77 in the calculation of his workers compensation benefit, the state's average weekly wage should be modified by the factor 0.8556. Then finally in line 24, an estimate of the average weekly benefit is calculated as the effective average weekly wage (\$353.07) times the rate of

LAW AMENDMENTS: TECHNICAL APPENDIX E

compensation (55%). The effective average weekly wage is the actual average weekly wages times the limit factor.

Repeating the above calculations for the different rates of compensation for the scheduled major permanent partial injuries, we are able to complete part A of Exhibit E1. In line 7 of Exhibit E1, Sheet 1, we see that under the old law, an estimate of the benefit costs for the 1,000 the scheduled major permanent partial injuries would be \$8,642,589 and under the new law the cost for these same injuries would be \$8,949,497. One must be careful, how one interprets this number. The NCCI is not suggesting that the total cost to state X for these benefits is \$8.6 million under the old law and \$8.9 million under the new law. Rather, the NCCI is constructing a model of the benefit structure. The proper interpretation is that for the 503 injuries that comprise the table of scheduled injuries, the total cost under the old system would be approximately \$8.6 million and under the new law the cost would be \$8.9 million. Another possible way to interpret these numbers is to say that under the old system an estimate of the average cost per scheduled injury would be \$17,182 ($8,642,589 / 503$) and an estimate of the average cost per scheduled injury under the new law would be \$17,792 ($8,949,497 / 503$).

Returning to Exhibit E1, Sheet 1, line 10 is the product of line 8 times line 9. Line 10 should be interpreted as follows: On average, out of every 1,000 major permanent partial injuries, \$23,580,246 will be paid for non-scheduled injuries benefits under the old law and on average, out of every 1,000 major permanent partial injuries, \$23,601,596 will be paid for non-scheduled injuries under the new law, (i.e., average costs of \$47,445 ($23,580,246/497$) under the old law and \$47,488 ($23,601,596/497$) under the new law).

For the sample state, non-scheduled permanent partial injuries are compensated based on wage loss. Since there is an assumed 40% wage loss for major injuries (based on the injury table), and by statute, the injured employee is entitled to a lifetime weekly benefit equal to 55% of his wage loss, the calculated benefit is 22% ($.22 = .55 \times .40$) of his average weekly wage. (The lifetime benefit is not readily apparent from the NCCI summary of benefits.) The 40% wage loss assumption is probably not critical in this situation since the same percentage is used in the pre and post law change calculations. (The exact size of the wage loss assumption will usually

**LAW AMENDMENTS:
TECHNICAL APPENDIX E**

only affect the weights attributable to non-scheduled as compared to scheduled injuries. In this sample state, approximately 60% of the major permanent partial benefits are considered to be non-scheduled and the estimated change in the cost of non-scheduled benefits is +0.1%. Meanwhile the scheduled benefits and the healing period benefits comprise approximately 40% of the total costs and are estimated to increase by +3.6%.) In a situation where there would be a change in the method of compensating non-scheduled benefits, we would consider this a non-formula change. However, NCCI may still include this variation as a formula change.

From Exhibit E2, Sheet 1, we see that out of every 1,000 major permanent partial injuries, 497 of the injuries are estimated to be non-scheduled injuries. For these, non-scheduled injuries the average healing period will be 36 weeks. So after the 36 weeks, the employee will be entitled to permanent partial benefits for life. Therefore, under this scenario, NCCI needs to estimate the average number of weeks of benefits that will be paid. To make this estimation, NCCI assumes that the average age when injured of an employee with a major permanent partial non-scheduled injury is 37 years old. This average age is from an analysis by NCCI of its injury tables. NCCI then calculates that the average life expectancy of a 37 year old is 2,057.14 weeks (approximately 40 years). The life expectancy is derived from the 1979 Total Population Life Tables.

Next, NCCI calculates a duration of benefits of 15.5472 years using the following formula:

$$15.5472 = [(2,057.14 - 36) \times .40 / 52]$$

where:

the 2,057.14 is the life expectancy in weeks,

the 36 refers to the average healing period for non-scheduled major permanent partial in weeks,

the .40 represents the average duration of loss of earning capacity benefits as a percent of the maximum possible duration, and

LAW AMENDMENTS: TECHNICAL APPENDIX E

the 52 divisor converts weeks to years.

According to NCCI, the .40 factor to adjust durations was based on a special countrywide call for wage loss data that compared the average duration of wage loss claims to the average statutory maximum. Coincidentally, the .40 is also the factor that represents the average wage loss for major permanent partial claims. In addition, for permanent partial minor claims, a .25 factor is used for both the average wage loss and the average duration adjustment. Based on the NCCI formula, the annuity formula for a permanent partial major non-scheduled injury stream of benefits would be Y , where Y is defined as an annuity for a person age 37 continuous for 15.5472 years. Finally, we see that out of 1,000 major permanent partial injuries on the average, 305,009 ($305,009 = 497 \times Y \times 52$) weeks of benefits will be payable for non-scheduled injuries. This is the number appearing on line 8, of Exhibit E1, Sheet 1. The annuity tables used to calculate Y are the 1979 Total Population Annuity Value Tables with interest rate of 3.5% and an escalation rate of 0.00% per annum. The interest rate used is a standard value for benefit evaluations and the escalation rates are based on the statutory provision for escalation of workers compensation benefits.

The calculation of the average weekly benefit for non-scheduled injuries, (Exhibit E1, Sheet 1, line 9), is similar to the calculation for scheduled injuries except for one departure. As mentioned above, by statute the benefits for non-scheduled injuries is 55% of wage loss, NCCI uses the number 22% ($.22 = .55 \times .40$) for the nominal rate of compensation. This is based on the assumption of a 40% wage loss for major permanent partial injuries. So for state X, this results in an average weekly benefit pre-law change of \$77.31. Post-law change the average weekly benefit is estimated to be \$77.38 (Exhibit E1, Sheet 1, line 9).

NCCI is not calculating the average benefit based on a 40% wage loss and a benefit percentage of 55% times actual wage loss. Instead, NCCI is calculating the average benefit for a worker who receives a 22% ($40\% \times 55\%$) benefit times their full wage rate. There are two complications with the NCCI conversion both related to how the wage table operates. First of all, by calculating a low benefit rate (22% for major and 13.75% for minor permanent partial), a worker must be very highly paid for the maximum benefit limit to apply. Secondly, the 40% wage loss is assumed to apply

LAW AMENDMENTS: TECHNICAL APPENDIX E

exactly to all workers. However, it is more likely that the wage loss will vary around 40% with some workers having a lower percentage of wage loss and some workers having a higher percentage of wage loss. The NCCI method understates the impact of the maximum weekly benefit increase.

A simplified example may help to clarify the situation. Assume that two workers are each earning 150% of the statewide average weekly wage. Also assume that the benefit percentage is 70% of the workers actual wage loss subject to a maximum benefit of 50% of the statewide average weekly wage.

When both workers suffer a major permanent partial non-scheduled injury, the average benefit depends on the distribution of the wage loss. In Scenario 1, the NCCI method, both workers suffer a 40% wage loss. Both workers have a wage loss of 60% of the SAWW [40% of 150%], and a benefit of 42% of the SAWW [70% of 60%] and the maximum benefit has no effect. In Scenario 2, one worker suffers a 10% wage loss and one worker suffers a 70% wage loss (for an average wage loss of 40%). Worker #1 has a wage loss of 15% of the SAWW (10% of 150%) and worker #2 has a wage loss of 105% (70% of 150%) of the SAWW. Their respective benefits are 10.5% and 73.5%. Therefore, worker #2 should be subject to the wage cap. It appears that the NCCI methodology underestimates the impact of the maximum weekly benefit, which in turn leads to an underestimate of the impact of the law change. While not a difficult problem in the formula area, the lack of data and information on wage loss is a serious problem when trying to price non-formula benefit changes.

The calculations for minor permanent partial non-scheduled injuries are similar to those for major. A key difference is that a 25% wage loss assumption is used instead of the 40% figure used for major.

C. Healing Period Benefits

NCCI first estimates the number of weeks of healing period for their 1,000 typical major permanent partial injuries. See Exhibit E2, Sheet 1, column 9. From this exhibit, we see that for every 1,000 major permanent partial injuries, on the average,

LAW AMENDMENTS: TECHNICAL APPENDIX E

there will be 30,848 weeks payable for healing period. This is the number that appears on line 11 of Exhibit E1, Sheet 1.

The calculation of the average weekly benefit for healing period is similar to the calculation of average weekly benefit for permanent partial scheduled injuries. See Exhibit E11 (old law) and E12 (new law) for these calculations. One must be aware of the fact that the healing period is governed by the temporary total benefit structure and therefore in state X the nominal rate of compensation for the healing period will be 67% of the injured employee's average weekly wage.

So for state X, we can conclude from Exhibit E1, Sheet 1, that, on the average, out of every 1,000 major permanent partial injuries, \$6,212,787 will be paid for healing period benefits under the old law, and, under the new law, on the average, out of every 1,000 major permanent partial injuries, \$6,433,659 will be paid for healing period benefits.

The table below indicates which exhibits display the calculation of the average weekly benefit for each part of the permanent partial package:

<u>Exhibit</u>	<u>Purpose</u>	<u>Compensation Rate</u>
E3	Dismemberment, 100% Loss of Use, Old Law	55%
E4	Dismemberment, 100% Loss of Use, New Law	55%
E5	Partial Loss Of Use, Old Law	50%
E6	Partial Loss Of Use, New Law	50%
E7	Scheduled Permanent Partial, Old Law	75%
E8	Scheduled Permanent Partial, New Law	75%
E9	Non-Scheduled, Major, Old Law	22%
E10	Non-Scheduled, Major, New Law	22%

E12	Total Disability, Healing, New Law	67%
E13	Non-Scheduled, Minor, Old Law	13.75%
E14	Non-Scheduled, Minor, New Law	13.75%

LAW AMENDMENTS: TECHNICAL APPENDIX E

D. Summary

In Exhibit E1, Sheet 1, the sum of lines 7, 10, and 13, yields line 14. Line 14, therefore, represents the total benefits payable for the 1,000 major permanent partial injuries. Hence, on average out of every 1,000 major permanent partial injuries \$38,435,622 of benefits will be paid under the old law and, on the average, \$38,984,752 under the new law. Another way of stating this conclusion is as follows: An estimate of the average cost of benefits under the old law is \$38,435.62 ($38,435.62 = 38,435,622 / 1,000$) and is \$38,984.75 under the new law. Therefore, an estimate of the change in the average benefit costs would be 1.014 ($1.014 = 38,984.75 / 38,435.62$).

E. Lump Sums

NCCI's benefit pricing model attempts to estimate the average cost of benefits based on the statutory structure of the law. They reflect lump summing of claims to a limited extent in that scheduled permanent partial claims greater than 52 weeks in duration are assumed to be commuted. However, in many states, the lump summing of claims is an important issue and states sometimes adjust their systems to make the lump summing of claims more difficult or easier, depending on the perceived problems in the state. The NCCI formula pricing methodology does not give recognition to the prevailing lump summing approach in the state, and it does not reflect the impact of changes in lump summing.

Lump sums are an important component of how workers compensation claims are settled. Depending on other factors in the environment, states may consider that too many cases are being lump summed, and that the use of lump sums should be discouraged. In other circumstances, states may wish to encourage the use of lump sum settlements, for example when there is a large backlog in the administrative inventory of claims awaiting processing.

Therefore, legislation often addresses the use of lump sum settlements.

LAW AMENDMENTS: TECHNICAL APPENDIX E

Insurers utilize lump sum settlements for a variety of reasons. In some states they may be the only way to be reasonably sure of terminating benefits. In other states, the use of lump sum settlements may be advantageous to the company to release themselves from future liability on the claim and avoid the risk of an adverse outcome, (similar to the settlement of a liability claim). A discussion of all the reasons for and cost impacts of lump sum settlements is beyond the scope of our assignment. However, in this section we will point out some of the impacts that lump sums have on the benefit evaluation process.

1. Where are lump sums currently reflected in the benefit evaluation formulas?

In the current benefit pricing formulas lump sum values are not generally used. However, certain benefit components are evaluated by the use of annuities, which are discounted at a 3.5% interest rate. In addition, scheduled permanent partial benefits over 52 weeks in duration are "commuted". That is, they are discounted for interest at a 3.5% rate.

The choice of a 3.5% interest rate derives from statutory reserving requirements and is not intended to reflect market interest rates. When an insurer is evaluating the merits of a lump sum settlement they are likely to select an interest rate based on their evaluation of current and future interest rates. For an individual case, the present value at a 3.5% rate compared to the present value at a 6.0% rate may be substantially different. This should have only a small impact on the formula benefit calculation, where the interest rate will only affect the weights assigned in the pricing calculation. However, in a non-formula situation the impact may be more substantial.

2. What are some of the areas where lump sums may affect data reported to NCCI?

As noted above, an insurer may use a lump sum settlement to release themselves from future liability on the claim and avoid the risk of an adverse outcome. When the insurer reports this loss experience to NCCI, the claim will have a reduced value based on the interest discount and the probability value reflecting the chance of an adverse outcome. In most cases, the lump sum will be reported as a permanent partial. This indicates that, absent lump sums, some fraction of the permanent partial

**LAW AMENDMENTS:
TECHNICAL APPENDIX E**

claims would have been permanent total claims. This, in turn, indicates that the benefit structure for permanent total claims will impact on the settlement value of permanent partial claims.

F. Comparison of Model Pricing to Other Data

As noted above, the average benefit cost estimated by NCCI is a model of what the statutory benefit structure is expected to pay for a major permanent partial injury. For the sample state under review, this average is \$38,436 under the old benefit structure. In addition, NCCI gathers WCSP data on the actual cost of major permanent partial injuries. NCCI also has loss development techniques to develop the immature WCSP data to an ultimate value. Therefore, it is possible to compare the estimated benefit cost of an injury based on the formula pricing model to actual data obtained from the WCSP. Such a comparison may be useful in evaluating the performance of the pricing models.

**LAW AMENDMENTS:
TECHNICAL APPENDIX F**

TREND AND BENEFIT ON-LEVEL FACTORS

This appendix will present two alternate trend calculations in a simplified example.

The assumptions underlying both methods are as follows:

- The benefit percentages remain constant through the experience period.
- Average wages increase by 5% per year.
- The 5% average wage increase results in a 5% per year average benefit increase.
- Rate levels are constant.

Set forth below are trend calculations done in year 4 for two methods, based on loss experience through year 3.

Method 1

Year	(1) Payroll	(2) Rate	(3) Premium (1)x(2)/100	(4) Losses	(5) Benefit on Level Factor	(6) On Level Loss Ratio (4)x(5)/(3)
1	100	100	100	50.00	1.158	.579
2	105	100	105	52.50	1.103	.552
3	110.25	100	110.25	55.13	1.05	.525

This method produces a downward trend (of 1/1.05 per year).

Method 2 produces the following table

Year	(1) Payroll	(2) Rate	(3) Premium (1)x(2)/100	(4) Losses	(5) Benefit on Level Factor	(6) On Level Loss Ratio (4)x(5)/(3)
1	100	100	100	50.00	1.0	.500
2	105	100	105	52.50	1.0	.500
3	110.25	100	110.25	55.13	1.0	.500

This method produces no trend and the zero trend is applied to a lower on-level loss ratio.

The projected loss ratio for year 4 in Method 1 is $.500 = (.525 \times (1/1.05))$. For Method 2, the projected on-level loss ratio is also $.500 = (.500 \times (1/1.00))$.

**LAW AMENDMENTS:
TECHNICAL APPENDIX F**

Thus, for year 4, where the benefit change is already in effect, both methods produce identical results. (These calculations are assuming an exponential trend, rather than a linear trend).

However, for year 5, Method 1 projects a loss ratio of $.476 = (5.25 \times 1/1.05^2)$ while Method 2 still projects a loss ratio of .500.

ALTERNATIVE EXPOSURE BASES

I. INTRODUCTION

The exposure base is the fundamental measurement of an insured's exposure to loss. The exposure base is multiplied by the rate specified by the rating manual to derive the manual premium for the insured. The total premium collected during the policy term is the manual premium adjusted for experience rating modifications, premium discount, expense constant and minimum premium considerations, and other rating variables (e.g., schedule and retrospective rating) that may apply.

In most jurisdictions and for most classifications, the current exposure base for workers compensation insurance is unlimited payroll. However, the use of unlimited payroll as the fundamental rating element for workers compensation has been a controversial topic almost from the inception date of this line of insurance. At various times, limited payroll; hours worked; number of employees and several combinations thereof have been espoused as preferred alternatives to unlimited payroll.

Currently the discussion on exposure bases centers on whether or not equity in rating can be enhanced by recognizing wage rate differences among insureds within the same classification. The question becomes more acute when considering employers who may be engaged in the exact same activity in the same work location but who pay significantly different hourly wages to their employees.

As an integral part of its comprehensive examination of the NCCI ratemaking procedures, M&R was engaged to respond to the following two questions:

1. What improvement in rate equity could be expected from a system recognizing wage rates (if available) in addition to unlimited payroll?
2. What additional expenses would be expected from administration of a system using wage rates?

The remainder of this chapter details our analysis, conclusions and recommendations concerning these two issues.

ALTERNATIVE EXPOSURE BASES

ALTERNATIVE EXPOSURE BASES

II. CONCLUSIONS AND RECOMMENDATIONS

This section summarizes our conclusions regarding the two objectives of the alternative exposure base review. Following our conclusions is a summary of recommendations for further consideration by the NAIC.

A. Wage Rate(s) - Equity Impact

A comprehensive review of available research on the issue leads to two conclusions:

- No single exposure base for workers compensation (or any other line of insurance) is ideal for all circumstances.
- A usable exposure base must balance theoretical and practical considerations.

Accepting these two initial findings as principles, we then pursued additional areas of analysis. These included reviewing intuitive exposure base/loss cost correlations, evaluating empirical data compiled for the 1985 M&R study for the State of Oregon and testing the rating system for a number of theoretical insureds. From this supplemental analysis, we conclude the following:

- Unlimited payroll appears to provide the most reasonable compromise between theoretical and practical considerations for most insureds.
- The introduction of the Revised Experience Rating Plan (RERP) will mitigate the premium basis inequities inherent in the current rating system for many insureds.
- A further analysis of insured characteristics indicates that, despite the combined application of unlimited payroll and RERP, theoretical inequities in the rating system can remain. For purposes of this report, we refer to any "unidentifiable" premium disparity remaining after application of all aspects of the rating structure, including experience rating, as residual inequity. By testing the impact of the rating system in various hypothetical situations, we conclude

ALTERNATIVE EXPOSURE BASES

that this residual inequity is most likely to exist for insureds with the following joint characteristics:

They are concentrated in classes with a wide range of verifiable average hourly wages.

The wage variation has no logical relationship to occupational hazard specific to a given type and locale of activity.

The insureds are either too small to qualify for or have low credibility under RERP.

- The residual inequity can be further mitigated through a wage rate recognition plan limited to those classes with a demonstrated problem and with hours worked data readily available and verifiable.

Overall, we do not conclude that recognition of wage rates within the rating structure for all classes of insureds would ultimately improve the equity of the system. It is impossible to identify all who benefit (and all who do not) from such a universal change. However, it is clear that such a universal change would provoke a largely unnecessary disturbance in the workers compensation system with regard to rates and procedures.

B. Wage Rate(s) - Expense Impact

At this time, hours worked or average hourly wages are not collected under the NCCI's Workers Compensation Statistical Plan (WCSP). Additionally, there is no procedure in place for all insureds to internally compile and maintain hours worked records for workers compensation rating purposes. Therefore, any attempt to universally collect such data will affect the record-keeping, data collection and processing, and auditing functions of the insureds, insurers, and NCCI. With this perspective, we offer the following observations:

- The availability, quality, and verifiability of hours worked varies greatly by jurisdiction and type of employment.
-

ALTERNATIVE EXPOSURE BASES

- There is no guarantee that such data would be available or meaningful at any cost for all insureds. The types of employment offering the least likelihood of success are:

Those with a high percentage of salaried employees.

Those with a significant number of employees compensated on commission, piecework, or payment-in-kind bases.

Those involving multi-employer and part-time work situations.

- Hours worked or average hourly wages are most likely to be available and verifiable for employments with a high concentration of unionized workers or situations involving governmental monitoring.
- The incorporation of hours worked or average hourly wage in the WCSP will increase data processing costs at least in the short-term. Three different categories of programs would have to be changed:

Insurance carrier programs for those companies capturing WCSP data on an automated basis.

NCCI data base programs for compiling and maintaining WCSP data.

NCCI ratemaking programs for accessing the WCSP data base.

- Estimates of the additional insured record-keeping and insurer audit costs inherent in capturing hours worked range from +26% to +250% for the affected classes. This does not include the programming costs discussed above.

Overall, we believe that the costs associated with universal collection of hours worked or average hourly wage could be as much as 0.4% to 0.7% of collected premium. Even at that cost, there is no guarantee that the data collected will be accurate and usable. Furthermore, these additional expenses could be concentrated in those

ALTERNATIVE EXPOSURE BASES

employments least likely to realize an equity enhancement through wage rate recognition.

C. Wage Rate(s) - Recommendations

We do recommend judicious use of wage rate recognition plans only for those states and classes of employment identified as having residual inequities after application of RERP to the unlimited payroll exposure base. This recommendation follows the precedent set by the construction class premium adjustment plans filed for use in several states. Specifically, the Massachusetts plan (see Exhibit 4) has, in our opinion, the most desirable characteristics. From our perspective, the wage rate plans should have the following characteristics:

1. The state plans should provide a multi-tiered discount schedule for average hourly wages exceeding a specified level.
2. Initially, it may be necessary to survey employers to determine both reasonable discount schedules and class rate offsets. It may also be necessary to update the surveys while discount class data is being compiled.
3. Ideally, the discount class designation would be captured within the WCSP to permit updating of the discounts and offsets as a part of the ratemaking process.
4. The plan should include a mechanism for indexing the discount thresholds on the basis of wage rate changes for the effected classes.
5. As an absolute qualification standard for the plan, the insured should be responsible for collecting hours worked and average hourly wage in a format that is readily verifiable during the normal course of the payroll audit.
6. Experience modifications should be adjusted to reflect the applicable average hourly wage discount.

Overall, the intent of this recommendation is to introduce wage rate differentials as a refinement of the classification system without creating new inequities or extraordinary

ALTERNATIVE EXPOSURE BASES

expenses. Furthermore, it is intended to limit application of wage rate credits to employers where an identifiable problem may exist; e.g., the construction industry. This industry group has a high population of both union and non-union workers; the situation most likely to result in a residual inequity through use of unlimited payroll. We refer to pages 37 through 40 of this report for a more complete discussion of the recommended procedure for introducing wage rate differentials.

As with any change in a premium allocation procedure, certain insureds will benefit while others will not. Those most likely to benefit will be small high-wage paying employers who can compile hours worked. Those most likely to suffer a premium increase are small low-wage paying employers and small high-wage paying employers who cannot compile hours worked; i.e., those who do not qualify for wage credits or have low credibility under RERP.

The impact on this latter group illustrates a problem that transcends actuarial considerations but has been a point of contention in past discussions of alternative exposure bases. A fundamental societal dilemma is created: should small employers be required to pay more for workers compensation insurance? Although the actuarial justification for such a result may exist, this category of insureds may be the least able to afford the increase. Furthermore, the small employers have relatively limited bargaining power with which to achieve more favorable prices or terms. The unresolved question is whether societal concerns outweigh actuarial equity.

By intent of the NAIC, this study did not entail the compilation and analysis of new empirical data. Instead, we were to rely on data from past studies of exposure bases; the most complete of which were conducted in 1984 and 1985. Given the sensitivity of this issue and the lack of up-to-date, relevant data, the NAIC may want to consider follow-up research on the topic of exposure bases.

We foresee two possible avenues of additional research:

1. Initiation of a comprehensive study such as that undertaken by NCCI in Oregon in 1984. This analysis involved both a compilation of wage data through an employer survey and a review of the NCCI loss experience for the same employers.

ALTERNATIVE EXPOSURE BASES

2. Compilation and review of the actual premium and loss data that has emerged under Florida's Contracting Classification Premium Adjustment Program (CCPAP). This program has been in effect since January 1, 1984.

At this time, we suggest that the latter research alternative be pursued. Concentrating on the premium and loss experience developed under Florida's CCPAP will permit an evaluation of the impact of wage rate recognition under actual market conditions. Although the data may be have limited credibility at this time, we believe that this is a logical starting point for additional work.

Section VI of this report provides a more comprehensive discussion of our recommendations. This section also includes our suggested guidelines for identifying classes for which a wage rate recognition plan may be appropriate. We encourage readers of this report to review Section VI in detail.

ALTERNATIVE EXPOSURE BASES

III. OVERVIEW OF EXPOSURE BASES

A discussion of the evolution of workers compensation exposure bases requires an understanding of the function of the exposure or premium base. An overview of exposure bases is provided in the following excerpt from "Notes on Exposure and Premium Bases," an article by Paul Dorweiler, published in the 1929 Proceedings of the Casualty Actuarial Society:

"The medium most desirable as a premium basis is the one possessing a combination of these two qualifications in the largest degree:

1. Magnitude of Medium should vary with hazard.

It is desirable to have for premium basis an exposure medium whose magnitude varies approximately directly with the hazard when this is measured by the losses. By using a medium which varies directly with the hazard, the total premium may be obtained by multiplying the exposure expressed in units of the premium basis by the rate.

2. The Medium should be practical and preferably already in use.

For measuring the exposure it is desirable to have a medium whose magnitude is readily ascertained and which is already used by the assured for other than insurance purposes. The use of a medium possessing these qualities promotes efficiency, as no additional records are necessary for measuring exposure, and enhances accuracy, as various existing records may be used as a check.

When one considers the many diverse factors which enter into a hazard and the additional factors which enter into the evaluation of a hazard in terms of losses, one might expect that generally it would be impossible to find a medium whose magnitude varies directly with the losses."

Significantly, the 62 year old reference still provides a very accurate description of the role of an exposure base and the problems inherent in selecting the optimal base. In an article titled "Exposure Bases Revisited" that appeared in the 1989 Proceedings of

ALTERNATIVE EXPOSURE BASES

the Casualty Actuarial Society, Amy Bouska was able to further clarify the role of an exposure base:

"It is important to make note of two things that exposure bases are not. First, the exposure base is not the true exposure. The exposure base is a proxy for the true exposure, which we are unable to know both because it is constantly changing and because it is generally a function of a large number of variables...

Second, the exposure base is not a rating variable, although the dividing line between the two is somewhat arbitrary at times. In order to determine the correct manual premium for a risk, it is first necessary to classify the risk, based on whatever the rating variables are for the risk under consideration."

This latter point is very significant for workers compensation since the issues of exposure base and classification refinement have become intertwined and confused.

The actual premium charged for workers compensation can best be illustrated as a function with three key variables (for simplicity we are ignoring expense constants, premium discounts, schedule rating, etc.):

$$\begin{array}{ccccc} \text{number of} & & \text{class rate} & & \text{individual risk} \\ \text{exposure} & \times & \text{per exposure} & \times & \text{experience} \\ \text{base units} & & \text{base unit} & & \text{modifier} \end{array}$$

In this equation, the exposure base approximates the hazard to be insured. The class rate translates this hazard into expected losses for the general category of employment. The experience modifier refines the expected losses to better reflect the characteristics of the specific risk to be insured.

In the 1970's, unlimited payroll was adopted by NCCI as the best available proxy for true hazard for all jurisdictions and most classes. With the exception of two states, unlimited payroll is in use countrywide. The two exception states (i.e., Nevada, which uses limited payroll, and Washington, which uses cents-per-hour) have exclusive state funds.

ALTERNATIVE EXPOSURE BASES

The near universal adoption of unlimited payroll does not indicate universal acceptance of the exposure base by all facets of the workers compensation system. At various times, labor and management groups have suggested alternative premium bases that, from their perspective, provide better hazard measurement. Between 1983 and 1985, these groups prompted a series of analyses that provided further insight into the strengths and weaknesses of unlimited payroll and other possible exposure bases. The most prominent of these studies included the following:

1. NCCI's "Study of Premium Equity by Employer Group" (1984)
2. Future Cost Analysts, Inc.'s "An Equitable Basis for Workers Compensation Premiums" (January 1985)
3. M&R's "Review of Alternative Premium Bases for Oregon Workers Compensation Insurance" (March 1985)

As a result of these studies, several states determined that an inequity in the premiums existed between certain categories of low and high average wage construction industry employers. Three different plans to address this problem were implemented:

1. In Florida, a Contracting Classification Premium Adjustment Program (CCPAP) was implemented in January 1984. This program provides for credits from manual premium for average hourly wage rates above \$9.99. A qualifying contracting employer can receive a maximum credit of 25%. The average hourly wage rate thresholds have not changed since implementation.
2. In Maryland, Oregon, Illinois, and Nebraska a Loss Ratio Adjustment Program (LRAP) was implemented effective July 1985. This program provided for an increase in the sensitivity of the experience rating modification to the actual experience of construction insureds. The program only applied to experience rated risks.
3. In California, several construction classes were split into two groups based on an average hourly wage threshold. This plan is commonly referred to as a two-tier plan.

ALTERNATIVE EXPOSURE BASES

Since 1985, there have been several new developments pertaining to exposure bases:

1. LRAP was replaced by RERP in Nebraska (November 1989), Maryland (July 1990), Illinois (September 1990), and Oregon (March 1991). This change was consistent with NCCI's original concept of LRAP as an interim measure for contractors that would be superseded by a more responsive experience rating plan for all classes of insureds.
2. Variations on CCPAP were filed in 1990 and 1991 in Delaware, Massachusetts, Missouri, Oregon, and Pennsylvania. Again, only contractors were affected.
3. A review of alternatives to unlimited payroll was initiated in New Mexico in 1990. A new effort was also undertaken in Oregon, site of the most complete analysis done in recent years. At this time, we understand that neither review has been completed.

To date, no definitive information regarding the success or failure of the wage plans implemented in the 1980's has been compiled. However, based on conversations with individuals most familiar with the Florida experience, we draw the following observations concerning the CCPAP approach:

- The proportion of risks receiving discounts has not increased significantly over time despite the fact that the wage thresholds have not been indexed,
- Although the class rate offsets caused by the CCPAP have been monitored and adjusted, no test of the adequacy or equity of discounts has been conducted, and
- The program appears to have addressed the primary equity concerns of the construction industry without requiring a massive change in the Florida workers compensation rating system.

Given the most recent level of activity and interest in this area, it is clear that many questions regarding the optimal exposure base for workers compensation remain unresolved.

ALTERNATIVE EXPOSURE BASES

IV. EVALUATION OF WAGE RATE(S) RECOGNITION (OBJECTIVE 6a)

The objective of this aspect of the examination was to evaluate the improvement, if any, in rate equity that could be realized through recognition of wage rates (when available) as a supplement to the unlimited payroll premium base. The scope of the assignment did not involve collection and compilation of original data. Instead, we relied on data compiled from past studies of alternative exposure bases.

A. Data Sources

Our research indicates that the most comprehensive data base pertaining to workers compensation exposure bases was compiled during the 1983 through 1985 period in conjunction with studies done for Florida and Oregon. Of particular value was information collected for the 1984 NCCI "Study of Premium Equity by Employer Group." This included actual Oregon premium and loss data by employer for 42 construction classifications. The data were compiled for 1983 Oregon employers surveyed by the research firm of Bardsley & Haslacher, Inc. The survey was necessary to determine employer characteristics not captured in NCCI statistics. The key characteristics included average weekly wages, number of employees and union/non-union status.

Subsequent to release of the 1984 NCCI study, M&R was retained by the Oregon Workers Compensation Department to conduct a follow-up analysis. This latter study, titled "Review of Alternative Premium Bases for Oregon Workers Compensation Insurance" (March 1985), involved review of NCCI findings and analysis of supplemental data compiled from the NCCI records. This supplemental information provided the primary data base for the current M&R review.

In addition to the two studies mentioned (copies of both can be found in the Technical Supplement), we drew upon the analyses and observations derived from the following studies:

ALTERNATIVE EXPOSURE BASES

1. Future Cost Analysts, Inc.'s "An Equitable Basis for Workers Compensation Premiums" (January 1985)
2. Future Cost Analysts, Inc.'s "A Response to: 'Study of Premium Equity by Employer Groups'"
3. NCCI's "Workers Compensation Premium: Finding the Perfect Fit" (1985)
4. NCCI's "The Basis of Premium for Workers Compensation Insurance"
5. NCCI's "Understanding the Changes Introduced by the Revised Workers Compensation Experience Rating Plan" (November 1989)

In addition, NCCI provided to us several rate filings and compilations from the Detailed Claims Information (DCI) data base.

B. Analysis

Many different exposure bases for workers compensation have been considered and proposed over time. Although a full analysis of all such alternatives is beyond the scope of this assignment, a brief review of these options and their perceived strengths and weaknesses will facilitate putting the wage rate(s) issue into perspective. The following grid is offered as a means of considering alternative exposure bases and their correlation with the components of workers compensation costs. Included within the table is our judgmental evaluation of each exposure medium as it relates to each cost component.

ALTERNATIVE EXPOSURE BASES

EXPOSURE BASE/COST COMPONENT MATRIX

<u>Exposure Base</u>	<u>Number of Claims</u>	<u>Medical Costs</u>		<u>Indemnity Costs</u>		<u>Vocational Rehabilitation</u>
		<u>Per Visit</u>	<u>Duration & Utilization</u>	<u>Average Benefit</u>	<u>Duration & Utilization</u>	
Unlimited Payroll	L	L	L	S	S	L
Limited ¹ Payroll	S	S	S	L	S	S
Hours Worked	V	S	S	U	U	U
Average Wage Per Hour	U	L	V	V	S	S
Head Count (F.T.E.)	V	U	U	U	U	U

NOTES:

- V = Very likely correlated.
- L = Likely correlated.
- S = Some correlation.
- U = Unknown correlation.

Several observations can be made using the table above:

- No single exposure base is well correlated with all six of the claim cost components identified.
- "Unlimited payroll" appears to provide the best mix of claim frequency and severity correlations from among the five candidates.

1 Payroll limited to that wage generating maximum indemnity benefits.

ALTERNATIVE EXPOSURE BASES

- A medium that separately measures "hours worked" and "average wage" offers promise of better correlation with claim cost than do any of the five candidates considered on their own.

In an attempt to quantify the correlation of unlimited payroll with workers compensation costs, we asked NCCI to produce a comparison of average claim costs with pre-injury average weekly wages for contracting classes. The contracting classes were chosen based on the potential wide variation in wage levels within this employer category. The source of the information is the DCI 1980 through 1987 accident year data base for 12 states. Exhibit 8 of this report is a memorandum with charts, prepared by NCCI, that describes this data in detail. The memorandum also includes the NCCI's own conclusions regarding this material.

Graphs I through IV highlight what we believe to be the key observations to be drawn from this data. Rather than presenting the claim cost/wage comparison in absolute terms, we relied on ratios to average claim costs and average wages. This was done to recognize claim cost and wage differences across classes and regions.

Graph I shows total claim costs relative to wages. For each wage category, two bars are shown. One, designated as "actual," provides the DCI generated actual experience. The other, designated as "one-to-one," provides a purely theoretical benchmark in which total claim costs vary identically with wages. In the latter situation, unlimited payroll would provide an ideal medium for measuring average claim costs, if we assume that claim frequency is independent of average wage levels.

This graph indicates that total average claim costs do continue to increase significantly as average wages rise. However, the rate of increase in claim costs does not match that of wages.

Graphs II and III provide similar relativities by wage separately for indemnity and medical costs, respectively. As expected, indemnity and wage changes are positively correlated. However, a positive correlation between medical costs and wage increases also exists. Both graphs indicate that the proportionality of claim cost to wage increases decreases at higher wage levels.

ALTERNATIVE EXPOSURE BASES

Graph IV shows average benefit duration in weeks by wage size. Of particular significance on this graph are the relatively long benefit durations at the lowest and highest wage categories. The experience at the lowest wage category is not unexpected given the interaction of actual wages and minimal benefits. However, the experience at the highest wage category is counter intuitive in that we would expect a faster return-to-work rate for higher paid employees.

In summary, Graphs I through IV indicate to us that unlimited payroll is reasonably correlated with average claim costs for employment categories with wide wage variation potential. However, Graphs I through III, in particular, suggest that the proportionality of claim costs and wage increases tend to diminish at the higher average wage categories.

We emphasize that these observations are made without regard to the availability of the exposure medium. However, as the literature cited in Section III makes clear, issues of practicality and theory cannot be divorced when considering the merits of an exposure base. The following grid shows the predominant compensation methods and the exposure bases under consideration, and our judgmental evaluation of the availability of each base without resorting to presumptive rules:

ALTERNATIVE EXPOSURE BASES

COMPENSATION METHOD/EXPOSURE BASE MATRIX

<u>Employment Compensation Method</u>	<u>Unlimited Payroll</u>	<u>Limited² Payroll</u>	<u>Hours Worked</u>	<u>Average Wage</u>	<u>Head Count (F.T.E.)</u>
Hourly Wage	D	D	D	D	D
Salary	D	P	U	U	D
Commissions & Other Compensation Methods	P	P	U	U	D
Profit (Ownership)	U	U	U	U	D
None (Volunteer)	U	U	U	U	D

NOTES:

D = Definitely available.
P = Possibly available.
U = Unknown availability.

Three observations are drawn from the table above:

- "Head count" is the most available and verifiable exposure base. Unfortunately, it is poorly correlated with workers compensation costs.
- "Unlimited payroll" is the second most available and verifiable medium among the five compensation methods.
- A combination of "hours worked" and "average wage" is most feasible for employments actually compensated on an hourly wage basis.

2 Payroll limited to that wage generating maximum indemnity benefits.

ALTERNATIVE EXPOSURE BASES

Combining the loss correlation and feasibility observations, we first arrive at the conclusion that no single exposure base is perfect for workers compensation insurance. Secondly, "unlimited payroll" appears to provide the optimal combination of theoretical accuracy and practicality for most situations.

Third, a combination of "hours worked" and "average wage" offers promise of an improved exposure base for those employments actually compensated on an hourly basis.

Before leaving this discussion, it is important to recognize the impact of experience rating. As discussed earlier, experience rating is intended to modify premiums to better reflect individual risk characteristics. In other words, it is designed to partially correct for the theoretical deficiencies inherent in any exposure base. For workers compensation, the corrective powers of experience rating improve with the "credibility" assigned to a risk's own experience (i.e., the larger the risk, the greater the reliance on individual experience).

We can then further conclude that the loss correlation improvement to be gained through a combination of "hours worked" and "average wage" is already realized through experience rating for the larger risks (i.e., those approaching maximum credibility). The combination of "hours worked" and "average wage" is therefore most likely to improve risk assessment for the smaller employers who pay employees on an hourly basis.

In order to test these conclusions against empirical data, we refer to the NCCI data compiled for the 1985 M&R Oregon premium equity study. For comparison purposes, we are assuming that the construction employers that were the focus of the Oregon study compensate their employees strictly on an hourly basis.

The table below segregates the construction employer loss experience into high and low wage payer categories. The experience indices shown indicate relative premium redundancies (+) and deficiencies (-). Ideally, the indices for all cells would equal 0.

ALTERNATIVE EXPOSURE BASES

OREGON CONSTRUCTION EMPLOYERS (THREE YEAR LOSS EXPERIENCE)

	<u>Non-Experience³</u> <u>Rated Risks</u>		<u>Experience⁴</u> <u>Rated Risks</u>	
	<u>Distribution</u> <u>of Premium</u>	<u>Premium</u> <u>Index</u>	<u>Distribution</u> <u>of Premium</u>	<u>Premium</u> <u>Index</u>
High ⁵ Average Wage	16.6%	- 5%	35.8%	+7%
Low Average Wage	<u>83.4</u>	+1	<u>64.2</u>	- 4
Overall	100.0%	0%	100.0%	0%

For experience rated risks, this table supports the contention that "high wage" employers paid a disproportion premium by virtue of the 11 point difference in indices. For non-experience rated risks, the results were counter to the findings above, but were not as credible given the small volume of data.

A simplistic evaluation of the Oregon results would suggest that rates per \$100 of payroll should not be constant for all wage levels. This makes intuitive sense when considering the same type of work activity in the same work location. However, it is equally intuitive that wages will vary directly with employment hazard and location cost differences. In an attempt to filter out these influences from the results shown above, we did further segregate the Oregon data for union and nonunion employers. This was done under the assumption that a union/non-union analysis is more likely to reveal wage and workers compensation loss correlations in a constant work environment.

3 Reflects only one year of data and an extremely small volume of data (i.e., 2.2% of construction industry premium, or \$434,000 for 1983).

4 Reflects 1983 experience rating plan.

5 "High wage" defined as greater than \$500 per week per employee.

ALTERNATIVE EXPOSURE BASES

OREGON CONSTRUCTION EMPLOYERS EXPERIENCE RATED RISKS⁶ (THREE YEAR LOSS EXPERIENCE)

	<u>Union Employers</u>		<u>Non-Union Employers</u>		<u>Total</u>	
	<u>Premium</u>	<u>Index</u>	<u>Premium</u>	<u>Index</u>	<u>Premium</u>	<u>Index</u>
	<u>Distribution</u>		<u>Distribution</u>		<u>Distribution</u>	
High ⁷ Avg Wage	26.0%	+19%	9.8%	-26%	35.8%	+7%
Low Avg Wage	<u>27.3</u>	+ 2	<u>36.9%</u>	- 8	<u>64.2</u>	- 4
Overall	53.3%	+10%	46.7%	-12%	100.0%	0%

This additional table provides evidence that within the union employer group, wage rate recognition can improve rate equity. High wage paying union employers had a 17 point greater relative premium redundancy to the low wage payers.

The results for the non-union employer group were counter to those of the union group. The high wage payers actually had an 18 point greater relative premium deficiency than did the low wage paying group. However, it should be realized that the high wage paying non-union employers represent the smallest and, therefore, least credible experience group.

To provide further insight regarding union and non-union employer characteristics, we also calculated the average weekly wage per Oregon employee within the high and low wage categories. As the following table indicates, the union wage in each category is slightly higher:

6 Reflects 1983 experience rating plan.
7 "High wage" defined as greater than \$500 per week per employee.

ALTERNATIVE EXPOSURE BASES

OREGON CONSTRUCTION EMPLOYERS EXPERIENCE RATED RISKS

Average Weekly Wage

	<u>Union</u>	<u>Non-Union</u>	<u>Union Differential</u>
High Avg Wage	\$655	\$614	+ 7%
Low Avg Wage	379	338	+12
Overall	\$535	\$386	+39%

Of greater significance than the differences within category is the difference on an overall basis. The union employers have a much higher proportion of employees (57%) in the "high" category than do non-union employers (17%). As a result, Oregon union employees have an average wage that exceeds non-union employee wages by 39%. This suggests that the issues pertaining to union versus non-union and high versus low wage characteristics are substantially the same.

Overall, we made the following observations from this data:

- there is a wide disparity between high and low average weekly wage employers, and
- there is also a wide disparity between the results of union and non-union employers.

To the extent that these disparities can be addressed through further refinement of compensation characteristics, premium equity could be improved through wage rate recognition.

As indicated earlier, this problem was recognized and addressed by NCCI through the LRAP program. The intent of LRAP was to assign greater weight to construction employer experience modification through a judgmental 5 point "D ratio" increase. Obviously, this would only effect experience rated risks. The following table shows how the experience indices were projected to change under this plan:

ALTERNATIVE EXPOSURE BASES

OREGON CONSTRUCTION EMPLOYERS EXPERIENCE RATED RISKS⁸ (THREE YEAR LOSS EXPERIENCE)

	<u>Union</u> <u>Employers</u>		<u>Non-Union</u> <u>Employers</u>	
	<u>Pre-LRAP</u>	<u>LRAP⁹</u>	<u>Pre-LRAP</u>	<u>LRAP</u>
High ¹⁰ Average Wage	+19%	+18%	-26%	-2%
Low Average Wage	+ 2	- 8	- 8	-6
Overall	+10%	+ 5%	-12%	-5%

The projected impact of LRAP was to reduce the equity disparity in three of the four cells; the "low wage" union cell being the one exception.

At the time of the Oregon study, the Florida CCPAP was also being considered. Using the Oregon survey data, we were also able to evaluate this program's impact on rate equity in Oregon. The following table appends the CCPAP program to the previous findings:

-
- 8 Reflects 1983 experience rating plan.
 - 9 LPAP effective July 1, 1985.
 - 10 "High wage" defined as greater than \$500 per week per employee.
-

ALTERNATIVE EXPOSURE BASES

OREGON CONSTRUCTION EMPLOYERS
EXPERIENCE RATED RISKS¹¹
(THREE YEAR LOSS EXPERIENCE)

	<u>Union</u> <u>Employers</u>			<u>Non-Union</u> <u>Employers</u>		
	<u>Pre-</u> <u>LRAP</u>	<u>LRAP¹²</u>	<u>CCPAP¹³</u>	<u>Pre-</u> <u>LRAP</u>	<u>LRAP</u>	<u>CCPAP</u>
High ¹⁴ Average Wage	+19%	+18%	+11%	-26%	-2%	-34%
Low Average Wage	+ 2	- 8	+ 7	- 8	-6	- 4
Overall	+10%	+5%	+10%	-12%	-5%	-10%

The projected impact of CCPAP, if implemented independent of experience rating, was to reduce the premium disparity for two cells while plan exacerbating the disparity for two groups.

In summary, the NCCI's LRAP program appeared to be a reasonable yet indirect response to the wage differential equity problem for most classes studied: construction employers with significant union and non-union populations. In fact, the LRAP program appeared to be more effective than the more direct CCPAP approach for experience rated risks. However, the issues of rate equity for non-experience rated risks and the transportability of the Oregon findings were not resolved.

Beginning in 1989, LRAP (which affected only construction classes) was replaced by the more universal RERP. As of this date, we cannot determine how the LRAP modifications would compare with the RERP modifications for construction employers. However, it is reasonable to assume that LRAP and RERP would have the same impact on smaller insureds given that both plans are intended to increase the experience rating credibility for this population. Furthermore, it is reasonable to

11 Reflects 1983 experience rating plan.

12 LRAP effective July 1, 1985.

13 CCPAP effective January 1, 1983.

14 "High wage" defined as greater than \$500 per week per employee.

ALTERNATIVE EXPOSURE BASES

assume that RERP will result in tempered debits and credits for larger insureds, since this is a stated objective of the new plan. This could serve to unwind the rate equity introduced by LRAP for high wage paying, larger construction employers.

In retrospect, one of the key drawbacks to CCPAP when originally implemented in Florida was its independence from the experience rating modification. We believe that this is one of the primary reasons the LRAP appeared to be a superior solution to the wage differential equity problem. Effectively, CCPAP in Florida provided discounts to insureds that were inconsistent with individual risk characteristics as expressed by the experience modifiers.

To test the effect of applying a CCPAP plan with RERP, we developed rates for 20 hypothetical risks with two sets of identical theoretical costs, but with varying wage characteristics. The details of the calculation are provided in Exhibit 1. As shown below, the results of that exercise indicate that the combination of CCPAP and adjustment of RERP for CCPAP can potentially improve rate equity for the problem classes under both cost scenarios.

VARIANCE OF PREMIUM FROM THEORETICAL COST

	<u>Unlimited Payroll with RERP Cost Scenario</u>		<u>Unlimited Payroll with CCPAP and Adjusted RERP Cost Scenario</u>	
	<u>#1</u>	<u>#2</u>	<u>#1</u>	<u>#2</u>
	<u>Average Contractor</u>			
Maximum Overcharge	+27%	+22%	+13%	+4%
Maximum Undercharge	- 26	- 27	- 13	- 4
<u>Large Contractor</u>				
Maximum Overcharge	+22%	+17%	+12%	+4%
Maximum Undercharge	- 19	- 20	- 9	- 2

It is significant that the CCPAP plans recently filed in Missouri and Massachusetts recognize that CCPAP should not be independent of experience rating. The Missouri plan required an experience modifier of 1.05 or lower to qualify for CCPAP. The

ALTERNATIVE EXPOSURE BASES

Massachusetts and Pennsylvania plans adjust the experience rating expected losses for the CCPAP credit.

Included as Exhibits 2, 3, and 4, respectively, are the Florida, Missouri, and Massachusetts CCPAP plans referred to above. We have also included the recently replaced Oregon LRAP plan as Exhibit 5.

C. Conclusion

Our analysis indicates that unlimited payroll combined with RERP still results in a reasonable premium basis for most classes of insureds. However, a review of the theoretical issues, an analysis of the limited empirical data and a test of hypothetical risk situations (see Exhibit 1) indicates that equity problems attributable to wage differences may exist for certain classes of employers:

1. those involved in activity for which average hourly wages can vary greatly for the same type and locale of activity, and
2. those who do not qualify for RERP or have low credibility under the plan.

It appears that this problem is most likely isolated to those locations and employer groups that have a high concentration of both union and non-union employees. Therefore, any change in the rating system addressing this issue should be limited to those problem classes to avoid unnecessary premium instability.

One possible course of action would be to extend use of the CCPAP to other states and classes. In that case, we believe that the experience rating plan calculations for such risks should be adjusted to reflect the implementation of CCPAP. The Massachusetts plan included as Exhibit 4 provides a reasonable model from which a more permanent and transportable rating procedure could be developed. Two specific features of this plan deserve close review and reconsideration:

ALTERNATIVE EXPOSURE BASES

1. it only applies to experience rated risks, and
2. its application is not dependent on a qualification standard as to the direction and magnitude of the experience modifier.

These two features may be at odds with the equity enhancement goal of the CCPAP.

ALTERNATIVE EXPOSURE BASES

ALTERNATIVE EXPOSURE BASES

V. EVALUATION OF WAGE(S) RATE EXPENSES (OBJECTIVE 6b)

The objective of this aspect of the examination was to evaluate what additional expenses would be involved in recognizing wage(s) rates as a supplement to the unlimited payroll exposure base. The additional expenses considered are those immediately absorbed by insureds, insurers, and NCCI. Ultimately, all additional costs would be passed on to the insureds through the premium paid.

This part of the review of alternative exposure bases represents the joint efforts of M&R and Arthur Andersen & Co., a subcontractor to M&R in the examination.

A. Data Sources

Data specific to this assignment are not readily available. Therefore, we relied heavily on special cost data compiled by NCCI and on information compiled from a telephone survey of insurers of various sizes and operational characteristics. Furthermore, we were provided copies of historical correspondence on the topic by NCCI. These included memoranda concerning Texas (1982), Oregon (1979), Washington (1979 and 1988), and New York (1989).

B. Analysis of Cost

In order to recognize wage rate(s) within the rating structure, one new statistical element would have to be captured for each insured: number of hours worked. Our investigation suggests that it would be difficult and/or expensive to compile this information for all insureds.

At this time, hours worked are used in rating all risks in only one state: Washington. This state, where workers compensation coverage is provided by an exclusive state fund, converted from a payroll exposure base to an hours worked base in the 1930's to offset the payroll deflation of the depression. Subsequent attempts to change back to a payroll base have been unsuccessful largely due to resulting premium disruptions.

ALTERNATIVE EXPOSURE BASES

Hours worked are used in rating construction employers in the six CCPAP states: Delaware, Florida, Missouri, Massachusetts, Oregon, and Pennsylvania. Furthermore, they are used in California and Nevada to administer two-tiered classification structures for construction employments. However, in all eight cases the onus is on the employer to compile verifiable hours worked data. Failure to do so results in use of the highest applicable manual rate. In none of the states are hours worked captured as a separate element of the statistical plan, nor are they explicitly used in the ratemaking process.

We have identified seven areas of potential additional cost due to capturing and explicitly using hours worked in the rating and ratemaking processes:

1. insured record-keeping to the extent that hours worked are collected for employees not compensated on an hourly basis,
2. insurer collection of this additional data,
3. insurer and NCCI verification of hours worked,
4. insurer reporting of hours worked to NCCI,
5. NCCI acceptance of the expanded insurer reports,
6. NCCI usage of hours worked for ratemaking, and
7. NCCI usage of hours worked for experience rating.

In order to evaluate the potential cost impact of the first four items listed above, Arthur Andersen and M&R surveyed several insurers for their insights. We supplemented the insurer responses with a review of past discussions on this topic among NCCI, the American Insurance Association, and various states.

We generally received pessimistic responses with regard to the essential feasibility and potential cost of compiling hours worked. This was not surprising since the insurers were being asked to opine on a process that would inevitably complicate the administration of workers compensation insurance no matter how it is done.

ALTERNATIVE EXPOSURE BASES

Furthermore, the survey was not able to elicit any detailed analysis of potential costs. Again, this is not surprising since the insurers have no benchmark from which to measure the impact of collecting hours worked.

Despite these drawbacks, the survey identified a consensus on the following issues:

1. Most insurers believed that insureds who actually pay employees on a hourly basis, specifically subsets of the contracting and manufacturing industries, have verifiable records readily available.
2. Any attempt to have insureds begin to collect hours worked just for workers compensation purposes would be problematical.
3. Even limiting the process to insureds with verifiable records of hours worked will significantly complicate the audit function. This is due to the lack of uniformity among employers in hours worked record-keeping.
4. The estimated cost impact of collecting and verifying hours worked ranged from a "nominal increase" to "at least doubling."
5. The collection of additional exposure data would affect existing underwriting procedures and systems. This would increase the expense of underwriting a policy and could introduce delays in binding coverage.

In an effort to translate the survey findings into a reasonable cost estimate, we researched historical expense information to establish a framework to project expenses. At this time, approximately 6% of the nationwide premium dollar is earmarked for general expense (i.e., basic policy maintenance costs). However, we are not aware of any data source that definitively segregates the general expenses into various functions (e.g., payroll audit).

Going to a different data source (data compiled by the California Department of Insurance), we find that payroll audit expenses range between 0.6%, and 1% of the premium dollar. Noting that the organizations represented in this data compilation place a higher emphasis on the audit function than many other types of insurers in

ALTERNATIVE EXPOSURE BASES

other jurisdictions, it is reasonable to assume that a more representative estimate of payroll audit expense is at the lower end of the range (0.6%).

One study, produced by the New York Compensation Insurance Rating Board (Exhibit 6), suggests that audit expenses will increase by 26% for the effected classes. It is important to note that this study was limited to contractor employers, a group for which hourly records are probably more complete than for the average employer.

Another study completed in the state of Washington (in 1989), indicates that an average audit in the "hours worked" state takes 13.9 hours to complete. This is approximately ten hours (or 250%) more than the four hours estimated by NCCI for a payroll based audit. It is important to realize that the Washington audits do encompass classes for which hourly records may not be kept for non-insurance reasons. Also, it is not clear that the additional time translates into additional costs on a proportional basis.

These two sources indicate that audit costs will increase in the range of 26% to 250% due to hours worked, with the lower end of the range having a higher probability. Therefore, it is reasonable to expect the 0.6% audit cost provision to increase by 0.2 to 0.4 points due to introduction of hours worked for affected classes.

Use of hours worked will also increase the internal administrative costs of insureds who do not normally compensate employees on an hourly basis. We are not able to estimate the level of these costs; however, they may be significant for insureds who would be required to implement a new record-keeping system for this purpose.

Through Arthur Andersen, NCCI has provided estimates (Exhibit 7) of the additional costs that reporting and using hours worked would entail if this exposure element were fully integrated into the rating system. The Council has provided the estimates under two scenarios:

1. hours worked are integrated on a stand alone basis, and
2. hours worked are integrated as part of a more extensive rewrite of the statistical plan and policy information system currently under review.

ALTERNATIVE EXPOSURE BASES

The following table summarizes the NCCI cost estimates:

HOURS WORKED IMPLEMENTATION COSTS

<u>Function</u>	<u>Initial Costs</u>		<u>Ongoing Costs</u>
	<u>Stand Alone</u>	<u>Part of Rewrite</u>	
Reporting	\$150,000	\$ 0	\$20,000
Ratemaking	375,000	75,000	0
Experience Rating	<u>450,000</u>	<u>75,000</u>	<u>0</u>
Total	\$975,000	\$150,000	\$20,000

Although implementation costs in the \$150,000 to \$975,000 range are not insignificant, the expense as a percentage of nationwide premium is negligible. However, there would be indirect costs that defy estimation. For example, NCCI indicated that the magnitude of this project could impede their ability to proceed with other system development efforts at the same time. The inherent delays could have some cost impact. As the discussion above illustrates, it is extremely difficult, if not impossible, to derive an accurate total cost estimate for capturing and using hours worked. To a large extent, this is dependent on exactly how the new exposure base is integrated into the rating system. However, we do believe that sufficient information does exist to permit a rough estimate as summarized below:

HOURS WORKED IMPLEMENTATION COSTS ESTIMATED AS A PERCENTAGE OF PREMIUM

Insurer/NCCI Audits	0.2% to 0.4%
Insured/Agent Record-Keeping ¹⁵	0.1% to 0.2%
NCCI Costs ¹⁶	<u>0.1% to 0.1%</u>
Total	0.4% to 0.7%

15 Estimated as 50% of the insurer/NCCI audit costs.

16 Reflects the Arthur Andersen findings and the uncertainty inherent in the estimates contained therein.

ALTERNATIVE EXPOSURE BASES

In total, this data implies that universal introduction of hours worked into workers compensation rating for all insureds would add approximately 0.4% to 0.7% to the total system costs. Of course, this analysis is premised on the assumption that hours worked data is available. As discussed below, this assumption cannot be verified for all categories of insureds.

C. Analysis of Feasibility

As indicated above, the cost of compiling hours worked for purposes of a workers compensation premium base may be manageable. However, the ability to compile hours worked at a reasonable cost does not guarantee that the resulting data is suitable for determining premiums, even if there is a strong theoretical argument in favor of its use. Our foundation for this statement is Dorweiler's comment on practicality and the following quote from Insurance Company Operations, Volume II, Webb et al.:

"Second, it [a good exposure base] should be easy for the insurer to determine. Finally, it should be difficult for the insured to manipulate."

The following paragraphs provide a review of the practical problems inherent in hours worked compilation that are not directly related to the costs of the process. This discussion is included under the expense evaluation heading because these problems do result in indirect expenses that may be borne by the insurers and ultimately will be borne by some segment of the insured population.

Based on our review of historical information supplemented with our survey results, the key drawback to use of hours worked is that not all employers currently collect this data. There does not appear to be a universal requirement to collect this data, for reasons unrelated to workers compensation insurance. Even in those jurisdictions where this information is compiled (e.g., Washington), there is reliance on presumptive rules for approximating hours worked in those situations where compensation is not directly related to time worked.

ALTERNATIVE EXPOSURE BASES

Conceivably, use of the same presumptive rules could be extended to workers compensation as well. However, this would introduce an arbitrary aspect to workers compensation rating that does not exist under the payroll based system.

This action would neither enhance quantification of inherent hazard nor improve the accuracy of the exposure medium. Therefore, introduction of hours worked would have minimal, if any, benefit from an equity standpoint for most classes of employment that are not predominantly populated by employees compensated on an hourly basis.

Assuming that hours worked was used as a supplemental exposure medium for only the employers who compensate employees on an hourly basis, the task of identifying such employer groups remains. The data compiled for this study suggests that this is not a simple undertaking. For example, a study (Exhibit 6) of New York construction employers, conducted by the New York Compensation Insurance Rating Board, indicated that only 53% of the employers audited had some form of hourly records. Furthermore, none of the employers who maintained hourly records maintained them by category of work activity that would approximate the current workers compensation classification system.

Thus, even with a group of employers (e.g., contractors) that are predominantly in an hourly wage industry, the type of records needed to use hours worked as an exposure base apparently are not now maintained in a format consistent with payroll. This situation leads to the following choices:

1. create and impose a new record-keeping requirement just for workers compensation, or
2. allow those who do maintain hours worked to access a special rating plan for workers compensation.

The first approach would be a violation of the "already used...for other than insurance purposes" tenet. The second approach would create an opportunity for adverse selection that could jeopardize the financial soundness of the rating plan.

ALTERNATIVE EXPOSURE BASES

We anticipate that the availability and comparability of hours worked records will vary greatly by jurisdiction and by employer group. However, it is not clear, based on the current state of records maintained, that hours worked are as readily verifiable as payroll data. Successful introduction of hours worked as a supplemental exposure base may require a re-orientation of record-keeping among insureds that is not just a matter of cost.

ALTERNATIVE EXPOSURE BASES

VI. RECOMMENDATIONS

As indicated in prior sections of this report, we do believe that wage recognition can improve rate equity for certain groups of insureds. Furthermore, the cost of compiling and using hours worked as an exposure base supplement for employers who pay the employees on this basis appears to be manageable. However, universal implementation of an hours worked or wage differentiation plan would be counterproductive from an equity standpoint.

In response to these findings, we recommend continued judicious use of wage recognition plans only for those states and those classes of employment identified as having residual inequities after application of RERP to the unlimited payroll exposure base. Even for those classes, equity will not be served by substituting hours worked for unlimited payroll. Rather, we suggest a plan that combines wage rates with unlimited payroll.

At this time, we are aware of two categories of wage differentiation plans in use. The first category, which is referred to as the California plan, segregates the construction class employees into two tiers based on an hourly wage threshold. A higher rate per \$100 of unlimited payroll is applicable to employees classified below the threshold. The second category of plans (i.e., the CCPAP plans), provide discounts for average hourly payrolls above a specified level. The result is a multi-tiered discount schedule ranging from 0% to 20% or 25%.

In our opinion, the CCPAP approach is preferable. This plan, which provides for a graduated scale of discounts based on wage differentials, would appear to enhance rate equity more than a two-tiered system. Additionally, the incentive to manipulate data at or near the two-tier wage boundary would be diminished.

There are variations in the treatment of experience rating modifiers among the CCPAP plans in use. Under the original Florida plan, the CCPAP discount and experience rating modifier are independent and unrelated rating steps. Under the Missouri and Oregon plans, insureds qualify for CCPAP only if their experience modification is no greater than 1.05 and 1.00, respectively. Under the Massachusetts plan, only experience rated risks are eligible and the expected losses for the experience rating calculation are adjusted for the applicable CCPAP discount.

ALTERNATIVE EXPOSURE BASES

Particularly with the introduction of RERP, we believe that independent application of CCPAP and experience rating modifications will over-compensate for inequities caused by wage differentials. The Missouri and Oregon plans partially address this issue through qualifications standards based on the magnitude of the experience rating factor. The Massachusetts plan (see Exhibit 4) more formally integrates the CCPAP credits with experience rating and, in our opinion, is the best available prototype for future use. However, even this plan has certain features (e.g., application only to experience rate risks without an experience modifier qualification criterion) that deserve further review.

A key characteristic of all CCPAP plans is that the insured is responsible for collecting the hours worked and average hourly wage data in a readily verifiable format. Given that the plans offer only discounts, there is no disincentive to compile the necessary wage data. With the uncertainty surrounding the availability of hours worked for all employers within a targeted class, we believe that these are absolutely essential features of CCPAP.

Two potentially negative attributes concerning CCPAP should be considered. First, those insureds who do not qualify for wage discounts will pay more as the class base rates are increased to offset applicable credits. This is not necessarily unfair, given the results of the Oregon study for low average wage paying employers. Second, those insureds who would qualify for discounts but have not compiled the necessary wage records will also pay more. To avoid such an increase in workers compensation premiums, these insureds will have to assume a new record-keeping burden and the attendant costs.

The average hourly wage thresholds and the corresponding discounts under CCPAP have historically been a matter of judgment. Given the lack of empirical data, this is understandable. However, if CCPAP is to be expanded to other jurisdictions or classes, it would be advisable to establish more formal guidelines for developing wage rate discount schedules. The following are our recommendations:

1. Only those classes that have a verifiably wide range of wages for the same type and locale of work activity should be subject to the schedules. Wage differentials attributable to variances in economic conditions by region or job safety characteristics

ALTERNATIVE EXPOSURE BASES

would not be a motivating factor for a discount plan. Due to variations by jurisdiction, we are reluctant to define a "verifiably wide range." However, we understand that this situation is likely to occur when two or more distinct wage scales are applicable. This would appear to be common for classes with a significant population of both union and non-union employees.

2. Discounts should only be applicable for insureds with an average hourly wage that exceeds the average hourly wage for all the subject CCPAP plan classes combined. This approach specifically limits application of discounts to classes with "higher than average" wages; i.e., those most likely to experience a residual inequity.
3. The maximum discount should only be applicable at an average wage generating at least the maximum indemnity benefits in the jurisdiction.
4. The actual scaling of the discounts by average wage category would be dependent on two factors. The first is the actual benefit structure in the jurisdiction. The second is the actual dispersion of wages for the subject classes.
5. A formal survey procedure for determining average wages and the variances about the average should be instituted. This will facilitate development of reasonable discounts and estimation of resulting offsets.
6. The survey should be updated annually or bi-annually until such time as empirical data is compiled.

A major drawback to the CCPAP plans is that there does not presently exist a mechanism to test the appropriateness of the discounts. NCCI has developed a procedure to monitor the offsets by class that the discount schedule creates. However, no procedure for regularly comparing the loss experience of insureds falling into the various discount categories has been established. As a result, no empirical data on which to base adjustments to the CCPAP discount schedule is readily or routinely captured.

One of the primary reasons for not capturing premium and loss data by CCPAP discount category is that this information is not included in the Workers Compensation Statistical Plan (WCSP). This is understandable since the CCPAP plans

ALTERNATIVE EXPOSURE BASES

were not considered permanent by NCCI and, therefore, did not warrant a change in the WCSP structure. However, we recommend that the WCSP be modified to capture the CCPAP discount class data if this rating approach is extended to other jurisdictions. At this time, the CCPAP plan appears to warrant a more permanent position in NCCI's ratemaking efforts.

From an analytical standpoint, the ideal modification to the WCSP would be to actually record the average hourly wage by class. However, this approach would substantially complicate the WCSP coding process and would consume valuable unit report space. A practical alternative would be to assign a one or two digit sub-class code for insureds participating in the CCPAP based on the magnitude of the discount by class.

One problem with the CCPAP's as they now exist, is that the average hourly wage thresholds are static. There is not an automatic mechanism for adjusting the thresholds for changes in wage levels that occur as the result of general inflation or collective bargaining agreements. If no adjustments are made, the number of insureds receiving discounts will increase without justification. Ultimately, the original value of wage rate differentiation will be diminished. Therefore, we recommend that the wage thresholds inherent in the CCPAP plans be indexed to average statewide wage changes or a similar indicator. At a minimum, the wage thresholds should be subject to regular review on an annual or bi-annual basis.

As a final recommendation, we do suggest that the NAIC consider additional research regarding the CCPAP plans. The objectives of this research would be two-fold:

- to update the 1984-1985 Oregon empirical data with a compilation and review of actual premium and loss experience under the Florida CCPAP plan, and
- to further evaluate the attributes of the Massachusetts CCPAP for incorporation into a universal prototype plan.

ASSUMPTIONS

1a. SCENARIO #1 - Cost/Benefit Structures:

- a. 40% of cost for medical benefits.
- b. 10% of cost for low maximum compensation (e.g., "permanent partial" benefits).
- c. 50% of cost for high maximum compensation (e.g., "temporary total" benefits).
- d. \$600 weekly wages qualifies for maximum compensation.
- e. Frequency related to hours worked.
- f. Medical costs increase 20% for doubling of weekly wages.
- g. Indemnity severity varies due to weekly wages.

1b. SCENARIO #2 - Cost/Benefit Structures:

- a. 40% of cost for medical benefits.
- b. 50% of cost for low maximum compensation (e.g., "permanent partial" benefits).
- c. 10% of cost for high maximum compensation (e.g., "temporary total" benefits).
- d. \$600 weekly wages qualifies for maximum compensation.
- e. Frequency related to hours worked.
- f. Medical costs increase 20% for doubling of weekly wages.
- g. Indemnity severity varies due to weekly wages.

2. Average worker works 35 hours per week, 45 weeks per year, at \$16 per hour.

3. RERP structure:

- a. Average claim size \$2750.
- b. D-ratio 30%.
- c. Expected loss rate 50% of prospective cost.
- d. Average loss experience; for average contractor (only) severity proportional to average weekly wage.
- e. Adjusted overall collected premium for the ten given employers (includes offset to manual rates for RERP and CCPAP).

CALCULATIONS FOR EMPLOYER NUMBER 1

SCENARIO #1

	<u>RERP</u>	<u>CCPAP</u>
1. Weekly Wages per Employee	\$ 560	\$ 560
2. Annual Wages per Employee	25,200	25,200
3. Payroll for Eight Employees	201,600	201,600
4. Manual Rate	9.64	12.21
5. Hourly Wage Credit		19.7%
6. Manual Premium	19,434	19,766
7. Expected Losses	29,144	29,651
8. Actual Primary Losses	9,000	9,000
9. Actual Excess Losses	21,000	21,000
10. B	9,363	9,421
11. W	0.091	0.092
12. Mod Factor	1.008	1.003
14. Actual Premium	\$ 19,587	\$ 19,832

NOTES:

1. Actual calculations used more significant digits than shown above.
2. Above rounding conventions may not be followed in any given state.

NOTES FOR EXHIBIT 3a
CALCULATIONS FOR EMPLOYER NUMBER 1

SCENARIO #1

The hourly wage, the number of hours worked per week, and the number of weeks worked per year vary according to the description shown on page 4 of Exhibit 1. The theoretical cost is based on the assumptions given on page 2. These assumptions include the percentage of costs that are attributable to medical benefits (40%), low maximum compensation (10%), and high maximum compensation (50%). In addition, medical benefits are assumed to increase 20% for a doubling of wages; and wages of \$600 per week qualifies for the maximum benefit. These costs are shown on page 5. The cost factors have been reduced to a cost per hour worked, which is a function of the weekly wage. Obviously, this cost function is hypothetical and it makes various assumptions that might not be subject to measurement in practice.

For each sample employer, the weekly wage and cost per hour worked are shown on page 4. The example has been constructed so that each employer has the same theoretical cost (\$20,000 or \$200,000) for the year. The total number of hours worked for the employer for the year is determined by dividing the annual theoretical cost by the cost per hour worked.

The manual rates have been balanced to the total cost for the sample group of employers. This follows the normal ratemaking procedure of balancing premiums and costs for the given insured population. The hourly wage credits are based on the theoretical cost function, converting the weekly wage to an hourly wage by dividing by 35.

The manual premium for an employer is determined by multiplying the total payroll by the manual rate (and subtracting the hourly wage credit, for the CCPAP calculation). The expected losses are 150% of the manual premium (subject to rounding). This results from using three years of experience and assuming that expected losses for one year will be 50% of premium for that year. The actual primary and excess losses are assumed to be the same for all employers; the total for all employers equals 150% of the theoretical cost. The B, W, and mod factor calculations all correspond to the current RERP formula, with an average claim size of \$2,750 (subject to rounding differences). The actual premium is the manual premium times the mod factor.

FLORIDA CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM

The premium adjustment program originally approved effective January 1, 1984, for employers having exposure in any of the contracting classifications in Florida, has been extended into 1991. This program is mandatory and is applicable to all policies having anniversary rating dates during 1991 covering one or more of the eligible contracting classifications.

The Florida Contracting Classification Premium Adjustment Program is designed to vary an employer's workers compensation premium by way of a premium credit based upon the employer's average wage level. While the initial determination of any applicable credit is computed on a class by class basis, the credit (if any) will be applied to the employer's entire Florida standard premium in order to facilitate the carrier's application of the credit.

The premium adjustment program does not provide for any premium debits. Therefore, rate changes were necessitated for all the applicable classifications in order to offset the premium credits.

The premium adjustment program (See Florida Basic Manual—Special Rule, Exhibit 1) shall be administered as follows:

1. Each carrier shall issue a letter having standardized text (Exhibit 2) to any insured having a policy containing one or more of the applicable classifications. One letter must be issued for each qualifying policy. This letter (which must be printed by each individual carrier) should be sent to the insured prior to policy issuance or within sixty days after effective date. The carrier must maintain proof of mailing in its files and make such proof available to the Florida Insurance Department on request.
2. The insured shall complete the required information and mail the completed form to NCCI's Atlantic Division, formerly South Atlantic Council on Compensation Insurance.
3. NCCI's Atlantic Division will compute the insured's average hourly wage for each classification, the applicable classification premium credit, and the overall policy credit factor. These calculations will be displayed on a Policy Credit Work Sheet (Exhibit 3). A copy of this work sheet will then be mailed to the carrier.
4. The carrier shall use this policy credit factor in the calculation of the insured's estimated premium at policy issuance. In those cases where the carrier receives the policy credit factor after the insured's policy has been issued, the policy shall be so endorsed (See Exhibit 4).
5. Upon audit, the carrier shall use the same policy credit factor in the calculation of the insured's final earned premium. Additionally, the carrier shall verify the data originally provided by the insured for the computation of the policy credit factor by reviewing those records upon which the insured's data was originally based. If this process uncovers any errors, revised payroll and/or hours worked, data must be submitted to NCCI's Atlantic Division. The revised data will be used to calculate a revised policy credit factor.

Contact: James R. Nau, Director 407-997-4563

6. The policy credit factor is to be applied to the premium determination process directly after the application of experience modification and prior to any deviations and premium discount. The policy credit factor, if available upon policy issuance, must be displayed on the policy Declarations Page. If the factor is not available upon policy issuance, the required endorsement must be attached to the policy.
7. The earned premium dollar adjustment amount due to the application of the policy credit factor must be reported on unit statistical reports under Classification Code 9046. This amount must be reported on lines D, E, F or G since it is not subject to experience modification (See Exhibit 5).
8. No adjustment to aggregate standard earned premium reported on the aggregate Calls for Experience is required because of this premium credit. In other words, reported aggregate standard earned premium must include the effects of these premium credits.

Please review the above, along with the attached exhibits, carefully with your underwriting, auditing and statistical personnel.

Attachments

**FLORIDA BASIC MANUAL—SPECIAL RULE
FLORIDA CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM**

The Florida Contracting Classification Premium Adjustment Program provides for a premium credit for up to one year for a policy which contains one or more contracting classifications. A credit may be applicable to those policies commencing with their anniversary date in calendar year 1991.

The basis for determining the credit is the total payroll (excluding overtime premium pay) and hours worked for each contracting classification for the third calendar quarter in 1990 as reported to taxing authorities. If the insured did not engage in operations for the complete quarter, then the last complete quarter prior to policy year inception shall be used or, if there was no complete quarter of operations prior to the policy inception, then the first complete quarter after policy inception shall be used. A credit may be determined for each contracting classification by dividing the total payroll, excluding overtime premium pay, by the number of hours worked to arrive at the average hourly wage for the classification. In the absence of specific records for salaried employees, it will be assumed each such individual worked forty (40) hours per week. The credit for average hourly wage is listed below:

<u>Average Hourly Wage</u>	<u>Credit From Manual Prem.</u>	<u>Average Hourly Wage</u>	<u>Credit From Manual Prem.</u>
\$ 9.99 or less	None	\$13.76–\$14.00	15%
\$10.00–\$11.50	5%	\$14.01–\$14.25	16%
\$11.51–\$11.75	6%	\$14.26–\$14.50	17%
\$11.76–\$12.00	7%	\$14.51–\$14.75	18%
\$12.01–\$12.25	8%	\$14.76–\$15.00	19%
\$12.26–\$12.50	9%	\$15.01–\$15.50	20%
\$12.51–\$12.75	10%	\$15.51–\$16.00	21%
\$12.76–\$13.00	11%	\$16.01–\$16.50	22%
\$13.01–\$13.25	12%	\$16.51–\$17.00	23%
\$13.26–\$13.50	13%	\$17.01–\$17.50	24%
\$13.51–\$13.75	14%	over \$17.50	25%

The total contracting classification credit amount, in dollars, must be calculated and then divided by the total policy premium at manual rates—including contracting and non-contracting classifications. The result would be the percentage credit which is to be applied to the 1991 policy. When calculating the total policy credit the percentage shall be rounded to the nearest whole number with .5 being rounded upward (as an example, 4.4 rounded to 4% and 4.5 rounded to 5%).

The insured shall submit the required payroll and hours worked information to the National Council on Compensation Insurance, Atlantic Division, for calculation of any applicable credit. The carrier shall, upon audit, verify the information that was submitted by the insured and used in the calculation of the credit. If the carrier discovers an error in the original request for policy credit, the revised information must be submitted to the National Council on Compensation Insurance, Atlantic Division, for recalculation. If the insured does not furnish records to verify the payrolls and hours worked originally submitted and used in the calculation of the credit, there shall be no credit applied to the policy.

The credit, authorized by the National Council on Compensation Insurance, Atlantic Division, shall appear on item 4 of the Policy. If the credit is not available at the time of policy issuance, the carrier shall endorse the policy to provide this credit information.

Carriers are required to use the approved form to notify all their insureds, who have one or more contracting classifications on their policy, that they may be eligible for a premium adjustment credit.

“Contracting classifications” are those classifications subject to the following code numbers:

0050	5040	5213	5445	5538	6018	6235	7601
0052	5057	5215	5462	5551	6045	6236	7855

**FLORIDA CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM
WORKERS COMPENSATION PREMIUM CREDIT APPLICATION FOR 1991**

The Florida contracting classification Premium Adjustment program has been extended for employers engaged in contracting operations and is applicable to policies *with effective dates on or after January 1, 1991*.

A special premium calculation, which may result in a premium credit for you, will be based on average hourly pay rates for each classification of contracting operations. In order that your premium may be correctly established, please return the completed premium credit application, as set out on the reverse side of this letter, to the

National Council on Compensation Insurance
Atlantic Division
P.O. Box 3098
Boca Raton, FL 33431

They will advise us of any premium credit applicable.

If they do not receive this application, your 1990 premium calculation will not reflect any possible premium credit.

For each applicable classification (both contracting and non-contracting) covering your company's operations in the state of Florida, report the *total* Florida payroll (excluding overtime premium pay) and the corresponding *total* number of hours worked, *for the third calendar quarter (JULY, AUGUST, SEPTEMBER) of 1990 as reported to taxing authorities*.

Note #1: If you did not engage in contracting operations during the third quarter of 1990, the requested information to be provided should, then, be for the last complete calendar quarter prior to the effective date of your workers compensation policy.

Note #2: If you are a *new business (no prior operations)*, submit the requested information, *for the first complete calendar quarter following the effective date of your workers compensation policy when available*.

Note #3: In the absence of specific records for salaried employees, you should assume that each individual worked forty (40) hours per week.

Please preserve your payroll records which formed the basis for this declaration as we will be required to verify the reported information in order for any premium credit to be applied.

Thank you for your cooperation.

Sincerely,

Turn Page Over For Premium Credit Application

FLORIDA CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT ENDORSEMENT

The premium for the policy may be adjusted by a Florida Contracting Classification Premium Adjustment factor. The factor was not available when the policy was issued. If you qualify, we will issue an endorsement to show the premium adjustment factor after it is calculated.

Notes:

1. This endorsement may be used when an insured's credit adjustment factor is not available when the policy is issued.
2. An appropriate typewritten entry may be made on the policy Information Page, Item 4, instead of using this endorsement.

STATISTICAL REPORTING

1. The earned premium dollar adjustment amount due to the application of the policy credit factor must be reported on unit statistical reports under Classification Code 9046. This amount must be reported on lines D, E, F or G since it is not subject to experience modification.
2. No adjustment to aggregate standard premium reported on the aggregate Call for Experience is required because of this premium credit. In other words, reported aggregate standard earned premium must include the effects of these premium credits.

MISSOURI CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM

The Missouri Division of Insurance has approved the Missouri Contracting Classification Premium Adjustment Program effective January 1, 1990. The program will provide a premium credit to those eligible contracting employers paying wages in excess of \$12.00 per hour per contracting employee. Employers with an experience modification of 1.06 or higher are not eligible for this program. The initial calculation of any applicable credit is computed by classification. From these, a single credit will be developed to apply to the entire standard premium for Missouri.

This program does not provide for any offsetting debits. Consequently, a rate change for contracting classifications is necessary to offset the premium credits.

The premium adjustment program is detailed in the Missouri Basic Manual—Special Rule, included as Exhibit 1. It will be administered as follows:

1. Each carrier shall issue a letter having standardized text (Exhibit 2) to any insured having a policy containing one or more of the applicable classifications. One letter must be issued for each qualifying policy. This letter (which must be printed by each individual carrier) should be sent to the insured prior to policy issuance or within sixty days after effective date. The carrier must maintain proof of mailing in its files and make such proof available to the Missouri Division of Insurance on request.
2. The insured should complete the requested information and mail the completed form to NCCI's Midwestern Division.
3. NCCI's Midwestern Division will compute the insured's average hourly wage for each classification, the applicable classification premium credit, and the overall policy credit factor. These calculations will be displayed on a Policy Credit Work Sheet (Exhibit 3). A copy of this work sheet will then be mailed to the carrier.
4. The carrier shall use this policy credit factor in the calculation of the insured's estimated premium at policy issuance. In those cases where the carrier receives the policy credit factor after the insured's policy has been issued, the policy shall be so endorsed (as required in Exhibit 4).
5. Upon audit, the carrier shall use the same policy credit premium in the calculation of the insured's final earned premium. Additionally, the carrier shall verify the data originally provided by the insured for the computation of the policy credit factor by reviewing those records upon which the insured's data was originally based. If this process uncovers any errors, revised payroll and/or hours worked data must be submitted to NCCI's Midwestern Division. The revised data will be used to calculate a revised policy credit factor.
6. The policy credit factor is to be applied to the premium determination process directly after the application of experience modification and prior to any deviations and premium discount. This policy credit factor, if available upon policy issuance, must be displayed on the policy Declarations Page. If the factor is not available upon policy issuance, the required endorsement must be attached to the policy (see Exhibit 4).

Contact: Kenneth Robinson, Director 314-843-4001

7. The earned premium dollar adjustment amount due to the application of the policy credit factor must be reported on unit statistical reports under Classification Code 9046. This amount must be reported on lines D, E, F or G since it is not subject to experience modification (see Exhibit 5).
8. No adjustment to aggregate standard earned premium reported on the aggregate Calls for Experience is required because of this premium credit. In other words, reported aggregate standard earned premium must include the effects of these premium credits.

Please review the above, along with the attached exhibits, carefully with your underwriting, auditing and statistical personnel.

MISSOURI BASIC MANUAL - SPECIAL RULE
MISSOURI CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM

Exhibit 1

The Missouri Contracting Classification Premium Adjustment Program provides for a premium credit for up to one year for a qualifying policy. To qualify, a policy must contain one or more contracting classifications and have an experience rating of 1.05 or lower. Policies not subject to experience rating will be eligible for the Missouri Contracting Classification Premium Adjustment Program. The Missouri Contracting Classification Premium Adjustment Program may be applied to qualifying policies with an anniversary rating date of January 1, 1990 and thereafter.

The basis for determining the credit is the total payroll (excluding overtime premium pay) and hours worked for each contracting classification for the third calendar quarter of the year preceding the policy anniversary rating date as reported to taxing authorities. If the insured did not engage in operations for the complete quarter, then the last complete quarter prior to the policy year inception shall be used, or, if there was no complete quarter of operations prior to the policy inception, then the first complete quarter after the policy inception shall be used. A credit may be determined for each contracting classification by dividing the total payroll, excluding overtime premium pay, by the number of hours worked to arrive at the average hourly wage for the classification. In the absence of specific records for salaried employees, it will be assumed each such individual worked forty (40) hours per week. The credit for average hourly wage is listed below:

<u>Average Hourly Wage</u>	<u>Credit from Manual Premium</u>
\$11.99 or less	None
\$12.00 - \$13.50	5%
\$13.51 - \$14.00	6%
\$14.01 - \$14.50	7%
\$14.51 - \$15.00	8%
\$15.01 - \$15.50	9%
\$15.51 - \$16.00	10%
\$16.01 - \$16.50	11%
\$16.51 - \$17.00	12%
\$17.01 - \$17.50	13%
\$17.51 - \$18.00	14%
\$18.01 - \$18.50	15%
\$18.51 - \$19.00	16%
\$19.01 - \$20.00	17%
\$20.01 - \$20.50	18%
\$20.51 - \$21.00	19%
\$21.01 and over	20%

The total contracting classification credit amount, in dollars, must be calculated and then divided by the total policy premium at manual rates - including contracting and noncontracting classifications. The result would be the percentage credit which is to be applied to the qualifying policy. When calculating the total policy credit, the percentage shall be rounded to the nearest whole number with .5 being rounded upward. (As an example, 4.4 rounded to 4% and 4.5 rounded to 5%.)

The insured shall submit the required payroll and hours worked information to the NCCI - Midwestern Division for calculation of any applicable credit. The carrier shall, upon audit, verify the information that was submitted by the insured and used in the calculation of the credit. If the carrier discovers an error in the original request for policy credit, the revised information must be submitted to the NCCI - Midwestern Division for recalculation. If the insured does not furnish records to verify the payrolls and hours worked originally submitted and used in the calculation of the credit, there shall be no credit applied to the policy.

The credit, authorized by the NCCI - Midwestern Division, shall appear on Item 4 of the Policy. If the credit is not available at the time of policy issuance, the carrier shall endorse the policy to provide this credit information.

Carriers are required to use the approved form to notify all of their insureds, who have one or more contracting classifications on their policy, that they may be eligible for a premium adjustment credit.

"Contracting classifications" are those classifications subject to the following code numbers:

0050	5040	5188	5403	5505	5703	6216	6306	9534
1322	5057	5190	5437	5506	5705	6217	6319	9545
3365	5059	5213	5443	5515	6003	6229	6325	9549
3719	5067	5215	5445	5538	6005	6233	6400	
3724	5069	5221	5462	5551	6045	6235	7380*	
3726	5102	5222	5474	5606	6204	6236	7538	
5020	5146	5223	5479	5610	6206	6237	7601	
5022	5160	5348	5480	5645	6213	6251	7855	
5037	5183	5402	5491	5651	6214	6252	8227	

*Code 7380 may be used only on policies where more than 50% of the total premium is produced by one or more of the contracting classifications listed.

**MISSOURI CONTRACTING CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM
WORKERS COMPENSATION PREMIUM CREDIT APPLICATION FOR 1990**

The Missouri Contracting Classification Premium Adjustment Program has been approved for employers engaged in contracting operations and is applicable to policies with effective dates on or after January 1, 1990.

A special premium calculation, which may result in a premium credit for you, will be based on average hourly pay rates for each classification of contracting operations. In order that your premium may be correctly established, please return the completed premium credit application, as set out on the reverse side of this letter, to the:

NCCI - Midwestern Division
P.O. Box 19430
Springfield, Illinois 62794-9430

They will advise us of any premium credit applicable.

If they do not receive this application, your 1990 premium calculation will not reflect any possible premium credit.

For each applicable classification (both contracting and non-contracting) covering your company's operations in the state of Missouri, report the total Missouri payroll (excluding overtime premium pay) and the corresponding total number of hours worked, for the third calendar quarter (JULY, AUGUST, SEPTEMBER) of 1989 as reported to taxing authorities.

Note #1: If you did not engage in contracting operations during the third quarter of 1989, the requested information to be provided should, then, be for the last complete calendar quarter prior to the effective date of your workers compensation policy.

Note #2: If you are a new business (no prior operations), submit the requested information, for the first complete calendar quarter following the effective date of your workers compensation policy when available.

Note #3: In the absence of specific records for salaried employees, you should assume that each individual worked forty (40) hours per week.

Please preserve your payroll records which formed the basis for this declaration as we will be required to verify the reported information in order for any premium credit to be applied.

Thank you for your cooperation.

Sincerely,

1989 WORKERS COMPENSATION—PREMIUM CREDIT APPLICATION

**MASSACHUSETTS CONSTRUCTION CLASSIFICATION
PREMIUM ADJUSTMENT PLAN**

ALTERNATIVE EXPOSURE BASES

MASSACHUSETTS CONSTRUCTION CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM

The above program is effective 12:01 A.M., January 1, 1991 and thereafter. The program applies to employers eligible for experience rating having exposure in any of the enumerated construction classifications in Massachusetts.

The Massachusetts Construction Classification Premium Adjustment Program is designed to vary an employer's workers' compensation premium by way of a premium credit based upon the employer's average wage level. While the initial determination of any applicable credit is computed on a class-by-class basis, the credit (if any) will be applied to the employer's entire Massachusetts standard premium in order to facilitate the carrier's application of the credit. The program will provide a premium credit to those eligible construction employers paying in excess of \$18.00 per hour on average per construction employee.

The program does not provide for any premium debits. Therefore, rate changes are required for all the applicable classifications in order to offset the premium credits.

The program (see Massachusetts Basic Manual - Special Rule, EXHIBIT 1) shall be administered as follows:

1. Each carrier shall issue a letter, with Application on reverse side, having standardized text (EXHIBIT 2), to any insured having a policy containing one or more of the applicable classifications. One letter must be issued for each qualifying policy. This letter (which must be printed by each individual carrier) should be sent to the insured prior to policy issuance or within sixty (60) days after effective date. The carrier must maintain proof of mailing in its files and make such proof available to the Massachusetts Division of Insurance on request.
2. The insured shall complete the required information and mail the completed form to:

The Workers' Compensation Rating and Inspection
Bureau of Massachusetts
P.O. Box 9005
Boston, MA 02205
Attention: Underwriting Department

3. The Workers' Compensation Rating and Inspection Bureau of Massachusetts will compute the insured's average hourly wage for each classification, the applicable classification premium credit, and the overall policy credit factor. These calculations will be displayed on a Policy Credit Work Sheet (EXHIBIT 3). A copy of this Work Sheet will then be mailed to the carrier.

4. The carrier shall use this policy credit factor in the calculation of the insured's estimated premium at policy issuance. In those cases where the carrier receives the policy credit factor after the insured's policy has been issued, the policy shall be so endorsed by use of Massachusetts Construction Classification Premium Adjustment Endorsement WC 20 04 03 (EXHIBIT 4).
5. Total expected losses used in the calculation of the insured's experience modification will be decreased by the policy credit factor.
6. The policy credit factor is to be applied to the premium determination process directly after the application of experience modification and prior to any deviation and premium discount. This policy credit factor, if available upon policy issuance, must be displayed on the Information Page of the policy (EXHIBIT 5). If the factor is not available upon policy issuance, the required endorsement must be attached to the policy.
7. Upon audit, the carrier shall use the same policy credit factor in the calculation of the insured's final earned premium. Additionally, the carrier shall verify the data originally provided by the insured for the computation of the policy credit factor by reviewing those records upon which the insured's data was originally based. If this process uncovers any errors, revised payroll and/or hours worked, data must be submitted to The Workers' Compensation Rating and Inspection Bureau of Massachusetts. The revised data will be used to calculate a revised policy credit factor.
8. The earned premium dollar modification amount due to the application of the policy credit factor must be reported on unit statistical reports under Classification Code 9046. This amount must be reported on lines D, E, F or G since it is not subject to experience modification (EXHIBIT 6).

Please carefully review the above, including attached EXHIBITS, with your underwriting, auditing and statistical personnel.

MASSACHUSETTS BASIC MANUAL - SPECIAL RULE
MASSACHUSETTS CONSTRUCTION CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM

The Massachusetts Construction Classification Premium Adjustment Program provides for a premium credit for a qualifying policy which contains one or more construction classifications. Only policies subject to experience rating are eligible for the program.

The basis for determining the credit is the total payroll (excluding overtime premium pay) and hours worked for each construction classification for the third calendar quarter of the year preceding the policy inception date as reported to taxing authorities. If the insured did not engage in operations for the complete quarter, then the last complete quarter prior to the policy year inception shall be used, or if there was no complete quarter of operations prior to the policy inception then the first complete quarter after the policy inception shall be used. A credit may be determined for each construction classification by dividing the total payroll, excluding overtime premium pay, by the number of hours worked to arrive at the average hourly wage for the classification. In the absence of specific records for salaried employees, it will be assumed each such individual worked forty (40) hours per week. The credit for average hourly wage is listed below:

<u>Average Hourly Wage</u>	<u>Credit From Manual Premium</u>
\$17.99 or less	0%
\$18.00 - \$18.50	5%
\$18.51 - \$19.00	6%
\$19.01 - \$19.50	7%
\$19.51 - \$20.00	8%
\$20.01 - \$20.50	9%
\$20.51 - \$21.00	10%
\$21.01 - \$21.50	11%
\$21.51 - \$22.00	12%
\$22.01 - \$22.50	13%
\$22.51 - \$23.00	14%
\$23.01 - \$23.50	15%

<u>Average Hourly Wage</u>	<u>Credit From Manual Premium</u>
\$23.51 - \$24.00	16%
\$24.01 - \$24.50	17%
\$24.51 - \$25.00	18%
\$25.01 - \$25.50	19%
\$25.51 - \$26.00	20%
\$26.01 - \$26.50	21%
\$26.51 - \$27.00	22%
\$27.01 - \$27.50	23%
\$27.51 - \$28.00	24%
\$28.01 and over	25%

The total construction classification credit amount, in dollars, must be calculated and then divided by the total policy premium at manual rates - including construction and non-construction classifications. The result would be the percentage credit which is to be applied to the qualifying policy. When calculating the total policy credit, the percentage shall be rounded to two decimal places. (As an example, .1547 rounded to .15 and .1551 rounded to .16.)

The insured shall submit the required payroll and hours worked information to The Workers' Compensation Rating and Inspection Bureau of Massachusetts for calculation of any applicable credit. The carrier shall, upon audit, verify the information that was submitted by the insured and used in the calculation of the credit. If the carrier discovers an error in the original request for policy credit, the revised information must be submitted to The Workers' Compensation Rating and Inspection Bureau of Massachusetts for recalculation. If the insured does not furnish records to verify the payrolls and hours worked originally submitted and used in the calculation of the credit there shall be no credit applied to the policy.

The credit authorized by The Workers' Compensation Rating and Inspection Bureau of Massachusetts, shall appear on Item 4. of the Information Page of the policy. If the credit is not available at the time of policy issuance, the carrier shall endorse the policy to provide this credit information.

Carriers are required to use the approval form to notify all of their insureds, who have one or more construction classifications on their policy, that they may be eligible for a premium modification credit.

"Construction classifications" are those classifications subject to the following code numbers:

3365	5102	5223	5480	5645	6233	8227
3724	5146	5348	5506	5651	6251	9014

**MASSACHUSETTS CONSTRUCTION CLASSIFICATION PREMIUM ADJUSTMENT PROGRAM
WORKERS' COMPENSATION PREMIUM CREDIT APPLICATION FOR 1991**

The Massachusetts Construction Classification Premium Adjustment Program has been proposed for employers engaged in construction operations and is applicable to policies eligible for experience rating with effective dates on or after January 1, 1991.

A special premium calculation, which may result in a premium credit for you, will be based on average hourly pay rates for each classification of construction operations. In order that your premium may be correctly established, please return the completed premium credit application, as shown on the reverse side of this letter to:

The Workers' Compensation Rating and Inspection
Bureau of Massachusetts
P.O. Box 9005
Boston, MA 02205
Attention: Underwriting Department

They will advise us of any premium credit applicable.

If they do not receive this application, your 1991 premium calculation will not reflect any possible premium credit.

For each applicable classification (both construction and non-construction) covering your company's operations in the state of Massachusetts, report the total Massachusetts payroll (excluding overtime premium pay) and the corresponding total number of hours worked for the third calendar quarter (July, August, September) of 1990 as reported to taxing authorities.

Note #1: If you did not engage in construction operations during the third quarter of 1990, the requested information to be provided should then be for the last complete calendar quarter prior to the effective date of your workers' compensation policy.

Note #2: If you are a new business (no prior operations), submit the requested information for the first complete calendar quarter following the effective date of your workers' compensation policy when available.

Note #3: In the absence of specific records for salaried employers, you should assume that each individual worked forty (40) hours per week.

Please preserve your payroll records which formed the basis for this declaration as we will be required to verify the reported information in order for any premium credit to be applied.

Thank you for your cooperation.

Sincerely,

Turn Page Over For Premium Credit Application

MASSACHUSETTS CONSTRUCTION CLASSIFICATION PREMIUM ADJUSTMENT ENDORSEMENT

The premium for the policy may be adjusted by a Massachusetts Construction Classification Premium Adjustment factor. The factor was not available when the policy was issued. If you qualify, we will issue an endorsement to show the premium adjustment factor after it is calculated.

Notes:

1. Attach this endorsement to a policy showing Massachusetts in Item 3.A. of the Information Page when an insured's credit adjustment factor is not available when the policy is issued.
2. An appropriate typewritten entry may be made in Item 4. of the Information Page instead of using this endorsement.

(120,121 + 2,206) Total of Estimated Annual Premium and Mass. D.I.A. Assessment					122,327

- As issued by this Bureau.
- In this example, the Stock Discount (Table 7) was used. Those carriers using the Non-Stock System of Expenses would use Table 8.
- The Mass. D.I.A. Assessment is based on Standard Premium.

STATISTICAL REPORTING

1. The earned premium dollar adjustment amount due to the application of the policy credit factor must be reported on unit statistical reports under Classification Code 9046. This amount must be reported on lines D, E, F or G since it is not subject to experience modification.

Experience Rating and Construction Classification
Premium Adjustment Program

Those classifications to which this program applies will have the manual rate raised above the otherwise indicated average rate so as to provide money with which to pay the discounts. Some insureds in these classes will pay the manual rate with no discount while others will get discounts. Thus the starting points prior to experience rating differ for these risks.

In order to maintain the balance of the experience rating plan the expected losses which enter into the calculation of experience modifications have to reflect these different starting points. The Expected Loss Rate (ELR)¹ in the manual would correspond to the manual rate. Thus expected losses derived from this ELR are the losses we expect for a risk getting no discount from the manual rate. These risks have higher than average expected losses for the class. For risks getting a discount, the expected losses are lower by the amount of the discount. These risks have lower than average expected losses for the class. The ELR times payroll would produce expected losses too high for these risks.

Therefore, the expected losses derived by summing the product of ELR's and payrolls for individual classes will be multiplied by the discount applied to the policy. This will provide an appropriate starting place for comparison with actual losses in the calculation of the experience modification.

The effect will be that large risks who receive discounts will find that their experience modification will be somewhat higher. This makes sense since, to the extent a risk's own losses enter into setting its rate via experience rating, discount is redundant. A risk will always be better off in total getting the discount; the change in experience modification will only partially offset the effect of the discount. Similarly, a risk getting no discount will find its higher manual rate only partially offset by a decrease in its experience modification.

¹Expected Losses = ELR x Payroll

*Classification applicable only in Oregon.

**Classification applicable only in Illinois.

A. INTRASTATE RISKS

Experience rated risks shall be subject to the loss ratio adjustment program (LRAP) provided more than 50% of the risk's total expected losses are generated by one or more of the above classifications.

The rating organization shall adjust the experience modification for all eligible risks in the following manner:

1. Multiply the discount ratio for each of the above classifications by 1.05.
2. Apply the increased discount ratio to the expected losses for each of the above classifications to produce revised expected primary losses and expected excess losses.
3. Recalculate the experience modification using the expected primary losses and expected excess losses as determined in (2).
4. Calculate the following ratio:

$$R = \frac{\text{Risk Total Actual Losses}}{\text{Risk Total Expected Losses} \times \text{Recalculated Experience Modification}}$$

5. Determine the loss ratio adjustment factor by referencing the point at which the R factor calculated in (4) intersects the risk's expected loss total contained in the Credit/Debit Table on Page A-11.

6. Determine the adjusted experience modification by multiplying the recalculated experience modification in (3) by the loss ratio adjustment factor in (5).

B. INTERSTATE RISKS

Experience rated risks with multi-state operations shall be subject to the loss ratio adjustment program (LRAP) provided:

- a. one or more states in the rating have approved the loss ratio adjustment program and,
- b. more than 50% of the total expected losses in at least one approving state(s) are generated by one or more of the above classifications.

The rating organization shall adjust the experience modification for all eligible risks in the following manner:

1. Multiply the discount ratio for each of the above classifications by 1.05, in each state where this adjustment applies.
2. Apply the increased discount ratio to the expected losses for each of the above classifications to produce revised expected primary losses and expected excess losses.
3. Recalculate the experience modification using the expected primary losses and expected excess losses as determined in (2).

† Not applicable in Nebraska effective November 1, 1989; not applicable in Maryland effective July 1, 1990; not applicable in Illinois effective September 1, 1990.

4. Calculate the following ratio:

$$R = \frac{\text{Total Actual Losses in States Where This Adjustment Applies}}{\text{Total Expected Losses in States Where This Adjustment Applies}} \times \text{Recalculated Experience Modification}$$

5. Determine the loss ratio adjustment factor by:

a. Referencing the point at which the R factor calculated in (4) intersects with risk's expected

loss total combined in the Credit/Debit Table on Page A-11.

b. Divide the expected losses for those states where this adjustment applies, by the total expected losses for all states in the rating.

c. Multiply (b) times the credit or debit determined in (a).

6. Determine the adjusted experience modification by multiplying the recalculated experience modification in (3) times the loss ratio adjustment factor in (5).

★

* Not applicable in Nebraska effective November 1, 1989.

**NEW YORK COMPENSATION INSURANCE RATING BOARD
CONTRACTOR CLASS STUDY**

ALTERNATIVE EXPOSURE BASES

NEW YORK COMPENSATION INSURANCE RATING BOARD

200 East Forty-Second Street, New York, New York 10017

Telephone (212) 697-3535 Fax (212) 972-1393

Expressly Prepared For:
General Building Contractors
of New York State, Inc

Subject: Basis of Premium

At the request of the General Building Contractors of New York State, Incorporated, a study was undertaken by the Rating Board to review the proposal for introduction of a premium determination method which would exclusively use hours to measure exposure to hazards.

General

In connection with this review, several hundred employers were subjected to physical audits whereby their accounting records were examined to establish whether complete and verifiable records of "hours worked" were available. Our study showed that 53% of the employers did have some form of hourly records. However, it is of significance that the balance did not keep any hourly records at all. And it is also important to mention that none of the employers that maintained hours worked records had their hours summarized or broken down by categories of work, e.g., concrete construction, factory, clerical, outside sales, etc.

It is of note that the availability of "hours worked" records changed rather dramatically when certain categories in the construction industry only were reviewed. This part of the study disclosed that over 90% of the higher paying employers did have hours worked records available, and about 60% of the lower wage paying employers in that industry had hours worked records available.

Background of Current System

The present system involves premium charges based on a uniform rate per hundred dollars of payroll for each employee, subject to the type of work involved. If the payroll method was replaced with the number-of-hours worked per employee, we must all ask ourselves how would this affect the current pricing system as it relates to an employers premium?

The current rate per each \$100 of payroll for workers compensation premium is predicated on the anticipated *total payrolls* for each industry and the expected losses for that industry. This system must produce a sufficient amount of premium to cover the *actual* losses for each industry. *It is important to note that this premium "need" to pay actual losses and expenses does not change regardless of the basis of premium; e.g., payrolls, hours, etc.* If the Basis of Premium was changed to other than payroll, then it is expected that there would be a redistribution of the needed premium among the employers in each classification.

Hours Worked V. Use of Payrolls

How would that redistribution be made? Well it would come about naturally, based upon the reported exposure to operations (hours.) However, this system would be affected considerably by the fact of whether an employer did or did not keep records. And of course, whether the records were maintained accurately, and whether the "hours" could be verified somehow.

In theory, the hours-worked method would appear to be the most reasonable way of developing workers compensation premiums. But there is a most serious negative downside in relying solely on hours-worked that must be considered. And the risk is that hours-worked will indeed be subject to inaccuracies, discrepancies, and abuses.

What would be the difference between an hours-worked system and the use of payrolls? The difference involves verification, because payrolls are physically paid to employees, checks are drawn on banks, and multiple tax reports must be completed by employers and filed with governmental agencies who periodically audit these filings. These verification capabilities generally assure that the payrolls used are the payrolls expended, and therefore, are the proper payrolls to be taken by insurance company auditors. This is not the same scenario with the use of hours-worked because as already stated, in too many cases the hours are not available and are not verifiable. Yet, the loss *need* remains the same. Consequently we believe that those employers who maintain good records will pay a greater portion of the premium need than those who do not keep accurate and verifiable records.

As an incidental concern, the auditing of hours by insurance carriers will become more expensive and necessarily generate higher expenses to be added to the "rate". For example: if an employee earned \$24,000 per year, this would currently involve (240) \$100 units of payroll. Translating this into units of hours-worked would mean that, without overtime, we might be dealing with about 2000 hours of actual working time per employee, to "verify" per year. Our study revealed a 26% increase in auditing expense to "audit" hours-worked records..

How would an employer check the accuracy of the insurance carrier's billing of hours? With substantial difficulty, we believe. In a 200 employee firm, for example, this could represent 400,000 hours which have to be extracted from unsummarized records provided the hours are available. And what about the problem of trying to separate this by the type of work done; e. g., clerical, outside sales, inside sales, and the whole gamut of contracting classifications? What checks and balances are there for both the insurance company auditor in developing a billing, or the policyholder who wishes to check the charges? This will likely generate more questions and controversies concerning the accuracy of billings. And there would be difficulties when charges for uninsured subcontractors were required where no hours whatsoever are recorded. Inaccurate estimating of non-recorded hours worked would become prevalent, and seriously affect the accuracy of billings as well as the data base used by a rate service organization and the rates it produces. Think about this; will both carriers and policyholders physically go through a set of records independently to add hours, employee by employee, and classification by classification, if the hours are recorded? Would an insurance auditor be able to accept a computer print-out prepared by the insured? No, because the carrier "audit" would then be a meaningless process. And unlike payrolls, when an "hours" audit is completed, there is no way to reconcile this mass of hourly figures with any summary records, such as the employer's disbursements book, general ledger and quarterly and annual payroll tax returns. With

such a system it would not take long before some very creative and imaginative hours-worked records, or reportings, would be made available " For the insurance company's use only".

While no system, or method, is perfect, on balance, the use of payrolls for premium determination purposes is far superior, and more reliable as a measuring tool for developing equitable premium charges from employer to employer. Additionally, it is far less vulnerable; initially to serious auditing difficulties, and subsequently, to improper ratemaking, than an hours-worked method would be.

Review of Ironworkers' Experience

As part of our review, the G.B.C. was requested to provide the Rating Board with a comprehensive listing of their members who are the " higher paying" employers in the State. Ultimately, we were furnished through various sources, including the G.B.C., names of employers engaged in several contracting activities. This list was culled to extract those employers involved with iron & steel erection, because this subject was originally raised with concern for the iron and steel erection employers. The Board then conducted a review of the available experience collected for the three classification codes which comprise the iron and steel erection industry. This experience revealed the following:

1. The high paying employers' payroll and losses for each of the classification codes accounts for a sizable portion of the total experience available for both categories of employers. The actual percentages for each class are shown below:

<u>Class</u>	<u>High Paving Employers</u>	
	<u>% of Payroll</u>	<u>% of Losses</u>
5040 Iron or Steel Erection-Frame Structure	95.0	87.0
5057 Iron or Steel Erection-Frame Structure N.O.C.	95.2	99.4
5059 Iron or Steel Erection-Frame Structure Up to 2 Stories	77.1	88.5

1. The above statistics were based on the data provided to us. There was an "unknown" portion of total experience for these codes, but we believe the unknown experience would likely project to develop similar proportions. Based upon this assumption, it is clear that the experience of the high paying employers is basically responsible for the rate of each classification shown above.

2. In two of the three categories shown (codes 5057 and 5059), the loss experience of the high paying shops is somewhat worse than that of the open shops. If, in fact, a disproportionately higher amount of payroll is presently collected from the high paying employers, then it is reasonable to expect that the ratio of losses to payroll should be lower for the high

paying segment. However, based on the above loss ratios, the higher paying employers incur a disproportionately higher percent of the total losses.

3. Since most of the classification payroll belongs to the higher paying employers, a change to hours worked as a basis of premium will have little or no significance on the total premium paid. Regardless of the premium basis, a specific amount of premium is needed to cover losses and expenses for each industry. Because the experience composition of these classes is largely derived from higher wage paying employers, the bulk of the premium would still come from the higher paying employers, and any new rate structure would self-correct for this regardless of the basis of premium.

Conclusion

We are emphatically opposed to the substitution of "hours worked" as the basis of premium, because it would completely destroy the establishment of equitable premium charges from employer to employer.

It is understandable that the G.B.C. may view the "hours worked" theory as a simplified approach to handling the perceived problem, but we submit that their posture does not recognize the serious pitfalls that are masked within an hours worked system. As already stated, we believe that higher paying members of the G.B.C., under an hours worked basis of premium, would be subjected to paying a substantially higher percentage of the premium needed to cover the losses and expenses for the iron and steel erection classifications than at present.

Members of the G.B.C. may believe that they are presently paying a higher percentage of the needed premium per classification, and support that view with their estimates of a 1/3 disparity in hourly wages. Actually, after application of an improved experience rating and premium discount which high paying employers enjoy, the difference is narrowed considerably.

Systems Development

Richard O. Heard, Jr.
Assistant Vice President

February 26, 1991

Mr. Brett Miller, ACAS
Arthur Andersen & Company
Thirteenth Floor
1345 Avenue of the Americas
New York, New York 10105

Dear Brett:

I have attached our analysis of the costs associated with capturing and implementing an alternative measure of exposure, in addition to the current unlimited payroll. We have gone to some length to explain the industry-wide implications, which would have significant costs. Estimation of these costs would require a survey of insurance companies, agents, and other rating bureaus. I note that Milliman & Robertson's proposal for the NAIC review (for objective 6b) includes mention of this survey approach, and I assume that you would undertake this effort.

Please let me know if you have any questions or need any additional information.

Yours truly,

A handwritten signature in black ink, appearing to read "Richard O. Heard, Jr.", written in a cursive style.

Richard O. Heard, Jr.

In conjunction with the NAIC review being conducted by Milliman & Robertson (M&R), NCCI has been asked to estimate the costs associated with implementing an alternate exposure base. This alternative would be collected and processed *in addition to* the current exposure measure, unlimited payroll. Candidate alternatives identified by M&R include limited payroll, person-hours, and average weekly wage. This response will not attempt to address the efficacy or actuarial fitness for use of one method of measuring exposure over another, but will instead focus on the industry-wide implications and specific NCCI costs associated with implementing such a change.

The costs of implementing a change to the exposure base are manifested in three areas: collecting the necessary information, reporting that information to NCCI and independent bureaus, and using the information in ratemaking and experience rating calculations.

Collection

The exposure measure, whether a derivative of payroll or some other measure, must be collected at the point of sale of insurance. Changes to this measure will therefore require new information to be presented by prospective insureds. Existing agent procedures and systems (e.g. rate quote systems and customer databases) will require modifications. The ACORD application for insurance, the assigned risk application, and any other applications used by independent bureaus must be changed to gather the alternative exposure measure. These types of changes typically require specific filings in each state, complicating the implementation process, as different effective dates are possible.

As with any exposure measure, the information must be readily available and commonly defined at the time of collection. To the extent that measures other than unlimited payroll are less uniformly available or subject to interpretation, agent costs will increase and delays in binding coverage may occur, thus having a detrimental effect on service levels.

Insurance company systems must be modified to accept and process the new application information, and the industry standard policy information page must be changed to display both current unlimited payroll and the alternative exposure measure. Finally, the exposure measure must be verifiable. A measure other than unlimited payroll will have implications on company and bureau costs to inspect and audit insured records to ensure the accuracy of the exposure.

Reporting

Companies report policy coverage information and statistical information to NCCI, independent state rating bureaus, and industrial commissions. Each of these entities will require systems and procedural changes to accept an alternative measure of exposure. Of great importance in determining an implementation date is the close association of the above in using common data reporting formats. With both the Workers Compensation Statistical Plan (WCSP) and policy information reporting, most bureaus including NCCI share standard hard copy and electronic data reporting specifications.

In this regard, all bureaus must make the necessary changes and agree on an implementation date. The following WCSP format change requests are now pending from New Jersey, Texas, and NCCI, with California contemplating a statistical plan rewrite:

- allocated loss adjustment expenses (ALAE);
- deductibles;
- employers' liability;
- four digit year;
- rate deviation percent;
- group policy identification;
- self insurance policy identification;
- small premium policy plan identification;
- employers' rejected risk fund identification; and
- social security number of claimant.

An alternate exposure measure must be added to the list and considered along with the other requested changes. NCCI's Statistics Committee, at its February 7, 1991 meeting, passed the following recommendation:

"That the collection of ALAE on unit reports and annual calls be accomplished in conjunction with other changes required to satisfy the needs of all rating bureaus and users of the data."

This would reduce the incremental cost of reporting an additional exposure measure, while having the likely negative impact of delaying the implementation timeframe until all changes are agreed upon.

These changes will also have cost implications for hard copy reporting, as the current "unit report" format cannot be expanded to accommodate additional data elements. This will change the unit report form factor, requiring changes to manual filing and micrographic equipment and procedures. The changes will also have cost implications for electronic reporting, as the existing data record formats must be expanded to accommodate the additional data. While there is sufficient room on the current exposure record (where payroll is reported) for some of the above requested changes, there is not sufficient room for all.

Usage

Once collected and reported to NCCI, the alternative exposure measure would be used in ratemaking and experience rating calculations. Prior to usage, existing data validation and quality checks would be changed to include the alternative exposure measure. NCCI-company communications, in the form of error reports and turnaround documents, would also be changed, as would manuals and procedures documentation. Finally, ratemaking and experience rating systems would be changed to include the new measure, and existing report formats modified to display the new inputs and results of alternative calculations.

The transition from the existing unlimited payroll to the alternative exposure method must also be considered. Ratemaking and experience rating calculations require at least three years of data, and statistical data are reported 20 months after the policy inception date (with the M&R review now studying the efficacy of using four or five years for classification ratemaking). This will produce a significant lag between the start of collection by the insurance agent and the ultimate use of the measure in ratemaking and experience rating calculations.

Specific NCCI Costs

The cost implications for NCCI implementation of an alternative exposure measure are shown in two ways: as stand-alone costs, assuming no other statistical plan changes were implemented, and as incremental costs, assuming most or all of the other requested changes identified above were also implemented. In all cases, these estimates are rough. More precise estimates can be made later when more details are known about which specific changes would be made, and how the changes would be included in our systems. The cost estimates have been made using \$50 per hour, with a 1,500 hour work year, yielding annual costs of \$75,000 per person-year.

Total stand-alone costs for the required changes are estimated to be approximately 13 person-years of programming and end-user specification and testing efforts, or about \$975,000. Perhaps more importantly, the magnitude of the required effort and the extensive impact throughout nearly all of NCCI's critical business functions would severely inhibit our ability to proceed with other systems development efforts during this time. The incremental costs above and beyond those required to implement the other requested WCSP changes are significantly less, at about 2 person-years, or \$150,000. The costs are explained below in four areas: data reporting, data verification, ratemaking systems changes, and experience rating systems changes.

Reporting

NCCI's keypunch facility (ACS) keys most hard copy policies and all hard copy unit reports received by NCCI, and would key the additional exposure information. Assuming current record counts and an average seven position alternate exposure

field, keying costs would be approximately **\$20,000/year**, both stand-alone and incremental.

Inclusion of a new data element will require a change to the unit report form and to the WCSP tape reporting specifications. Changes will be required in NCCI's up-front processing systems to capture the data. Exposure (payroll) is not currently captured in NCCI's policy issue capture system (PICS), therefore, no incremental costs would be incurred. However, exposure is integral to all NCCI unit report processing systems, and significant changes would be required.

NCCI's up-front report processing systems include the IDV/IMG systems, the Unit Report Control (URC) system, and the unit report database (now under construction). Stand-alone changes to these systems to accommodate an additional exposure data element would require approximately **2 person-years**, or about **\$150,000**. Incremental costs for the changes above and beyond those required to process the other WCSP changes would be negligible.

These estimates assume that all existing printing and filing of mag tape submitted unit reports would be replaced by the new unit report database. If this is not the case, significant additional costs would be incurred to adopt a new unit report form factor, including hard copy filing and micrographic processing.

Verification

Two types of verification are applicable: ensuring the reported data accurately represent the true exposure presented by the insured, and ensuring that the data in NCCI's systems matches that reported to NCCI. For the former, NCCI conducts risk inspections and, in some states, premium audits. The costs (which have not been estimated) for these activities would increase to include an alternate exposure measure, primarily due to the increased difficulty in auditing the information. The costs for internally editing and validating the reported data would be negligible. However, existing data validation routines and reports produced as part of the classification ratemaking process would be affected; these are discussed below.

Ratemaking Calculation

NCCI's classification ratemaking systems begin with WCSP (unit report) data and include data validation and summarization by class code, for a given state and reporting period. The final product is a variety of reports, including A-sheets (pure premiums), schedule Z, and NC-235 formats for exposure, premium, and loss totals by class. Changes would be required throughout these processes, including the production of final rates showing calculations with both exposure measures (current unlimited payroll and the chosen alternative measure). Stand-alone changes to these systems to accommodate an additional exposure data element would require approximately **5 person-years**, or **\$375,000**, including end-user

involvement for requirements and testing. Incremental costs for the changes above and beyond those required to process the other WCSP changes (assuming the changes would include the ALAE separation) would be approximately 1 person-year, or \$75,000.

Experience Rating Calculation

NCCI's experience rating systems begin with rating data stored from the prior year's rating, governed by a profile that establishes what data are to be included in the calculation. Exposure information is integral to the experience rating calculation in its use in determining expected losses. The inclusion of an alternate exposure measure would require significant changes throughout the experience rating systems, including NCCI's risk directories, the file containing prior rating data (compress files), online inquiry and corrections systems, and the printed experience rating worksheets and related output products.

Stand-alone changes to these systems to accommodate an additional exposure data element would require approximately 6 person-years, or \$450,000, including end-user involvement for requirements and testing. Incremental costs for the changes above and beyond those required to process the other WCSP changes (assuming the changes would include the ALAE separation) would be approximately 1 person-year, or \$75,000.

The total costs for systems changes are summarized below:

NCCI IMPLEMENTATION COSTS		One-Time	Incremental	Ongoing
Reporting	ACS keying IDV/IMG system	2 person-years	0	\$20,000
Verification		?		
Ratemaking		5 person-years	1 person-year	
Experience Rating		6 person-years	1 person-year	
TOTAL		13 person-years \$975,000	2 person-years \$150,000	\$20,000

RE: NAIC EXAMINATION - EXPOSURE BASE

Dear Michael:

I am resending the Cost Relativity/Ratio to Average Wage graphs that I faxed to you on Monday. Additionally, I am supplying the DRAFT of the narrative. As each page indicates, this Report is still preliminary in values, descriptions, and conclusions. The information should thus be released only to the NAIC exam team. The final Report, which will ultimately be released in monograph form, will be forwarded to you upon completion.

I am confident that this material will be of great value to you. Please call if concerns arise.

Very truly yours,

James F. Mallon
JFM/cb

Enclosures

TOTAL PAYROLL/HIGH WAGE PAYERS

Over the last couple of years there has been increasing dialogue regarding total payroll as the exposure base for workers compensation. Concern has been expressed by high wage payers feeling that they are subsidizing the medium and/or low wage payers within the total payroll concept. The intent of this analysis is to put into perspective the cost relationships associated with high wage payers versus low wage payers to determine if there is truly inequity in the system.

There are articles and booklets describing the need for a premium base being exposure sensitive, practical, available and verifiable. Total payroll comes out substantially ahead for workers compensation as practical, always available and verifiable. Manhours as a premium base fails to meet the availability and verifiability criteria as well as not being practical. The workers compensation premium base must also have characteristics that equitably predict the level of losses. The following analysis addresses this area.

Claims Cost Relativity by Pre-Injury Wage

This analysis basically is for the contracting group. Contracting classes can have a substantial variation in high wage versus low wage payers. The addendum defines the data base that was used for this analysis.

Exhibit I shows the average claim cost relativity by average wage range. It reveals that average claim costs rise steadily with increases in the average wage. Previous discussions have generally assumed that the average claim cost would begin to plateau at 150% of the average weekly wage. This is because many states have benefit levels that are two-thirds of the pre-injury weekly wage subject to the maximum of the state average weekly wage. This exhibit illustrates that the average claim cost relativities continue to rise materially and are not leveling off.

Exhibits II and III show the corresponding indemnity/medical average claim cost relativity versus average wage range. Again, a material increase is exhibited, especially for indemnity benefits.

Exhibit IV gives a perspective as to why the average claim cost continues to rise. The average duration associated with each of the ranges above 0.25 increases as the average wage increases. This implies that higher pre-injury weekly wages being earned are associated with longer durations. Higher wage earners have a greater expectation from medical care. Higher wage earners tend to be in more urban areas which have access to a greater variety of medical specialists and state-of-the-art medical technologies all of which carry with them higher medical costs. Additionally, one could expect the duration to increase due to additional knowledge of the workers

compensation system that a higher wage earner generally has. Also, most union shops, which generally are higher wage earners, have in-depth knowledge as to all associated benefit programs including workers compensation. This is not intended as a negative comment. It is a realization that the more knowledgeable individuals are about their benefits, the more the potential use of them exists.

Exhibit V summarizes the total claim cost relativities from Exhibit I into two wage groups: above and below 1.25 times the average wage. As mentioned previously, weekly benefits generally are two-thirds of the pre-injury wage subject to a maximum weekly benefit equal to 100% of the state average weekly wage. As such, one would expect that claim costs on workers with pre-injury wages greater than 1.5 times the average wage would be subject to limitation. However, since the wage relativities in this study are based on contracting classes which have a higher average wage than statewide, we would expect that the index at which the maximum applies to be lower. An analysis comparing maximum weekly benefits to contracting average weekly wages indicates that the maximum weekly benefit applies at approximately 1.25 times the contracting average weekly wage. Therefore, the grouping of contracting claimants above a 1.25 pre-injury wage relativity reflects claims that would have been subject to the limiting effects of the maximums.

If benefits paid, both medical and indemnity, were exactly proportional to wages, the claim cost for a high wage earner would equal the claim cost for the low wage earner times the relativity of their wages. In Exhibit V, this would mean that the high wage group's claim cost relativity would equal 1.67 (.85 x 1.57/.80) if a 1 to 1 proportion applied. However, the flattening influences of maximums reduce this somewhat to 1.43. This implies that the loss ratio relativity between high and low wage earners is .86 to 1 instead of 1 to 1. This is derived as follows:

	(1)	(2)	(3)
<u>Wage Range</u>	<u>Average Wage Relativity</u>	<u>Average Claim Cost Relativity</u>	<u>Average Loss Ratio Relativity (2)/(1)</u>
1.26 and up (High)	1.57	1.43	
0 to 1.25 (Low)	0.80	0.85	
High/Low	1.96	1.68	0.86

This indicates the high wage payer receives 86% (1.68/1.96) as much back of his premium as a low wage payer. What this basically implies is that if \$10 is the average wage, then \$15.70 would be the average wage for the high wage payers (1.57 x \$10) and \$8.00 for the low wage payer (0.80 x \$10). Further, if \$10,000 was the average loss, then \$14,300 would be the average loss for the high wage payer (1.43 x \$10,000) and \$8,500 for the low wage payer (0.85 x \$10,000).

Revised Experience Rating Plan

There has been a recent change to the Experience Rating Plan which generally has made the plan more responsive, especially for an employer with premium under a quarter of a million dollars. This plan has currently been approved in 30 states. To illustrate how the Revised Experience Rating Plan responds to different wage payers, a number of examples were run through the plan.

The examples were for a group of "large risks" and a group of "small risks" for both high and low wage payers. The two assumptions that went into each of the individual cases for the high wage/low wage payers were that both had the same number of employees, and the loss ratio relativity was 85% (the previous analysis indicated .86). In other words, a number of \$75,000 risks (large risks) were generated under the low wage scale. Each risk had a different loss distribution. For each of those cases, an experience mod was developed. For the comparable high wage payers at 2.0 times the average wage, the risks would have \$150,000 in premiums, with severities at 1.7 times the low wage risks' losses reflecting the aforementioned loss ratio relativity (wage relativity x loss ratio relativity = severity relativity; $2.0 \times 85\% = 1.7$). Experience mods were generated for those cases. In addition, average wages of 2.5 and 3.0 times as great were also run with comparable loss relationships. The same analysis was run again for small risks (\$12,500 low wage premium). The following is a summary of the output from the analysis as shown in detail on Exhibit VI:

	<u>Average Experience Mod</u>		<u>Average Experience Mod Relativity (H/L)</u>
	<u>Low Wage</u>	<u>High Wage</u>	
<u>High Wage = 2.0 x Low Wage</u>			
Large Risk	1.04	.90	.87
Small Risk	1.06	.95	.90
<u>High Wage = 2.5 x Low Wage</u>			
Large Risk	1.04	.87	.84
Small Risk	1.06	.93	.89
<u>High Wage = 3.0 x Low Wage</u>			
Large Risk	1.04	.85	.82
Small Risk	1.06	.91	.87

Each of the modifications shown are an average of five cases with different loss ratio assumptions and different size of losses under the constraints indicated. The low wage average mod stays the same because it is the base, whereas the high wage experience modification varies due to the average wage being paid each employee for the different examples. The actual modifications are not as important as the relativities between high and low wage payers. As one can discern, a substantial differential results in the modifications being produced for the high wage versus low

wage payers in all scenarios (between .82 and .90). In all cases the average high wage payer receives the benefit of the Revised Experience Rating Plan due to his pre-defined higher wage versus loss ratio relativity indicated previously. This suggests strongly that the average experience modification will materially change the high wage/low wage payers' standard premium relativities, probably in the range of 10% to 20%. This is approximately the shortfall indicated previously from the claim cost wage relativities.

Premium Discount

Premium Discount is a reflection of cost savings associated with the size of premium. In our examples cost savings would be relevant due to the "same size" employer but different wage levels. The premium discount for a \$5,000 policyholder is zero, whereas, the premium discount factor for a \$10,000 policyholder is 5.4%. The credit for the \$20,000 risk is 8.2% of premium, while for the \$50,000 risk it's 9.8%, and for a \$100,000 risk, the premium discount credit is 10.4%. Depending upon the premium size, either a material credit is given when compared to smaller risks or a modest additional credit percentage for larger risks.

Summary

From the analysis above, the following general conclusions can be reached:

- The higher the wage, the higher propensity to have increased average severity per claim.
- The Revised Experience Rating Plan responds substantially to high/low wage payers.
- Premium Discount also brings down the higher wage payers' net premium relationship versus the lower wage payers.

An example of net premium versus manual premium is as follows:

	<u>Low Wage Payer</u>	<u>High Wage Payer</u>
Manual premium	\$20,000	\$50,000
Experience Mod	1.06	.93
Standard Premium	\$21,200	\$46,500
Premium Discount Factor	.917	.903
Net Premium	\$19,434	\$41,977

If the average total loss for a low wage paying contracting risk was \$15,000, and if

an 85% loss ratio relativity for the high wage payer is appropriate, it would imply \$31,875 of losses ($\$50,000/\$20,000 \times .85 \times \$15,000$) for the high wage payer. The following comparison of losses versus net premium would result:

	<u>Losses as % of Net Premium</u>
Low Wage	77.2%
High Wage @ 85% loss relativity	75.9%

The average quantifications performed throughout this analysis imply that the net premium and losses associated with low and high wage payers generate commensurate premiums for the associated losses. Given that loss adjustment expenses, which are the biggest expense item, are highly correlated to the losses implies that insureds, even if they are paying two to three times the average wage, incur benefits that are commensurate with that relationship.

While there are optional rating plans such as retrospective rating or dividend plans that further adjust the individual policyholder's final cost, experience rating and premium discount alone respond well towards achieving equity in premiums charged the high and low wage payers.

Manhours

This analysis demonstrates that manhours would do a gross injustice as a premium base as a reflection of actual exposure. Manhours basically would imply that individuals should pay the same workers compensation premium per employee regardless of the substantially delineated additional benefits the high wage employees receive. This would be contradictory to the facts and would require a substantial subsidy to the high wage payers. This is in addition to the expense of keeping records of hours worked and the difficulty in verification. Further, since manhours is not an inflation-sensitive exposure base, higher annual rate increases would be needed to capture the rise in costs due to wage inflation.

Limited Payroll

Limited payroll also has significant flaws. First, there is the problem of maintaining separate records of limited payroll solely for workers compensation coverage. This would be even more onerous for a multi-state risk due to likely variations in the payroll limit by state. The second and fundamental problem is that limited payroll does not correspond to actual exposure. The earlier exhibits clearly show that claim costs continue to rise with wages in spite of maximum weekly benefits. Third, is the problem of annual updates of the payroll cap to keep pace with benefits. To the

extent to which the limit is kept low through the politicization of workers compensation filings, the inequity of the system would be exacerbated. Further, if the limit were to remain artificially low, the inflation-sensitive benefits of payroll as an exposure base would be lost.

Conclusion

This paper has clearly illustrated the equity of the current system of using total payroll as the exposure base for workers compensation insurance. Alternate exposure bases, such as manhours and limited payroll, have strong disincentives initially from the viewpoint of record keeping and verification. Most important, however, is that total payroll is better in correlating exposure to loss potential, which in turn leads to a more equitable and preferable system.

Addendum

Exhibits I-IV were developed using data from NCCI's Call for Detailed Claim Information (DCI). The DCI statistics used span eight accident years (1980-1987) and twelve states*. Accident years 1988 and 1989 were not used since the expected development on these claims is high. To apply an even development factor would be ignoring the fact that the development is, in fact, not evenly distributed by claim. This would bias any analysis looking to differentiate ultimate loss values by types of claims (in this case by pre-injury wage levels).

The data were normalized to remove wage/cost differences between years and states by indexing each state for each accident year separately, then weighting these indexes to derive the group total. Claims with extreme values were excluded from the database. The edits excluded claims with durations of 0 or greater than 2000 weeks, losses greater than \$1,000,000, and pre-injury wages less than .05 times or greater than 5 times the state average.

The figures were based on statistics for Contracting classes only. Therefore, the costs are compared to an average pre-injury wage index based on just Contracting classes.

The analysis in this paper was done using claim counts to weight the state indexes to total. An alternate study giving each state equal weight produces similar results in the aggregate.

* Over the eight year period, there were thirteen states that were part of the Call for Detailed Claim Information. They include: Florida, Georgia, Hawaii (83-87), Illinois, Kentucky, Louisiana (83-87), Maine, Massachusetts, Michigan, Minnesota, New Mexico (86-87), and Oregon (83-87). Pennsylvania was also part of the DCI Call but could not be used since Pennsylvania class codes do not readily correlate to NCCI codes.

State of Oregon - Workers' Compensation Department

REFINED CONSTRUCTION CLASSIFICATIONS

ADVANTAGES

1. It addresses the specific problem.
2. It is relatively simple to implement.
3. There is precedent for this approach.
4. There would be only minor disruption of the rating system and it should be relatively easy to quantify.

DISADVANTAGES

1. Acceptable definitions of additional sub-classes are not clear-cut.
2. Verification and non-manipulation of further classification criteria would be difficult to maintain.
3. The actuarial credibility of further classifications may be limited.

APPENDIX C

EVALUATION OF NATIONAL COUNCIL ON COMPENSATION INSURANCE STUDY

Discussion of Proposal

The National Council on Compensation Insurance (NCCI) proposed solution to the inequities in the workers' compensation rates due to wage variability is a modification of the Experience Rating Plan for construction employers. This modification consists of two components: (a) an additional credit/surcharge based on expected losses and the ratio of actual losses to expected losses; and (b) an increase of 15 points in the D ratios for each classification. In a subsequent filing made in Maryland, the D ratio adjustment was dropped to 5 points. There are no proposed changes in the rating procedures for non-experience rated insureds.

The credit formula is very general in scope; it does not directly address the issue of inequities due to wage differences. It is designed to correct, in part, the premiums charged to experience rated insureds. As the size of an insured increases, so will the adjustment. Therefore, small experience rated insureds will be charged almost the same premium as under the current formula, with the change being in the direction of

more equitability.

The assumption underlying the increase in the D-ratio is that a higher percentage of losses are expected to be primary losses. We understand from the NCCI that this shift in losses from excess to primary is supported by the actual loss data for experience rated construction employers. The effect of this shift is to lower the premium charged for all experience rated insureds. If it is assumed that the lower wage paying employers also tend to be the small, non-experience rated employers, then it is reasonable to conclude that this is the desired effect. That is, the low hourly wage paying employers currently have a total manual premium that is low relative to that charged the higher hourly wage paying employers. Based on the available data, we cannot evaluate the validity of the selection of 5 or 15 points as the amount of change in the D-ratios.

Since the proposed modification is intended to make the Experience Rating Plan more responsive, the premium charged an insured using the proposed formula will be more volatile than using the current formula. Both aspects of the proposal result in more credibility being given to the actual experience of the insured. The modification formula increases credibility with the size of the insured; whereas, the D-ratio change has a greater relative effect on smaller experience rated insureds. We are not

aware of any strong actuarial support for the increased credibility, particularly for the smaller insureds. This is the result of giving more credibility to the insured's actual experience, even though the expected claim frequency is very low, and, therefore, highly variable.

The NCCI proposal does not address the issue of any inequities in premiums for non-experience rated insureds. Based on the data presented, we do not believe that any conclusions can be drawn regarding inequities among non-experience rated insureds or between experience rated and non-experience rated insureds.

Validity of Conclusions

Using the survey data of all employers answering the wage question, the NCCI states that "Medical benefit costs increase as injured worker's wage increases." However, the three year experience rating data indicate that the opposite may be true. We cannot draw any conclusions regarding the equity of frequency or severity separately based on these data because of the necessary combination of all of the classes. Individual classes have different frequency, severity and rate assumptions which distort analyses on an all-classes-combined basis.

The NCCI also states that "Workers in more hazardous occupations are the ones that receive higher wages." Although this is

intuitively reasonable, the data from the survey are inconclusive with regard to this point. We believe that the primary conclusion that can be drawn relating hazard to wages is that any increase in hazard is less than proportional to the increase in wages. Both claim frequency and pure premiums calculated with respect to wages indicate that the hazard per dollar of payroll is less for the high paying employers.

An analysis of the equity of the NCCI proposal using the experience rating data indicates that some of the existing inequity in the premium is removed. However, it appears that significant inequities may still remain between high and low wage paying employers. We do not believe that data for non-experience rated insureds are sufficient to draw any conclusions, one way or the other. In our opinion the data are inconclusive and no firm conclusions regarding the true magnitude of the equitability problem or the effectiveness of the proposed solutions can be drawn. Given the data limitations that are inherent in the Oregon survey, we believe that the only conclusive finding is that a problem does exist.

Validity of the Sample

We believe that the survey and sampling procedures used by the NCCI are reasonable. However, we have some concerns about the validity of the resulting data. It is possible that different

APPENDIX D

EVALUATION OF FUTURE COST ANALYSTS STUDY

Discussion of Proposal

The Future Costs Analysts (FCA) proposal involves a change in the premium bases used for construction workers in Oregon. FCA proposes that premiums for medical benefits and for compensation benefits with a low maximum be based on hours worked. High maximum compensation benefits would be based on limited payroll. FCA mentions several alternatives to the premium basis change that would produce the same effect, including a credit or surcharge applied based on average hourly wages and an additional experience modification factor applied based on average hourly wages.

Underlying the use of hours worked is the assumption that all three components of loss (frequency, duration, and benefit) are the same per hour worked for all employers in each classification. Concerns regarding the use of hours worked are its lack of responsiveness to claim severity differences among insureds, its lack of sensitivity to inflation, and the availability of accurate and verifiable data. Medical costs from year-to-year are likely to vary more closely with wages than with hours worked, as similar economic forces affect both wages and medical costs. FCA cites the fact that the State of Washington

has used hours worked as an exposure base for fifty years in support of the contention that hours worked can be properly collected. It should be noted that Washington has recently considered changing the exposure base away from hours worked and that actuarial equity was not the sole reason for not implementing a change.

The use of indexed limited payroll as an exposure base implies that both duration and frequency are proportional to hours worked and that the weekly benefit is proportional to the limited average weekly wage. Similar concerns about the feasibility of collecting accurate and verifiable data for limited payroll have been expressed as for hours worked. As with hours worked, there is currently no evidence either way as to whether the data can be collected. However, it should be noted that the industry did actually use limited payroll for many years prior to the 1970's. Further study of this matter is necessary before any concrete conclusions can be drawn.

Validity of Assumptions

In their report, FCA presents the distribution of employers' average wages in support of their contention that wage levels vary significantly within a given class. This distribution includes data from all classifications in the construction industry, and, therefore, may overstate the variability within

class due to potential wage variation in the average wages between classes. Of course, the data by classification would be too sparse to be credible. In addition, while the average wages appear to vary, FCA does not provide a "standard" of variability for comparison.

The use of both the limited payroll and hours worked premium basis assumes that frequency is proportional to hours worked. For at least some insureds, high wages may be a reflection of higher hazard. As discussed in detail in Appendix C, the survey data is inconclusive on this point.

FCA also addresses the issue of whether medical benefits are related to wages. However, unlike the NCCI, FCA concludes that these benefits are independent of wages. All medical benefits are unlimited in terms of total cost. The possibility does exist that the frequency and/or severity of medical benefits can increase as wages increase due to higher hazard. Again, the Oregon survey does not provide any conclusive data on this point.

FCA states in their report that "Indemnity costs generally will be proportional to wages, limited to the wages qualifying for the maximum benefit." They address the frequency and weekly benefit components of the indemnity benefits as being proportional to hours worked and limited average weekly wage, respectively. They

do not, however, discuss the duration component. We believe that the extra wages paid above the maximum may reflect the potential for longer duration of benefits due to higher hazard for many insureds.

In summary, we agree that high maximum indemnity weekly benefits are more directly related to limited than to unlimited payroll. However, we believe that for certain insureds within a classification the wages above the limit may be indicative of an increase in hazard attributable to claim frequency, duration, and the potential for unlimited medical benefits. We do not believe that the data from the Oregon survey is conclusive on these issues.

FCA Comments Regarding NCCI Proposal

One of FCA's concerns regarding the NCCI proposal is the increased impact of a large, fortuitous claim on a small or average sized insured. This increased volatility is caused by both aspects of the proposed NCCI change, as discussed in more detail in Appendix C.

In their discussion of the NCCI's selection of data, FCA states that "there was a very significant difference in the bias against high wage payers shown in the larger group." The two pairs of indexed loss ratios shown are based on the two different data

bases used. We do not have available to us the indexed loss ratios based on the one year unit statistical plan data for the 1,061 matched employers separately. However, a comparison of all 1,458 experience rated risks with the total sample population indicates that such a bias may not exist. The indexed loss ratios for the two groups are as follows:

	<u>1,983 Employers</u>	<u>1,458 Employers</u>
Low Wage Payers	1.23	1.22
High Wage Payers	0.73	0.73

Data regarding the 1,061 matched employers versus all employers regarding biases against union employers indicate that the selection process may actually exaggerate the discrepancy between union and non-union employees, as shown below. Again, the indexed loss ratios were calculated using the unit statistical plan data.

	<u>1,983 Employers</u>	<u>1,061 Employers</u>
Union	0.92	0.86
Non-Union	1.17	1.22

In addition to the above points regarding potential distortions that may have been introduced by the selection of the 1,061

employers, we would like to clarify the fact that the 1,061 employers were the employers, in the total population of 1,983 employers, who responded to the wage question, who were experience rated, and whose employer survey identification numbers could be matched with NCCI experience rating data. Of the remaining 922 employers, 525 were not experience rated and 397 were experience rated but not matched. We found no evidence that the 1,061 insureds were subjectively selected for inclusion.

FCA expresses concern regarding the NCCI's use of indexed loss ratios in measuring equity of the various proposals. They maintain that the revised premium should be measured against future loss experience rather than the losses used in determining the rates. "By the very nature of insurance, it can be expected that claims in the future periods will not replicate exactly the claims from the past." This statement applies to the entire concept of any prospective rating plan as opposed to the measure of equity selected. We believe that whatever biases are introduced by comparing losses and estimated premiums from the same experience period are probably relatively constant between proposals. Also, the limitations of the study, discussed in Appendix C, need to be considered in evaluating the validity of the measures chosen.

SECTION 1 — WHAT IS THE ISSUE?

THE APPARENT ISSUE — premium is determined by multiplying the rate times the total payroll times the experience rating modification. *If* two employers have the same number of employees doing the same things, and *if* the two employers have the same benefit costs, they can end up paying different premiums *if* one employer pays higher wages.

WORKERS COMPENSATION POLICY ABC INSURANCE COMPANY

Class	Rate	Payroll	Manual Premium
1234	7.00	100,000	7,000
5678	4.00	50,000	2,000
9876	2.00	50,000	1,000
SUM			10,000
EXPER. MOD.			.80
STD. PREM.			8,000

WHY THE ISSUE MUST BE CLARIFIED — the fact that higher wages produces higher premium, by itself, is *not* unfair. It is only unfair if benefit costs are not also higher. Actual data shows that:

Workers in more hazardous occupations are the ones that receive higher wages.

SOURCE:
NCCI DETAIL
CLAIM CALL

Historical data shows that total claim costs track closer to total wages.

ANNUAL COUNTRYWIDE INCREASES

Lost time benefits are a function of employee wages. Less than 12% of injured workers receive the maximum weekly benefit.

BENEFIT: WAGE
Weekly benefit directly proportional to weekly wage for 88% of claimants.

Medical benefit costs increase as injured worker's wage increases. This is due to costs from urbanization, level of medical services availability, and other items.

MEDICAL COST FACTORS
Urbanization
Availability
Utilization

Other compensation costs such as rehabilitation, attorney fees, etc., are higher when the claimant's wage is higher.

There is no problem when higher wages generate higher premiums if there are also higher claim costs.

THE REAL ISSUE — is there a category of employer for which the ratio of benefits to premium is too high (the category being subsidized) with another category for which the ratio of benefits to premium is too low (the category that is paying the subsidy).

For a very large insured, the Experience Rating Program today sees that his premium is fully responsive to his benefit costs. As the size of the employer being observed decreases, the employer's premium enjoys more stability, but less responsiveness to his own benefit costs.

FIND ACCEPTABLE BALANCE POINT

The categories of employers for which the question as to whether one group is being called upon to subsidize another are generally defined as union employers versus nonunion employers, or high wage paying employers versus low wage paying employers. The issue is only relevant when there are significant differences among employers that are within the same occupation classification.

TYPES OF EMPLOYERS

First, it is necessary to identify whether there exists a systematic difference in the benefits to premium ratio for the various categories of employers.

Then, if a difference is found, the question becomes: can it be resolved directly by restructuring classification descriptions and/or the steps in determining manual premium?

Another approach is to adjust the current Experience Rating Program, which is an extension of risk classification, to make individual employer premiums correlate more closely with the particular employer's benefit costs.

SOURCE OF CONCERN — two specific segments of the construction industry have been concerned. These are: employers of union labor, and union labor itself.

Public officials have also expressed concern because of their interest in maintaining a workers compensation program which:

provides the maximum fairness (equity) in the way the costs of workers compensation benefits are allocated to individual employers,

and

encourages (and rewards) safety in the workplace.

**FAIRNESS
&
SAFETY**

SECTION 2 – SOURCES OF INFORMATION ON THE ISSUE

INSURANCE STATISTICS – provide information on premium and claim costs. The segregation of this information between high and low wage paying practices of employers, or between union and nonunion employers is not available. This is not information recorded in the course of the ordinary insurance transaction.

<u>Item</u>	<u>Available Information</u>
Premium	Yes
Claim Cost	Yes
Unionized	No
Wage Level	No

SPECIAL SURVEY – was issued with the goal of factually identifying whether or not a problem existed, and if so, what were the unique characteristics of these employers.

Surveyed classifications represented every occupation or industry for every individual or association representative that voiced concern at the numerous public hearings in Oregon.

**Covered Employers In
42 Classifications**

- The list of 42 classifications was developed with the Oregon Insurance Department.
- The survey was issued by the Governor of Oregon, whose Office had selected the firm that did the survey.
- The survey was designed and issued by the firm of Bardsley & Haslacher, Inc. under the direction of Dr. Robert M. Friedman, Vice President.

SECTION 3 – IS THERE A PROBLEM? – WHAT IS IT?

THE ONLY SOURCE OF ACTUAL DATA – to date there is only one source of scientifically collected actual data (as compared to hypothetical examples or arbitrarily selected illustrations) on the fairness of premium paid by wage level of employer, or unionization of employer. That source is the Special Survey.

WHAT THE SPECIAL SURVEY SHOWS

- For employers so small as to not be included in the current Experience Rating Program:
 - There is no bias against union employers as a group.
 - There is no bias against high wage paying employers as a group.
 - Non-experience rated employers in the survey represented 2.2% of the premium (i.e., work force) in the construction industry.
- For employers large enough to be included in the current Experience Rating Program:
 - There appears to be in the majority of the 42 classifications experience which shows a difference in the benefit cost per premium dollar for employers paying more than \$500 per week as compared to those who pay less than \$500. Per premium dollar, high wage paying employers on average result in a lower benefit cost. That is, their benefit to premium ratio is lower.
 - Similarly, per premium dollar, union employers have a lower benefit cost ratio in the 42 classifications.
- As everyone would expect, the results in both of the above instances are not uniform. Some high wage employers have very high benefit costs, and some union employers have very high benefit costs.

**NO BIAS FOR SMALL
(NON-EXPERIENCE RATED)
EMPLOYERS**

BENEFIT COSTS PER PREMIUM DOLLAR

High Wage	–	11% Less
Low Wage	–	6% More

BENEFIT COSTS PER PREMIUM DOLLAR

Union	–	12% Less
Nonunion	–	14% More

- Two important underlying differences were observed in the benefit cost patterns for union employers as opposed to nonunion employers.

1. The number of claims per premium dollar was lower for union employers.
2. Actual "excess" losses for union employers was lower than expected ("excess" losses are those portions of high cost claims that are discounted in determining the actual premium of a smaller employer in the experience rating process).

UNION EMPLOYERS

- Lower claim frequency per Premium Dollar
- Lower than expected "Excess" Claim Cost

SECTION 4 – CRITERIA FOR A SOLUTION

FAIRNESS – is achieved to the extent that there is meaningful relationship for each employer of benefit costs to the premium he must pay. This relationship of cost to premium should be as similar as possible regardless of how the population of employers is segmented or categorized.

ABILITY TO AVOID MANIPULATION – of the premium calculation process by the insurer, the agent, or the employer is imperative if the program is to produce fairness (and equity) from employer to employer. The method of premium computation must be:

- Clearly definable.
- Only require input which is readily available for all employers.
- Fully verifiable by agents, carrier auditors and bureau inspectors.

EFFICIENCY – requires that any additional recordkeeping for all insureds, and insurers be kept to an absolute minimum. It further requires that extra steps in determining premium also be held to an absolute minimum.

MAINTAIN THE SAME TOTAL PREMIUM – is an integral part of any solution. The allocation, or reallocation, of workers compensation costs to individual employers should not change the total premium.

FAIRNESS –

Match Premium to Claim Cost.

NON-MANIPULATIVE

- Clearly Definable.
- Input Available.
- Input Verifiable.

EFFICIENT

Must not create additional work.

PREMIUM

Reallocated without changing total.

SECTION 5 – THE EXPERIENCE RATING SOLUTION

PROPOSED CHANGES

- **Increased responsiveness**—the current Experience Rating Program has reflected a balance between responsiveness to experience and stability of price for individual employers that has been accepted by most industries for many decades. However, in certain segments of the construction industry in certain states discontent has been expressed. The program of additional premium credits and surcharges described in detail in Appendix B, serves to increase price responsiveness to individual employer benefit costs.
- **Less reliance on the average excess benefit cost experience** of all employers in the classification, and more reliance upon the actual experience of the individual employer. This is accomplished by increasing the D-Ratios only for the particular classification, and then only when the individual employers have significant exposure in those classifications.
- **A solution which is problem specific**—does not change the result for those employers where change is not appropriate. Some categories of employers (e.g. non-rated) have not shown evidence of a problem, and should not have their traditional balance of responsiveness to stability changed. This is accomplished by the specific eligibility criteria as described in Appendix B.
- **Does not result in a requirement to increase manual rates to achieve fairness**, but rather achieves price responsiveness through changes in experience rating plan values.

ADDITIONAL CREDITS AND SURCHARGES

- **Lower Actual Claim Cost Reduces premium.**
- **Higher Actual Claim Cost Increases Premium.**

- **Reduce Expected Excess Costs.**

- **Solution is Problem Specific.**

- **Does Not Increase Rates.**

SOLVES THE REAL ISSUE – which is to more closely align the premiums of individual employers with their actual benefit costs.

- Reduces the premium of employers with low benefit costs per premium dollar.
- Increases the premium of employers with high benefit costs per premium dollar.
- Further encourages employer safety actions by increasing the premium reduction for good results and increasing the premium surcharge for poor results.
- Is problem specific. It addresses the real issue rather than arbitrarily reducing the premium of all employers in a particular category, whether they deserve the reduction or not—and arbitrarily increasing the premium of all of the remaining employers, whether they deserve it or not.
- Does not increase the work, nor overhead costs, of employers, agents or carriers.

SOLUTION

- Increases Fairness.
- Encourages Safety.
- Problem Specific.
- Efficient.

APPENDICES

APPENDIX A

Identification of Premium Inequities

With the receipt of the responses to the employer survey, NCCI now possessed the capability of comparing an insured's actual premium and loss experience with the characteristics of his operation. The first step in this process was a matching of the survey responses to the workers compensation experience incurred under policies effective between July 1980 and June 1981, inclusive. Inasmuch as the concerns expressed over the equity of the current rating system centered around relative wage levels, this matching process was only performed for those 1,983 insureds who completed questions 22 and 23 under the survey. This first gathering of insurance data was also united to the premium and loss experience incurred under the classification for which the employer was surveyed. The insurance statistics gathered included the following for the insured's surveyed classification:

- Total Payroll
- Manual Premium (1980 Rate x Payroll)
- Standard Earned Premium (Manual Premium x Experience Rating Mod)
- Number of Claims (Both lost time and medical only)
- Incurred Indemnity Losses
- Incurred Medical Losses

Each employer was categorized according to his average pay scale in \$100 brackets and the insurance experience summarized for the employers within each bracket. The results of this summarization did indeed portray that in the surveyed classification the high paying employers generated better loss ratios than low paying employers. A clear distinction could be made for those employers paying an average of more than \$500 per full work week versus those paying less than \$500. The results of this comparison can be seen in Exhibit 1.

A similar comparison was made between union employers and non-union employers with the knowledge that union employers are generally the higher wage payers within any particular trade and, thus, classification. Again, discernable differences in loss ratios in the surveyed classifications were apparent where the loss ratio for the union employers was 10% better than average (index of .90) and the non-union 21% worse (index of 1.21). The results of these comparisons are shown on Exhibit II.

In order to isolate the problem further an examination of the premium and loss experience of the surveyed classifications for risks not eligible under the experience rating plan was made. These risks represented only 2% of the premium volume and showed that no clear loss ratios differences exist (see Exhibit III).

While these analyses did portray premium inequities, they did exclude the premium and loss experience incurred in any other classes by those employers and was based upon only one year of insurance data. In order to expand the analyses and ensure that the loss ratio patterns extended over more years, a match was made against the employers' insurance data utilized in the experience rating plan. Of the original 1,983 insureds, 1,061 were experience rated for whom a match could be made between the survey response and the rating data. The experience represented three policy years of premium and loss data (1979, 1980 and 1981) and included all of the workers compensation experience incurred by those employers. As seen in Exhibits IV and V the same loss ratio patterns existed for union/non-union comparisons and high/low wage payers.

APPENDIX B

Experience Rating As A Solution

While wage levels were focused upon by the consumers as creating inequities in the current system, pay practices by themselves will not necessarily create problems. If all the employers in the same classification paid their employees similar wages, even though they may be extremely high, inequities would not occur as the rate would contemplate those wage levels. It is only where the classification plan groups dissimilar insureds, including high and low wage payers, into the same classification that inequities will emerge. It is exactly this case that was demonstrated in the previous section and, thus, actual loss experience did not coincide with the expected loss experience as predicted by the employers' level of premium.

The experience rating plan acts as a natural extension of the classification system. It is intended to introduce more equity into the rating system by comparing an individual employer's actual loss experience to his expected loss experience. A modification to the employer's premium is made as a result of that comparison. The experience rating plan must, of course, balance between the need to be responsive to an employer's loss experience and, yet, be relatively stable. This balance is achieved by placing emphasis upon the occurrence of a claim as opposed to the size of the claim, with the claim size having more significance in the rating as the size of the employer increases. This is accomplished in the experience rating process through the separate analysis of what is termed "primary" and "excess" losses. The key element in the level of emphasis to be placed upon expected claim frequency in the experience rating plan is the D ratio, and 100% minus the D ratio.

While the experience rating plan was designed so as to limit the degree to which a smaller employer's premium could change, it should have operated to eliminate most, if not all, of the differences in loss ratios for large groups of insureds. Inasmuch as the current experience rating plan did not respond sufficiently to the better than expected loss experience of the union employers as a group, it needed to be made more responsive to the employer's actual loss experience. Therefore, as the first part of the solution, NCCI proposes superimposing an additional credit/debit approach to the current experience rating plan.

The first step in the process is determining to what extent the experience rating plan adjusted the employer's level of expected losses through modification of his premium to coincide with his actual loss experience. This comparison can be drawn by dividing the employer's actual losses by his expected losses times the experience rating modification. To the extent that this ratio is greater or less than 1.00, the desire for pure stability limited the responsiveness of the experience rating plan. A ratio of less than 1.00 implies better loss experience, while a ratio greater than 1.00 implies worse loss experience.

By superimposing additional premium credits for ratios less than 1.00 and debits (surcharges) for ratios greater than 1.00, the experience rating plan can be made more responsive to an individual's actual loss experience. There, of course, still needs to be a balance between responsiveness and stability. If the plan were made so as to be completely responsive, the whole concept of insurance is contradicted.

The NCCI, therefore, began analyzing the operation of the current experience rating plan by size of insured and by the distribution of their loss experience within each size category. Alternative combinations of credits and debits were tested so as to restrain the amount by which an individual insured's premium may change from year to year, while at the same time achieving enough responsiveness so as to minimize the inequities in the current system. The attached Exhibit I is the resultant combination of additional credits and debits. It is produced from the formula shown at the bottom of the exhibit that grades the credits and debits both as to size of insured and as to the ratio of his actual loss experience to his modified expected loss experience.

In examining the loss experience for the various groups, NCCI observed another difference between union and non-union employers. Union employers incurred almost 15% less actual excess losses than expected, in addition to having a somewhat lower claim frequency per dollar of payroll. As noted earlier, it is the D ratio and 100% minus the D ratio that is the key element in placing emphasis on claim frequency and developing expected excess losses to be incorporated into the rating process. Therefore, the NCCI also proposed a 15 point increase in the otherwise calculated D-ratios of each of the 42 classifications when rating an eligible insured. This has the effect of placing more emphasis upon primary losses in the rating process when claims occur.

Since the experience rating modifications are developed based upon an insured's entire workers compensation experience, it

was necessary to measure the equity of the proposal using all of the classification data for the surveyed employers. The results of these tests showed that the proposed solution equalized the high wage/low wage and union/non-union modified expected losses (and thus premium) and actual losses through revised experience rating modifications to be applied to each insured's premium in the following way:

	<u>Indexed Ratio</u>
Union	.98
Non-Union	1.02
High Wage	.98
Low Wage	1.01

In order that the program not apply to those insureds with only incidental exposure in one of the affected classes, the NCCI proposes limiting the revised rating procedures to those insured who have a majority of their expected losses in the offsetted classifications (i.e., if the sum of their expected losses in the classes exceeds 50%). Testing this eligibility rule showed that 6,100 insureds out of 7,600 with any exposure in the offsetted classes qualified for the program.

Preliminary tests on these insureds showed that there will be a negative off-balance between the total premium produced by the NCCI proposal for construction classes and the current premium produced from these classes. In order to maintain the same overall total premium, the off-balance will be reflected through an adjustment in the expected loss rates.

OREGON SURVEY ON PREMIUM EQUITY FOR WORKERS' COMPENSATION INSURANCE

This report reports on the method used to collect information for a study mandated by the Oregon Legislative Assembly on equity of premium for workers' compensation insurance.

The data were collected and compiled for the National Council On Compensation Insurance (N.C.C.I.) by Bardsley & Haslacher, Inc., an independent and impartial research organization with operations in the Western United States.

Purpose

During the 1983 Session of the Oregon Legislative Assembly, a number of highly technical questions were raised on equity of premium for workers' compensation insurance.

It was concluded that there was insufficient empirical evidence to guide legislators in determining if remedial steps were required, and, if so, what they should be.

At the close of the Session, the Insurance Commissioner was directed to undertake a study in cooperation with the National Council On Compensation Insurance on equity of premium issues in Oregon and to provide recommendations for legislative actions to the 1985 Legislative Session based on the research.

Bardsley & Haslacher, Inc., was commissioned to conduct a survey of companies and individuals carrying workers' compensation insurance in construction occupations. The data collected were provided to the National Council to be used in conjunction with other information to arrive at recommendations, if warranted, for changes in the basis of premium.

Survey Format

The survey was conducted by the research organization using a mail panel method. This involved contacting potential respondents up to three times to obtain a completed questionnaire.

The initial contact was by mail and included a cover letter from the Governor of Oregon, copy of the survey questionnaire, and stamped return envelope.

In the cover letter, the Governor explained the purpose of the project, requested participation, and assured participants of complete confidentiality of responses.

A second contact was made via telephone by the research organization with those who did not reply approximately two weeks after the initial mailing. The purpose was to determine if the survey was received, answer any questions, and encourage participation.

Approximately three weeks later, remaining non-respondents were sent a second questionnaire, cover letter from the research organization requesting return of the survey, and a postpaid return envelope.

No further contacts were made.

All survey instruments and related materials are appended to this report.

Survey Sampling Plan

This was a census survey. In other words, an attempt was made to obtain participation from the reported total population of insureds in the state covered by workers' compensation during the last three years in 41 construction occupations.

The unit of analysis was company or individual carrying the workers' compensation insurance policy.

To avoid sending multiple questionnaires to companies with coverage in more than one construction occupation, and thus discouraging returns, insureds in each construction occupation were ranked in descending order by amount of payroll relative to other insureds in the same occupational category.

In cases where the insured was covered in more than one occupational category, the construction occupation with the highest rank, accounting for the most payroll relative to the total was selected.

For those few situations where the insured had two occupations with the same rank, the percentage of payroll relative to the total payroll in the job class was examined, and the occupation accounting for the larger percentage was chosen for inclusion in the study.

Using this system of selection, 75% of the total payroll in the 41 construction classifications, or 8,291 insured companies or individuals, were designated for inclusion.

Pretest

Proposed questions were provided by the National Council On Compensation Insurance, which the research organization put into questionnaire form in preparation for pretesting.

The draft questionnaire was finalized on November 17, 1983, and pretested beginning on December 5, 1983, with respondents from construction occupations listed in the table below

PRETEST SAMPLE DESIGN: 1/

<u>Occupational Classification</u>	<u>Sample Size</u>
5057 - Iron Or Steel Erectors (NOC)	29
5551 - Roofing (All Kinds)	208
5651 - Carpentry - Multi-Family Dwellings	197

1/ The total population of reported insureds is larger than the sample size. The difference is due to duplicate N.C.C.I. listings and insufficient information for mailing. Actual number of insureds is: 5057 = 33; 5551 = 221; and, 5651 = 221.

The pretest sample design was a purposive type. In other words, companies were selected only if they had payroll in one of the three pretest occupational categories.

In cases where a company or individual employed workers in multiple construction classifications, it was selected only if its payroll in one of the three pretest occupations was larger relative to any other construction category in which it employed covered workers.

The pretest mail panel was completed on January 27, 1984, with results as shown in the table below

PRETEST RESPONSE RATE:

<u>Occupational Classification</u>	<u>Sample Size</u>	<u>Return Rate</u>
5057 - Iron & Steel Erection (NOC)	29	38%
5551 - Roofing (All Kinds)	208	54%
5651 - Carpentry - Multi-Family Dwellings	197	45%

Analysis of pretest findings led to minor changes in question wording and survey format in preparation for execution of the full survey. These were reviewed and approved by N.C.C.I. principals assigned to the project on February 6, 1984.

Survey Implementation

The full survey was executed in two phases, the first commencing on February 15, 1984, and the second beginning on March 9, 1984.

The execution was preceded by a publicity campaign conducted by the National Council on Compensation Insurance, and its Oregon Office, to create awareness of the project and encourage completion and return of questionnaires.

Each phase consisted of a full mail panel, including an initial mailing of a cover letter, questionnaire, and return envelope; a second contact with non-respondents by telephone or mail, depending

on availability of a telephone number; and, a follow-up mailing to remaining non-respondents.

The table below shows the number of potential respondents in the sampling frame and number of surveys mailed and delivered. The difference between the total potential respondents and the number of questionnaires delivered is due to surveys returned as undeliverable by the post office, duplicate listings on N.C.C.I. records, and insufficient address information for mailing.

In total, there were 7,816 potential respondents covered by workers' compensation insurance during the last three years in 38 construction occupations. This excludes three occupations surveyed in the pretest, and one classification (5069) that has a negligible payroll in Oregon.

Of this number, 81% were included in the mail panel and sent questionnaires, or 6,294 in total, while the remainder were undeliverable by the post office, duplicate listings on N.C.C.I. records, or lacking sufficient information for mailing.

The percentage of questionnaires undeliverable by the post office was 11% of the sampling frame, or 851 in total.

The full disposition of the survey mailing is shown in the next table

N.C.C.I. SAMPLE DISPOSITION

<u>Occupational Classification Number</u>	<u>Total Listing</u>	<u>Mailed & Delivered</u>
3724 - Millwright Work	360	277
3726 - Boiler Installation	31	23

N.C.C.I SAMPLE DISPOSITION: (CON'T)

Occupational Classification Number	Total Listings	Mailed & Delivered
5022 - Masonry	234	193
5040 - Iron & Steel Erection	28	23
5059 - Frame Structures	35	27
5102 - Door Frame Or Sash Erection	36	25
5103 - Plumbing	509	406
5190 - Electrical Wiring	495	401
5213 - Concrete Construction	172	137
5215 - Concrete Work	231	189
5221 - Cement Work	315	257
5348 - Tile Work	84	68
5403 - Carpentry	402	321
5437 - Carpentry (Cabinet Work & Interior Trim)	231	187
5445 - Wall Board Installation	226	169
5462 - Glazier	115	87
5474 - Painting Or Paper Hanging	352	295
5479 - Insulation Work	154	107
5506 - Street or Road Construction	207	172
5507 - Cleaning Right- Of-Way	163	140

N.C.C.I SAMPLE DISPOSITION: (CON'T)

Occupational Classification Number	Total Listing	Actually Mailed
5508- Rock Excavation	29	27
5511- Logging Road Construction	232	210
5538 - Sheet Metal Work	403	327
5606 - Contractors	155	118
5645 - Carpentry Construction	1,494	1,187
6003 - Pile Driveways	21	16
6005 - Jetty Or Breakwater Construction	9	8
6204 - Drilling	88	71
6217 - Excavation	375	310
6229 - Irrigation & Drainage System Construction	100	79
6306 - Sewer Construction	90	67
6319 - Gas Mains Connection Construction	123	107
6325 - Conduit Construction For Cables	44	34
6400 - Fence Construction (Metal)	84	72
7538 - Electric Light Or Power Line Construction	22	17

N.C.C.I SAMPLE DISPOSITION: (CON'T)

<u>Occupational Classification Number</u>	<u>Total Listing</u>	<u>Actually Mailed</u>
7500 - Telephone Or Telegraph Company	98	83
7501 - Telephone, Telegraph, Or Fire Alarm Construction	30	22
7505 - Burglar Alarm	<u>39</u>	<u>35</u>
Total	7,816	6,294

The mail panel was concluded on May 11, 1984, the last day for receipt of completed questionnaires.

The overall (mean) average response rate (weighted) was 66%. The highest return was 88% from Pile Driveways and Drivers, while the lowest was 49%, respectively, for classifications 5445 -- Wall Board Installations Within Buildings, and 7500 - Telephone or Telegraph Company.

Rates of return for each job classification can be seen in the table below

WORKERS' COMPENSATION SURVEY RETURNS

<u>Occupational Classification</u>	<u>Surveys Sent</u>	<u>Surveys Received</u>	<u>% Returned</u>
3724 - Millwright Work	277	189	68%

Non-Respondent Survey

A survey of non-respondents was carried out among those who did not return a completed questionnaire after three contacts.

The purpose was to determine rationales for not responding.

There were a variety of reasons given for failing to complete the survey. Most often it was stated the survey was not received or not filled out because of lack of time.

The non-respondent survey was conducted by telephone with a random sample of 103 insureds for whom a telephone number was available.

All calls were made from May 11 to 15, 1984 by trained telephone interviewers from the central location telephone interviewing facility of the research firm. An interviewer-supervisor constantly monitored the effort.

The interviewer began by asking non-respondents if the occupation about which they had been sent a questionnaire was accurate.

Here is how the question was put

"First, your firm's worker' compensation policy indicates that you employ workers who are classified in class code (INSERT CLASS CODE), working in (INSERT CLASS DESCRIPTION). Is this accurate?"

In total, 91% of the non-respondents said the class code for which they had been sent a questionnaire was correct.

Next, the survey sought to determine the status of the non-respondent's firm.

Well over eight out of every ten called indicated they were actively in business, as shown in the next table

CURRENT STATUS OF NON-RESPONDENT FIRM:

	<u>3</u>
Actively In Business	84%
No Construction Operations In Last 12 Months	4
Not In Business.	4
No Employees In Job Class	4
No Work Bid In Last 12 Months	3
Other.	<u>1</u>
Total.	100%

Sample Size: (103)

Two approaches were used to ascertain rationales for not returning a completed questionnaire.

First, the following open-end question was posed

"Would you mind just indicating the reasons why you didn't happen to complete and return the questionnaire you were sent?"

Second, a closed-end question was asked along the same lines, but with specific answer categories to choose from.

There is a high degree of consistency in answers using the two types of questioning. The most frequent answers to both queries are that either the non-respondent did not receive a questionnaire, or received one but was too busy to complete it.

First, here are the rationales for not responding using the open-ended questioning approach.

REASONS FOR NOT RETURNING COMPLETED QUESTIONNAIRE (OPEN-ENDED):

	<u>2</u>
<u>Did Not Receive Questionnaire:</u>	35%
"Don't recall seeing questionnaire." "Might have been mistaken for junk mail." "Perhaps lost in the shuffle." "Never received."	
<u>To Busy:</u>	33
"Too busy to fill it out." "Looked like it would be too much paper work." "Manager too busy."	
<u>Not Necessary:</u>	17
"Didn't think it was necessary." "Didn't understand how it could affect anything as far as workers' compensation was concerned." "No employees."	
<u>Sent It In:</u>	12
"Returned it." "Returned it twice." "Returned second questionnaire."	
<u>Not In Business:</u>	2
<u>Undecided:</u>	<u>2</u>
<u>Total:</u>	101% 1/
<hr/>	
Sample Size:	(103)

1/ Adds to more than 100% due to multiple reasons.

The closed-end follow-up question asked was

"Just to clarify your reasons, which one of the following reasons that I will read best explains why you didn't happen to complete and return your questionnaire?"

Answers mirror those previously stated

REASONS FOR NOT RETURNING COMPLETED QUESTIONNAIRE (CLOSED-ENDED):

	<u>3</u>
Never Got Around To It	22%
Never Received Questionnaire	22
It Was Misplaced	15
It Was Returned.	10
It Was A Waste Of Time	9
Didn't Think It Applied To Company	6
Too Long	4
Didn't Have Access To Information.	3
Forgot To Return It.	1
Other.	<u>7</u>
Total.	100%

Sample Size: (103)

The claim of not having been sent a survey by between approximately one-fifth and one-third of non-respondents is inconsistent with records of the research company, which show that all those telephoned for this follow-up study were sent two questionnaires.

However, it is possible that the interviewees did not personally receive a survey as N.C.C.I. records contain only firm names and not those of individuals.

Records of those indicating they returned the questionnaire, or returned two questionnaires -- approximately 10% -- indicate that

in a few instances a completed survey was sent back to the research company. When the record keeping for the total survey effort was brought up to date, the change in status of these participants was made.

Other reasons for not returning a completed questionnaire -- which constitute the rationales of the plurality -- "too busy," "didn't think it was necessary," etc. -- cannot be explained without further research on attitudes of insured individuals and companies, which is beyond the scope of this project.

Verification Of Responses

The research firm and Oregon Council On Compensation Insurance (O.C.C.I.) cooperated in a small study to verify answers of respondents.

The research company furnished O.C.C.I. with names of insureds who completed a questionnaire, and requested O.C.C.I. to visit the work site and gather information that could be compared to answers furnished on the survey.

Information was gathered on 38 insureds, one from each occupational classification included in the full study. Insured companies or individuals were selected for inclusion in the verification based on the following criteria

- Full completion of the survey --
an answer provided for every question
on the survey; and,
- Located in Tri-County or Willamette
Valley.

The first criterion was based on the need to have information on the questionnaire that could be cross-checked by D.C.C.I., while the second was designed to minimize travel and expense related to conducting the verification study.

Based on these criteria, insureds were selected at random for inclusion in the verification effort. Names of potential respondents were sent to D.C.C.I. along with survey questions to be asked. Answers of respondents were not provided. Thus the Oregon Council had no knowledge of what interviewees indicated on the questionnaire returned to the research company. The field work was carried out from April 25 to June 20, 1984.

A representative of D.C.C.I. was then sent to the work site of the insured to collect the information needed for the study. It was not possible to target the same individual who completed the questionnaire for interviewing at the work site because the survey had been filled out anonymously to fulfill the promise of confidentiality.

All data were forwarded to the research company which made the comparison between the information stated on the respondent's questionnaire and that collected at the work site by D.C.C.I.

The following questions were used for verification purposes

(Please see next page)

- Total number of years insured involved with job classification covered by the survey questionnaire previously sent (Question #3);
- Average number of workers covered under workers' compensation policy; (Question #8);
- Ownership of vehicles regularly used to transport employees to Oregon job sites (Question #14); and,
- Purchase or lease of heavy equipment during the last three years, or not (Question #15).

Overall, there was agreement in about three out of every four cases between information supplied by the respondent on the survey questionnaire and that related to O.C.C.I. during the personal visit to the insured.

For the first question verified, information was available for 36 of the 38 insureds included in the study, and in 72% of the cases there was either a one-to-one correspondence between answers obtained using the two data gathering methods or a difference of five years or less.

The table below shows the percentage of agreement for each of the four questions included in this small-scale verification study. . .

PERCENTAGE OF AGREEMENT FOR QUESTIONS IN VERIFICATION STUDY:

<u>Question Number</u> <u>(Please See Above)</u>	<u>Percentage Agreement Between</u> <u>Survey Response & O.C.C.I. Visit</u>
3	72%
8	76%
14	72%
15	75%

It is unlikely that in a verification study, such as this one, that there would be complete agreement between responses on the survey questionnaire and data collected during a personal visit.

Inconsistencies are due to

- Potential differences between the person completing the questionnaire and individual interviewed at the work site;
- Potential mis-interpretations of questions using the two questioning approaches;
- Potential mis-representations of information on either the survey questionnaire, or to the O.C.C.I. during the field visit; and/or,
- Use of untrained interviewers to gather the information needed to carry out the verification.

VICTOR ATIYEH
GOVERNOR

OFFICE OF THE GOVERNOR
STATE CAPITOL
SALEM, OREGON 97310

November 10, 1983

Dear Fellow Oregonian:

All of us share a deep concern over present economic conditions and future prospects for a healthy business climate in Oregon. In the absence of a sound economic base, thousands of Oregonians will be faced with lack of opportunity for future gainful employment. It is, therefore, vitally important that each of us do all we can to ensure that Oregon lives up to its economic potential.

As many of you know, one area of particular concern both to me and to members of the Oregon Legislative Assembly has been equity of premium associated with workers' compensation insurance in Oregon. Many hours were spent in debating this very issue during the 1983 legislative session. In the end, the Legislature, with my full concurrence, instructed the Insurance Commissioner and the State's Workers' Compensation insurance rate-making organization to oversee the conduct of an in-depth survey of Oregon employers engaged in construction activities.

The findings of this study are to be reported back to the Legislature by the Insurance Commissioner at the beginning of the 1985 session so that any remedial steps deemed necessary can be taken to ensure equity of workers' compensation insurance premium charges in Oregon.

Attached is a questionnaire that has been designed by experts in the field to provide data necessary for resolving this nagging question once and for all. As your firm has been identified as one which is engaged in construction work, you are being called on to provide us with answers to the questions. The research is being conducted by an independent research organization. They have placed a small number on your questionnaire so returns can be checked off as they are received. Your individual responses will be treated in strict confidence. No firm's individual replies will ever be singled out or will they be used for any purpose than that outlined.

Obviously, a study of this kind to be statistically valid must obtain a very high level of response. Accordingly, I would ask each of you to attach the highest priority to the timely completion and return of the enclosed questionnaire. A stamped return envelope is provided.

If there are any questions concerning the survey, please feel free to call Stanley V. Sparks, National Council on Compensation Insurance, Portland, (503) 228-4173.

Your cooperation to strengthen Oregon's economy is very much appreciated.

Sincerely,

A handwritten signature in dark ink, appearing to read "Victor Atiyeh", written over a horizontal line.

April 16, 1984

Dear Friend:

I am writing about the survey of Oregon employers engaged in construction activities that was mandated by the State Legislature, with full concurrence of the Governor. We have not yet received your completed questionnaire.

This is the first statewide survey of its kind. It will provide needed information to resolve the debate over equity of premiums associated with workers compensation insurance. Results are critical to developing a healthy business climate for Oregon.

The large number of returns is very encouraging. But, the success depends on receiving a questionnaire from everyone contacted, even firms who believe they should not be included. It is very important that we receive a response from each firm contacted. This is so all firms listed as being engaged in construction can be accounted for, no matter what their status. This is a vital necessity for the statistical validity of the research.

It is for these reasons that I am sending you a second questionnaire and postpaid return envelope. May I urge you to complete and return it as soon as possible. Even if you feel you should not be included, it is essential that we have your returned questionnaire with your present status checked off in Question #1.

No one's individual answers will ever be singled out. All replies will be kept strictly confidential by the research firm. The number on your questionnaire is solely to check returns off the mailing list as they are received.

If you have any questions, call our office collect at (503) 228-9360, and ask for Diana Persson. If not, please return your questionnaire as soon as possible, either fully completed or with the appropriate explanation checked off in Question #1.

On behalf of the Governor and State Legislature, thank you for your public spirited participation.

Most Sincerely,

Robert M. Friedman, Ph.D
Study Director

DIRECTIONS: For each question, please check the box that best fits your answer, or write in your reply. Example: [X]. If the questionnaire does not apply to you, check the appropriate reason in Question #1. All replies will be kept strictly confidential. Results for individual firms will never be singled out. Comments are welcome and can be noted in the margins of the questionnaire. When completed, please place your questionnaire into the postpaid envelope and return. THANK YOU VERY MUCH FOR YOUR TIME.

1 - It has been determined from your firm's workers' compensation policy that you employ workers who are classified as:

3724 -MILLWRIGHT WORK
Job Classification

If this is inaccurate, please check the one box that best describes your current status and return your questionnaire in the enclosed postpaid envelope. ALL OTHERS, PLEASE CONTINUE.

- a. No work bid in last twelve months
b. No construction operations in last twelve months
c. Not in business
d. No employees in this job class
e. Other (please explain):

2 - For this classification, please check yes or no according to whether each of the following types of specialty work is performed by your firm, or not.

Table with 3 columns: Question type (a-k), Yes, No. Rows include: Air conditioning machinery installation, service, repair; Erection or dismantling of machinery; Machinery service or repair; Gasoline pump and tank installation; Gasoline pump service or repair; Overhead door installation - wooden, residential or commercial; Pollution control equipment installation; Commercial or agricultural pump installation, service or repair; Commercial refrigeration machinery or equipment installation, service or repair; Platform or beam type scales installation, service or repair; Truck/Trailer refrigeration installation, service or repair.

ello, my name is _____ of J. dsley & Haslacher. I am calling to talk with _____ (INSERT NAME
 NON-RESPONDENT.) Recently, we sent your firm a questionnaire about worker's compensation
 behalf of the State of Oregon. We followed that with a telephone call to your company
 and another reminder letter. The time has now past for receipt of completed questionnaires, and
 your firm's has not been received. Every company to whom a questionnaire was sent has the right
 to refrain from completing it and sending it back. I would appreciate it if I could ask just
 a few questions so we can compare those who did respond to the survey with those who did not.
 In this way, we will know if our sample of completed questionnaires is representative of the
 companies involved in construction operations in Oregon or not. Your answers will be kept
 strictly confidential. The data will help determine the validity of the total study. May I
 please have your cooperation and ask these few questions?

- 1 - Yes
- 2 - No
- 3 - Refused/No answer/DK

First, your firm's worker's compensation policy indicates that you employ workers who are classified in class code _____, working in

Is this accurate?

- 1 - Actively in business
- 2 - No work bid in last 12 months
- 3 - No construction operations in last 12 months
- 4 - Not in business
- 5 - No employees in this job class
- 6 - Other _____

Which one of the following best describes your firm's current status?

- Would you mind just indicating the reasons why you didn't happen to complete and return the questionnaire you were sent? (PROBE FOR COMPLETE ANSWER)

- 1 - Didn't think it applied to company
- 2 - Don't have access to information
- 3 - Too long
- 4 - Never got around to it
- 5 - Never received questionnaire
- 6 - Forgot to return it
- 7 - It was a waste of time
- 8 - It was misplaced
- 9 - Other (Please explain) (DO NOT READ)

Just to clarify your reasons, which one of the following reasons that I will read best explains why you didn't happen to complete and return your questionnaire?

(READ REASONS ON LIST AT LEFT)

12 - Refused/No answer/DK

 Average No. of Workers

Could you please estimate the average number of workers per year covered under your workers' compensation policy for this class code?

 Union

 Non-Union

For a typical job during the last three years, could you tell me what percentage of employees in job class _____ have been members of a union, and what percentage have not been members of a union?

Thank you for all the questions I have. You have been very cooperative and helpful. Thank you much for your time.

MILLIMAN & ROBERTSON, INC.

EXECUTIVE SUMMARY

REVIEW OF ALTERNATIVE

PREMIUM BASES FOR

OREGON WORKERS' COMPENSATION INSURANCE

Milliman & Robertson, Inc. (M&R) was engaged by the Workers' Compensation Department of the State of Oregon to review the relative advantages and disadvantages of various alternative premium bases for workers' compensation insurance. The findings of our study are presented in this executive summary and are discussed in more detail in our full report.

SUMMARY OF RECOMMENDATIONS AND CONCLUSIONS

Based on our findings, we recommend the following course of action for the Task Force's consideration:

- 1) The National Council on Compensation Insurance (NCCI) proposal calling for continuation of the unlimited payroll premium basis with a more responsive Experience Rating Plan should be implemented immediately for the construction classes.
- 2) Steps should immediately be taken to begin collecting hours worked for the construction classes. The goals of the data collection proposal are to conclusively assess

the practical problems involved in collecting this information and to provide more complete data for quantifying premium basis alternatives in the future.

The findings upon which our recommendations are based include the following:

- 1) We agree with both NCCI and Future Costs Analysts, Inc. (FCA) that a premium inequity of some degree does exist for construction classes under the current basis for calculating Oregon workers' compensation premiums.
- 2) We do not agree that the results of the Bardsley & Haslacher, Inc. survey and the subsequent analyses by the NCCI and FCA provide conclusive evidence in support of any one alternative premium basis. This is not due to a flawed survey or faulty analyses; rather, it is the inevitable result of trying to use a necessarily limited sample to project the insurance experience of a diverse group of risks over a long period of time.
- 3) We are not aware of any estimates of the additional expense involved in compiling and verifying hours worked. In terms of the total workers' compensation premium volume for the construction classes, the long-term on-going costs may be insignificant. However, the one time transition costs may be considerable.

- 4) In our opinion, the information compiled to date is insufficient to either estimate the true equity of the system or to evaluate the implications of substantial changes in premium basis on the total rate adequacy of the workers' compensation system.

In summary, we do believe that an actuarial equity problem exists for a significant segment of the construction industry. Further, we agree that some remedial action is appropriate at this time. However, we do not believe that the interests of actuarial equity and overall rate adequacy would be served by making large-scale changes in the method of calculating workers' compensation premiums on the basis of the various analyses performed to date. In any event, we do suggest that an effort be made to begin compiling hours worked for construction employers to permit more complete analysis in the future and to answer the practical questions that have been raised.

ALTERNATIVE PREMIUM BASES

The following provides the M&R evaluation of each of the proposed premium bases. A complete discussion of the advantages and disadvantages of each proposal is included in our full report.

Unlimited Payroll (current basis)

At this time, unlimited payroll appears to be the best proxy for total hazard measurement that is readily available and verifiable. However, significant flaws do exist and should be corrected.

Limited Payroll (capped at wage equating to benefit maximum)

By ignoring the potential hazard differentials for employers paying wages in excess of the payroll limitation, this premium basis may, for certain insureds, simply correct one inequity while creating another. However, using the additional exposure data that we propose be collected, the proposal does deserve further study.

Cents-Per-Hour Worked

We believe that cents-per-hour is not sufficiently reflective of risk differentials to be used as the sole basis for workers' compensation manual premiums. However, in our opinion, a combination of cents-per-hour and payroll may eventually prove to be a viable and improved alternative, at least for the construction classes.

Unlimited Payroll with a Modified Experience Rating Plan

This proposal is a reasonable first step to correcting the apparent actuarial equity problems that have been identified. However, we do not believe that this is necessarily the best final solution. More complete data should be compiled and analyzed before a substantial deviation from existing rating practices is recommended.

Limited Payroll & Cents-Per-Hour

We believe that the loss of intuitive hazard responsiveness is a significant drawback in light of the inconclusiveness of the analyses to date and the uncertain practical problems with this option. We are concerned that if premium adjustments are made at this time, they may subsequently need to be reversed when actual insurance data is compiled.

Average Hourly Wage Adjustments Superimposed on Unlimited Payroll

Our observations on these options are the same as those for the limited payroll/cents-per-hour approach.

Number of Employees

We do not believe that this is a viable option. To date, we are not aware that this alternative has been seriously considered in Oregon.

Refinement of Construction Classifications

At this time, it does not appear that further refinement of the construction classes can be accomplished in a socially acceptable manner that significantly improves the actuarial equity of the rating structure. However, we would not eliminate this option from future consideration, since this approach to equity problems has been successfully used in other jurisdictions.

DISCUSSION OF NCCI AND FCA PROPOSALS

The NCCI has proposed the use of unlimited payroll with a modified Experience Rating Plan. FCA has put forth the limited payroll/cents-per-hour proposal and its variations. These proposals are based on numerous significant conclusions drawn from the Oregon survey. While we believe that the survey and sampling procedures used in the Oregon study are reasonable, we have some concerns about the validity of drawing conclusions based on the resulting data. There are several areas where NCCI and FCA have drawn opposing conclusions using the same data; we do not believe that we would have drawn either set of conclusions from the available data.

DISCUSSION OF THE EFFECT OF FILE & USE ON EQUITY CONSIDERATIONS

We would expect the File and Use law to help correct actuarial inequities. However, the correction will take time as carriers identify misrated market segments. The correction process will be more immediate and more complete for larger employers that command greater market attention. We believe that the Oregon rating law will take substantially longer to benefit the smaller employers.

OBSERVATIONS FROM OTHER STATES

At this time, the overwhelming majority of states are using unlimited payroll as a workers' compensation premium base. Several states have considered other bases in recent years; however, few have made significant changes because of the lack of a conclusively more equitable alternative to unlimited payroll.

The use of cents-per-hour in Washington has been the one most frequently cited as a potential prototype for Oregon. It is important to realize that this system has been in effect for many years and the problems and costs of transition to an hours worked basis are no longer well-documented. With the existence of an exclusive state fund, substantial deviations from actuarial equity will not necessarily have any impact on the coverage availability for particular classes of business. However, in a competitive environment such as Oregon, deviations from actuarial equity can create economic disincentives for private insurers to write the affected classes.

The Florida credit table implemented in 1984 is essentially the same concept as proposed by FCA for Oregon. In filing the plan, the NCCI specifically stated that this was an interim proposal pending completion of more extensive studies on the issue of premium base equity. At this time, we have no information on which to evaluate the successes or failures of the interim plan.

PREMIUM CHANGES FOR AFFECTED EMPLOYER GROUPS

The NCCI proposal will have a significantly greater impact on the medium and large employers, i.e. those whose own loss experience are given substantial credibility in the application of the Experience Rating Plan. Both the limited payroll and the FCA proposals are essentially unaffected by an insured's own loss experience and will result in substantially greater premium

increases for the small and medium sized employers. Within this category, the lower average weekly wage employers will experience the greatest increases.

SOURCES OF INFORMATION

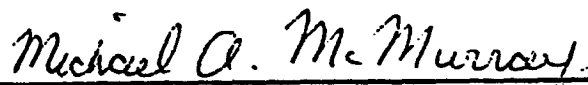

The information used for this study were provided to us by NCCI, FCA, the Governor's Task Force on Premium Equity in Workers' Compensation Insurance and the Oregon Workers' Compensation Department. We want to acknowledge all of these organizations for their cooperation in providing us with the data and responding to our questions in a timely manner.

It has been a pleasure for Milliman & Robertson, Inc. to have been of service to the State of Oregon. We are looking forward to discussing our findings in more detail.

MILLIMAN & ROBERTSON, INC.
REVIEW OF ALTERNATIVE
PREMIUM BASES FOR
OREGON WORKERS' COMPENSATION INSURANCE

Prepared for Oregon Workers' Compensation Department
Salem, Oregon

Prepared by Milliman & Robertson, Inc.

March 14, 1985

MILLIMAN & ROBERTSON, INC.
REVIEW OF ALTERNATIVE
PREMIUM BASES FOR
OREGON WORKERS' COMPENSATION INSURANCE

Milliman & Robertson, Inc. (M&R) was engaged by the Workers' Compensation Department of the State of Oregon to review the relative advantages and disadvantages of various alternatives for improving the equitability of the premium basis for workers' compensation insurance. The findings of this study are presented to the Governor's Task Force on Premium Equity in this report.

SCOPE OF STUDY

The full scope of the M&R analysis is detailed in the Statement of Work section of our contract with the State of Oregon. This can be found in Appendix A of this report. In summary, the objectives of this study were to evaluate the assumptions and procedures used by the National Council on Compensation Insurance (NCCI) and Future Cost Analysts (FCA) in the development of their respective proposals for assuring premium equity. The study was to include a discussion of the relative equity of each of the alternatives, including cents-per-hour and capped payroll. Other relevant issues, e.g. the potential impact of open competitive rating, were also to be addressed.

SUMMARY OF RECOMMENDATIONS & CONCLUSIONS

In order to put our comments and recommendations into proper perspective, an understanding of the concept of "equity" is necessary. As a point of reference, we cite the following definition taken from a text included in the syllabus of examinations for the Casualty Actuarial Society:

Actuarial equity - the concept that each person insured should pay a premium commensurate with his or her loss exposure.

The issue of "actuarial equity" has been the primary focus of our study. However, there is another concept, that of "social equity", that should at least be recognized before a final decision on a workers' compensation premium basis is made. Our review of the material previously produced on premium base equitability indicates that these two concepts have, at times, been intermingled in the discussion on premium bases. From the source cited earlier, the latter equity definition is as follows:

Social equity - the concept that each insured pay a premium commensurate with his or her ability to pay.

In light of our findings discussed below, we recommend the following course of action for consideration by the Task Force:

1) The NCCI proposal calling for continuation of the unlimited payroll premium basis with a more responsive Experience Rating Plan should be implemented immediately for the construction classes. We do not consider this approach to necessarily be a permanent or complete solution to the equity problem. Rather, we consider it a reasonable first step that is not likely to cause premium changes that are subsequently reversed.

2) Steps should immediately be taken to begin collecting hours worked for the construction classes. The goals of the data collection proposal are to conclusively assess the practical problems involved in collecting this information and to provide more complete data for quantifying future premium basis alternatives. This latter objective is particularly important to definitively evaluate the actuarial and social equity considerations of premium basis changes on the smaller, non-experience rated employers. In our opinion, the Oregon survey data for these insureds is too sparse to be conclusive, yet it is these same insureds who are most likely to experience a total premium increase as the result of a basis change.

Conversations with those familiar with the Washington system indicate that it may take 2 to 3 years to collect

the necessary information. By concentrating on the construction classifications, it may be possible to speed up the process. In any event, we believe that this proposal will not only answer the questions of practicality for construction risks, but will provide valuable insight as to the possibility of extending the approach to other workers' compensation classifications.

Our findings concerning the actuarial equity of the workers' compensation premium basis are as follows.

- 1) We agree with both NCCI and FCA that a premium inequity of some degree does exist for construction classes under the current basis for calculating Oregon workers' compensation premium. A significant percentage of high wage paying construction employers (presumably union employers) are paying a disproportionate share of the total premium for the affected classifications in relation to benefits paid.

The following table of estimated premium equity indices were derived from the Oregon survey and the three-year losses contained in the NCCI experience rating data files. These indices illustrate the potential magnitude of the equity problem:

	<u>Construction Employers</u>		
	<u>Union</u>	<u>Non-Union</u>	<u>Total</u>
High Average Weekly Wage	.81	1.26	.93
Low Average Weekly Wage	.98	1.08	1.04
Total	.90	1.12	1.00

NOTE: 1. An index less than 1.00 indicates a relative premium redundancy; an index greater than 1.00 indicates a relative deficiency.

- 2) We do not agree that the results of the Bardsley & Haslacher, Inc. survey and the subsequent analyses by the NCCI and FCA provide conclusive evidence in support of any one alternative premium basis. This is not because of a flawed survey or faulty analyses; rather, it is the inevitable result of trying to use a necessarily limited sample to project the insurance experience of a diverse group of risks over a long period of time. The extreme difference in positions taken by the NCCI and FCA, both of which reflect the input of competent actuaries, illustrates this fact.
- 3) In our opinion, the studies do provide strong evidence that cents-per-hour alone will not provide an equitable premium basis for workers' compensation insurance. Such a basis will not adequately address indemnity benefit differences that are a function of wages and, to a lesser

extent, inherent hazard differences among insureds within the same manual classification. However, the studies do indicate that cents-per-hour used in conjunction with payroll may enhance the equity of the system.

- 4) To the best of our knowledge, no definitive work has been done to determine if employee hours worked are, or can be, readily available and verifiable for Oregon employers. Based on Task Force discussions on the topic, there is reason to believe that hours worked may be easier to monitor than in the past, at least for construction industry employers. In our opinion, this point must be clarified before the usefulness of cents-per-hour as a partial premium basis can be determined. Even if an hours worked approach were to be considered theoretically superior, such a system would not be more equitable, either on a actuarial or a social basis, if it cannot be audited and isolated from insured manipulation to the same degree as the current unlimited payroll basis.

- 5) We are also not aware of any estimates of the additional expense involved in compiling and verifying hours worked. In terms of the total workers' compensation premium volume for the construction classes, the long-term ongoing cost may be insignificant. However, for individual insureds,

particularly the smaller companies, the additional expense could be significant and may adversely impact coverage availability. This particular issue is more closely related to social than to actuarial equity.

Although the long-term costs of capturing hours worked may not be prohibitive, the one-time transition costs may be considerable. Data processing systems, reporting forms, ratemaking systems, and auditing procedures would all have to be revised to implement such a change. Since many NCCI and individual insurer systems are nationwide in scope, change for one state can have an impact outside of the state as well.

- 6) In our opinion, the information compiled to date is insufficient to either gauge the inequities of the system or evaluate the implications of substantial change in premium basis on the total rate adequacy of the workers' compensation line. The results of a significant shift away from unlimited payroll under Oregon's File and Use rating law are extremely difficult to predict. However, it almost certainly will slow the re-stabilization of the workers' compensation market that has been taking place since the introduction of open rating.

In summary, we do believe that an actuarial equity problem exists for a significant segment of the construction industry. Further, we agree that some remedial action is appropriate at this time. However, we do not believe that the interests of actuarial equity and overall rate adequacy would be served by making large-scale changes in the method of calculating workers' compensation premiums on the basis of the various analyses performed to date. A clearly superior alternative to unlimited payroll has not yet been identified, although a combination of payroll and cents-per-hour does appear to have promise. In any event, we do suggest that an effort be made to begin compiling hours worked for construction employers in order to answer the practical questions that have been raised.

ALTERNATIVE PREMIUM BASES

As background information, the "premium base" is a measurement of a particular insured's exposure to loss. The premium base is multiplied by the rates contained in the workers' compensation manual to derive the total manual premium for the insured. The total premium collected at the beginning of the policy term is the manual premium adjusted for any experience rating modifications, expense constant and minimum premium considerations, and other rating variables that might apply. There can be further adjustments in the net cost of workers' compensation at the end of the policy term due to the application

of retrospective rating plans and/or dividend payments and exposure record audits.

To put the premium base controversy into perspective, it is important to note that the issue was first addressed in writing by the actuarial profession in the 1929 Proceedings of the Casualty Actuarial Society in an article titled "Notes on Exposure and Premium Bases". The author, Paul Dorweiler, and his reviewers entered into a discussion of the merits and drawbacks of using payroll as a premium base, with emphasis on the equity of the approach for the skilled mechanical and building trades. The arguments presented were essentially the same as those that evolved from the Oregon study, with no resolution reached. Obviously, this is not a new or quickly resolved issue.

The following is a discussion of the principal advantages and disadvantages of the 8 premium basis alternatives that have been proposed at various times for construction workers in Oregon. The list of advantages and disadvantages is not exhaustive; instead, we have concentrated on the primary characteristics which, in our opinion, affect the relative actuarial equity of each option. For a more exhaustive listing of the perceived strengths and weaknesses, please refer to Appendix B.

We emphasize that the individual benefits and drawbacks discussed

below do not necessarily reflect the opinions of M&R. They do reflect our judgment concerning the most significant points that have been raised at various times. The M&R opinion regarding the relative merits of each is presented in the M&R evaluation.

Unlimited Payroll (current basis)

To the extent that the combination of wage levels and hours worked are a reasonable proxy for exposure, the foremost advantage to this premium basis is that it is reflective of the total hazard (i.e. claim frequency, duration of injury and average benefits) presented by an insured. A further advantage that should not be taken lightly is that unlimited payroll data is readily available and auditable for every insured.

The most significant disadvantage is that differences in average weekly wages that are not always related to variances in occupational hazard (e.g. union and non-union employers competing for the same contracts) can result in apparent actuarial inequities in the rating system.

M&R EVALUATION: At this time, unlimited payroll appears to be the best proxy for total hazard measurement that is readily available and verifiable. However, significant flaws do exist and should be corrected.

Limited Payroll (capped at wage equating to benefit maximum)

The principal advantage to this basis is that it is reflective of the total hazard for employees below the wage qualifying for the maximum benefit. It does, to an extent, temper distortions in the rating system attributable to non-hazard related average wage variations.

The primary disadvantage is that it ignores occupational claim frequency and injury duration characteristics that may be reflected in wage levels higher than the established maximum. There is concern that a capped payroll may be more subject to insured manipulation, although there is a historical precedent for payroll limitation.

M&R EVALUATION: By ignoring the potential hazard differentials for employers paying wages in excess of the payroll limitation, this premium basis may, for certain insureds, simply correct one inequity while creating another. However, the proposal does deserve further study using the additional exposure data that we propose be captured.

Cents-Per-Hour Worked

The advantage of this approach is that it circumvents the problem of average wage variations within a class which are not hazard related. Also, there is an intuitive correlation

between claim frequency and hours worked.

The critical disadvantage to cents-per-hour is that it ignores potential differences in the injury duration and severity characteristics among insureds within a classification. There are also problems concerning the data availability and verifiability, the ramifications on the workers' compensation ratemaking process, and the response of the insurance carriers under the File and Use law. Any actual or perceived imbalance in the overall rate adequacy resulting from a change based on inconclusive information could seriously impair market availability and stability.

M&R EVALUATION: We believe that cents-per-hour is not sufficiently reflective of risk differentials to be used as the sole basis for workers' compensation manual premiums. However, in our opinion, a combination of cents-per-hour and payroll may eventually prove to be a viable and improved alternative, at least for the construction classes.

Unlimited Payroll with a Modified Experience Rating Plan

The greatest advantage to this proposal is that it does not reduce the overall responsiveness of the underlying premium basis, but does significantly address the observed inequities for large, high wage paying employers. It can be implemented

immediately without creating other unintended actuarial equity problems.

The most significant disadvantage is that it does nothing to reduce premium inequities that may exist between the small or average sized high and low wage paying employers. Further, it may be overly responsive to fortuitous large claims for these employers.

M&R EVALUATION: This proposal is a reasonable first step to correcting the apparent actuarial equity problems that have been identified. However, we do not believe that this is necessarily the best final solution. More complete data should be compiled and analyzed before a substantial deviation from existing rating practices is recommended.

Limited Payroll & Cents-Per-Hour

This approach would involve using the capped payroll discussed above for indemnity benefits and cents-per-hour for medical. The key advantage is that it significantly reduces the premium distortions due to average weekly wage differences that may be unrelated to hazard. Further, it does provide a limited proxy for recognizing potential claim frequency, duration and average indemnity benefit characteristics among risks in the same class.

The principle disadvantages are the practical problems discussed above for the two bases separately and the potential loss of hazard responsiveness for certain high wage paying employers. Those insureds most likely to pay higher total premiums under this proposal are the small, low wage paying employers for which the Oregon survey results are the least conclusive. These are the insureds who generally do not have experience rating or other plans available to them to temper manual rate inequities.

M&R EVALUATION: We believe that the loss of intuitive hazard responsiveness is a significant drawback in light of the inconclusiveness of the analyses to date and the uncertain practical problems with this option. We are concerned that if premium adjustments are made at this time, they may subsequently need to be reversed when actual insurance data is compiled.

Average Hourly Wage Adjustments Superimposed on Unlimited Payroll

FCA presented two possible options for implementing the concept of limited payroll and cents-per-hour while maintaining unlimited payroll. The options include:

- a supplemental premium discount table and

- a supplemental premium discount and surcharge table.

The main advantages and disadvantages are essentially the same as for the limited payroll/cents-per-hour proposal. One additional advantage would be that the basic concept of an inflation sensitive exposure base (i.e. payroll), which has helped to keep wide swings in the indicated manual rates to a minimum, would be retained in the overall ratemaking process. A further disadvantage would be the necessity of maintaining three exposure measures for each insured in order to calculate both manual premium and the supplemental adjustments.

M&R EVALUATION: Our observations on these options are the same as those for the limited payroll/cents-per-hour approach.

Number of Employees

The advantages of number of employees as a premium basis are its inherent simplicity and relative ease of verification.

Further, there are no potential premium distortions due to average weekly wage variations.

A major disadvantage to this approach is that the number of employees is generally not a reasonable indicator of claim

frequency, injury duration or average benefit levels payable.

M&R EVALUATION: We do not believe that this is a viable option. To date, we are not aware that this alternative has been seriously considered in Oregon.

Refinement of Construction Classifications

The most significant advantage to this approach is that it goes to the heart of the problem: insureds within a particular manual class have distinctly different hazard potential as related to payroll. Segregation of such risks would not disrupt the current ratemaking and rating systems and there is certainly precedent for creating specialized classes.

The critical disadvantage is that such sub-classes have not yet been defined in a clear cut manner that is not susceptible to field manipulation. Also, the actuarial credibility of the data compiled for sub-classes may be too limited to correct the perceived problem.

M&R EVALUATION: At this time, it does not appear that further refinement of the construction classes can be accomplished in a socially acceptable manner that significantly improves the actuarial equity of the rating

structure. However, we would not eliminate this option from future consideration since this approach to equity problems has been successfully used in other jurisdictions.

REVIEW OF THE NCCI AND FCA ANALYSES

The NCCI solution to the inequities in the workers' compensation rates is a modification of the Experience Rating Plan for construction employers. This modification consists of two components: (a) an additional credit/surcharge based on expected losses and the ratio of actual losses to expected losses; and (b) an increase of 15 points in the "D ratios" for each classification. As discussed above, the credit formula will correct a portion of any inequities in the premiums charged to experience rated insureds. The effect of the increase in the D ratio is to further increase the amount of reliance placed on an insured's own experience in developing total workers' compensation premium. A complete discussion of this proposal is presented in Appendix C.

FCA proposes that premiums for medical benefits and low maximum benefits be based on hours worked. The remainder of the indemnity benefits would be based on limited payroll. This proposal is discussed in more detail in Appendix D. Underlying these premium bases is the assumption that higher wages do not reflect higher hazard as measured by frequency or duration of

injuries.

We believe that the survey and sampling procedures used by the NCCI in the Oregon Study were reasonable. However, we have some concerns about the validity of drawing conclusions based on the resulting data. Our major concerns (discussed in more detail in Appendices C and D) include the potential for: (1) biases in the data introduced by the elimination of insureds for practical reasons; (2) biases in the premium and loss data due to the immaturity of the data; and (3) biases introduced by the selection of the measures of inequity. There are several areas, for instance, the relationship between medical severity and wages, where the NCCI and FCA have drawn opposing conclusions based on the same data; we do not believe that we would have drawn either conclusion from the available data.

To illustrate the inconclusiveness of the data compiled to date, we have included, as Exhibit 1, a comparison of the "premium equity indices" resulting from the various proposals under consideration. The data used for this comparison are the NCCI calculated three-year aggregate loss ratios to standard premium for the identified experience rated employers. Based on our observations of the survey experience, we believe that this may be the best data compiled for the sample for drawing conclusions.

In their evaluation of the results, the NCCI concentrated on the relationship between union and non-union employers. In fact, the NCCI proposal does appear to address this discrepancy better than the other proposals. On the other hand, FCA concentrated on the discrepancy between high and low average wage payers. From that perspective, the FCA proposal appears more effective.

If one were to evaluate the proposals by minimizing the average overall "inequity", giving equal weights to each union status/wage level cell, the NCCI proposal would appear to be slightly preferable. However, with the data limitations discussed earlier, we cannot attach much significance to such a measurement.

DISCUSSION OF THE EFFECT OF FILE & USE ON EQUITY CONSIDERATIONS

In a study performed for the California Assembly in 1982, open rating for workers' compensation was presented as one possible long-term solution to the classification equity problems that may exist for this line of coverage. The point was that if the insurance industry was substantially free to react, market forces would identify and compete for those workers' compensation insureds that are inaccurately priced in terms of inherent risk. For example, if high wage paying union employers were consistently overcharged for coverage, this class of risk would present a potential "pocket of profit" for insurers. Once this

fact was recognized, there would be intense competition for this segment of the market, which eventually would result in a lower premium level for the class. In other words, market forces operating in an open rating environment would correct any existing price inequities.

With its File and Use statute for workers' compensation rates, Oregon comes closer to true open rating for the line than most other states. Therefore, the economic scenario discussed above is more likely to be realized in Oregon than in most other jurisdictions at this time. Although we do not have sufficient expertise in economic theory to discuss all aspects of open rating in depth, we do offer the following observations of how the issue of workers' compensation premium equity might be affected by the state's File and Use law.

- 1) Since its enactment in 1982, Oregon carriers have used the statute to create a broad spectrum of overall rate levels. In this respect, the File and Use law is functioning as planned. However, most insurers are still highly dependent on NCCI data and expertise to determine how rate levels should be spread among individual classes. This is not necessarily due to a failure in the open rating system. Instead, most companies simply do not yet have the amount of data necessary to deviate from the implied

NCCI class relativities on an actuarially sound basis. We expect the insurance carriers to deviate from the NCCI classification relativities more frequently in the future when more internal information is compiled.

- 2) On a related point, insurance carriers are still becoming accustomed to a workers' compensation system operating in a more competitive environment. We believe that many carriers are still more concerned with the practical operations issues and have not yet had the opportunity to make full use of this new pricing flexibility. Unfavorable underwriting results in recent years for the workers' compensation line in Oregon may also have reduced the amount of classification rating refinement that has taken place.

- 3) Even before the advent of File and Use, the higher aggregate payroll employers had more of a competitive advantage than the smaller employers. This is not due to any actuarial inequities; rather, it is due to the attractiveness of the size of premium generated by the larger employers and the fact that they are more likely to qualify for supplemental rating plans (e.g. experience rating, retrospective rating, dividend plans, et al) that can tailor costs more closely to the actual experience of

the specific insured. The qualification standards for such plans are generally based on actuarial credibility criteria; i.e. the statistical sufficiency of one's own experience to be used in insurance pricing.

Under File and Use, we expect this to continue. This will result in a substantial correction in any manual rate inequities that exist for the larger high wage paying construction employers. However, the small and average sized, high wage paying employers are less likely to benefit from this process.

In summary, we would expect the File and Use law to help correct actuarial inequities. However, the correction will take time as carriers identify misrated market segments. The correction process will be more immediate and more complete for larger employers that command greater market attention. We do believe that Oregon's rating law will take substantially longer to benefit the smaller employers.

OBSERVATIONS FROM OTHER STATES

At this time, the overwhelming majority of states are using unlimited payroll as a workers' compensation premium base. Although several states have considered other bases in recent years, few have made significant changes. For the most part, the

decisions not to change were made because a conclusively more equitable alternative that was both readily available and verifiable could not be identified. However, we are not aware of any state that has undertaken an analysis as complete as was performed in Oregon.

The following is a list of states that have implemented, or will soon implement, an alternative to unlimited payroll:

- Washington: cents-per-hour, since 1933;
- Nevada: limited payroll;
- Florida: limited payroll/cents-per-hour credit table for construction classes implemented in 1984; and
- Maryland: Experience Rating Plan modification proposal filed by NCCI in January, 1985.

The Washington situation has been the one most frequently cited as a potential prototype for Oregon. In fact, Washington apparently has been able to compile both hours worked and payroll for insureds with satisfactory results. However, it is important to realize that this system has been in effect for many years and the problems and costs of transition to an hours worked basis are no longer well documented.

Another point to consider in attempting to draw analogies with Washington is the particular delivery system that each state has

for workers' compensation coverage. Unlike Oregon, Washington employers only have a choice between self-insuring and obtaining coverage from an exclusive state fund. Private commercial carriers do not write workers' compensation insurance in the state.

With an exclusive state fund, substantial deviations from actuarial equity will not necessarily have any impact on the coverage availability for particular classes of business. However, in a competitive environment, deviations from actuarial equity can create economic disincentives for private insurers to write the affected classes. Therefore, a premium basis that appears to function satisfactorily in Washington may not work at all in Oregon. Interestingly, Washington has studied the possible transition to a payroll basis of some type in recent years. We understand that such a change has not taken place due primarily to social considerations, not issues of actuarial equity.

The workers' compensation delivery system in Nevada (i.e. self-insurance or an exclusive state fund) is quite similar to that of Washington. Therefore, any analogies drawn between Nevada's use of a limited payroll basis and the expected results of using a similar base in Oregon are subject to the same constraints as discussed above. However, we reiterate that prior

to the 1970's payroll limitations were commonplace in competitive environments. This does indicate that such a concept is at least feasible.

The Florida credit table implemented in 1984 is essentially the same concept as proposed by FCA for Oregon. Credits are applied to the standard premium for construction classifications based on average hourly wages. The credits range from 0% for hourly wages of \$9.99 or lower to 25% for wages in excess of \$17.50. Because this is a credit only table, a net loss in total premium volume would be realized. To offset this loss, a manual rate increase, averaging 4% for the construction classes, was simultaneously implemented. However, the actual manual rate increase by individual class varied between 0% and 33%.

In filing the Florida Contracting Classification Premium Adjustment Plan, the NCCI specifically stated that this was an interim proposal pending completion of more extensive studies (presumably the Oregon survey) on the issue of premium base equity. At this time, we have no information on which to evaluate the successes or failures of the interim plan.

On January 18, 1985, the NCCI filed with the State of Maryland essentially the same proposal as they set forth for Oregon. Entitled the Loss Ratio Adjustment Program, LRAP includes the

same supplemental Experience Rating Plan credit/surcharge table, applicable just to construction classifications, as developed for Oregon. However, the "D ratio" increase proposed for the construction classes was only 5 points compared to the 15 point increase suggested for Oregon. Both "D ratio" changes will tend to increase the amount of experience rating modification for construction insureds, although the Maryland approach will temper the impact that volatile actual losses may have on the standard premium.

PREMIUM CHANGES FOR AFFECTED EMPLOYER GROUPS

As part of our review we have attempted to quantify the possible impact that the various premium basis alternatives could have on the affected construction employer groups. As discussed above, one of our main concerns about any dramatic change in the exposure basis under the current File and Use environment is that the ultimate net premium level adjustments are very uncertain. However, we do offer the following information as a rough gauge of the amount of change that could be expected.

In evaluating these estimates, several points should be considered. First, there will be many exceptions to the general conclusions drawn. As examples of the levels of change that might be expected, we have relied on the premium calculations made by the NCCI for "typical" insureds. The results can and

will vary by insured and by insurer. Second, the actual premium depends on the specific parameters of each proposal. We would fully expect some changes in the parameters before they are finalized for an actual rate filing. Third, a rate increase, per se, for some insureds is not necessarily "bad". When considering rating modifications in the interests of actuarial equity, by definition some insureds will have increases while others will have decreases. This is the inevitable result of correcting inappropriate subsidies within the rating structure.

The NCCI prepared standard premium comparisons for four scenarios: the current system, the indexed limited payroll proposal, the FCA limited payroll/cents-per-hour approach, and the NCCI Experience Rating Plan modification proposal. The following are the observations by type of construction employer group.

Table of Sampled Oregon Construction Employer
Standard Premium Changes

	<u>NCCI Proposal</u>		<u>Indexed Limited Payroll</u>		<u>FCA Proposal</u>	
	<u>#</u>	<u>Range</u>	<u>#</u>	<u>Range</u>	<u>#</u>	<u>Range</u>
Small Employer						
<u>High Losses</u>						
(3 Insureds)						
Increases	1	1%	2	3%-10%	1	45%
Decreases	--	--	1	40%	2	2%-43%
<u>Low Losses</u>						
(5 Insureds)						
Increases	--	--	4	6%-14%	4	4%-22%
Decreases	3	5%-14%	1	12%	1	17%
Medium Employer						
<u>High Losses</u>						
(1 Insured)						
Increases	1	6%	1	11%	1	18%
Decreases	--	--	--	--	--	--
<u>Low Losses</u>						
(4 Insureds)						
Increases	--	--	3	10%-14%	3	7%-26%
Decreases	4	16%-40%	1	9%	1	15%
Large Employer						
<u>High Losses</u>						
(2 Insureds)						
Increases	2	17%-23%	1	7%	--	--
Decreases	--	--	1	24%	2	1%-28%
<u>Low Losses</u>						
(3 Insureds)						
Increases	--	--	3	2%-5%	2	4%
Decreases	3	9%-26%	--	--	1	4

NOTES: 1. Employer size is determined as follows:

	<u>Current Standard Premium</u>
Small	Less than \$3,000
Medium	\$3,001 to \$50,000
Large	Greater than \$50,000

2. Low loss employers are identified as those with actual losses less than expected losses; high loss employers are those with actual losses greater than the expected levels.

No comparison was done for actual insureds with a cents-per-hour only premium basis. However, we would anticipate that a cents-per-hour approach would affect the same category of insureds as the FCA proposal. We would expect that the range of premium increases and decreases would be more exaggerated with an hours worked base.

In summary, the NCCI proposal will have a significantly greater impact on the medium and large employers, i.e. those whose own loss experience is given substantial credibility in the application of the Experience Rating Plan. Both the limited payroll and the FCA proposals are essentially unaffected by an insured's own loss experience and will result in substantially greater premium increases for the small and medium sized employers. Within this category, the lower average weekly wage employers will experience the greatest increases.

SOURCES OF INFORMATION

The information used for this report were provided to us by NCCI, FCA, the Governor's Task Force on Premium Equity in Workers' Compensation Insurance and the Oregon Workers' Compensation Department. We have reconciled the information provided by the various organizations to the extent possible within the limited time available. We have discussed any significant differences in

this report.

We would like to extend our appreciation to all of these organizations for their timely response to our questions and requests for further information.

NOTES:

1. Indices based on 3 year loss ratios to standard earned premium.
2. An index less than 1.00 indicates a relative premium redundancy; an index greater than 1.00 indicates a relative deficiency.

APPENDIX A

Statement of Work

AMENDMENT TO PERSONAL SERVICES CONTRACT

1. This contract is between the State of Oregon acting by and through its Workers' Compensation Department hereafter called the Department, and Milliman and Robertson hereafter called the Contractor.

2. Addendum No. 1 to original contract number 229.

3. The contract entered into on February 15, 1985, between the Department and contractor shall be amended as follows:

Paragraph 1. Statement of Work is replaced with the following:

a. Contractor agrees to accomplish the following work under this contract:

- 1) Analyze the data collected and procedures used by the National Council on Compensation Insurance (NCCI) for determining a more equitable basis for Workers' Compensation premiums in the construction industry in Oregon. The objective will be to evaluate the validity of the assumptions and procedures used by the NCCI to reach their previously published conclusions.
- 2) Critique the proposed solutions recommended by the NCCI in the "Study of Premium Equity by Employer Groups" and by Future Cost Analysts, Inc. in "An Equitable Basis for Workers' Compensation Premiums." The critique will include identification of the advantages and disadvantages of each alternative that has been considered, including the current system.
- 3) Review the alternatives to total payroll premium basis, including, but not limited to, cents-per-hour and capped payroll.
- 4) Discuss the possible impact of File and Use (open competitive rating) on the alternative premium bases.
- 5) Discuss the relative equity of each of the alternative premium bases and recommend the most equitable alternatives.
- 6) Review the results from other states that have implemented or considered alternatives to the current system.
- 7) Prepare a formal report on the results of the evaluation and findings for items 1-6. The report will include an explanation of the methodology used and assumptions made to arrive at the conclusions.

- 8) Present findings to the Governor's Task Force on Premium Equity and the Joint Senate and House Labor Committees.
- 9) Contractor agrees to the following delivery schedule for the work mentioned in (1)(a): March 15, 1985.

4. In performing the above, it is understood and agreed that all other terms and conditions of the original contract are still in effect.

Dated this 26 day of February, 1985.

APPENDIX B

Detailed Listing of the Advantages and Disadvantages
of Selected Premium Basis Alternatives

State of Oregon - Workers' Compensation Department

UNLIMITED PAYROLL

ADVANTAGES

1. The exposure base is readily available and verifiable.
2. It reflects the total exposed risk.
3. It is more responsive to the economic climate than the cents-per-hour proposal; ergo, less dramatic rate changes and more predictability for budgeting.
4. It avoids the arbitrary and potentially inequitable "head" count syndrome that limitations on payroll can induce.
5. It gives the opportunity for maximum front-end rate responsiveness to economic changes.
6. It provides less opportunity for manipulation by large insureds; ergo, more equity for all insureds.
7. It produces lower front-end premiums for small insureds who do not have an experience rating plan safety valve.
8. Overall, this proposal will entail less of a record keeping expense.

State of Oregon - Workers' Compensation Department

UNLIMITED PAYROLL

DISADVANTAGES

1. Variations in average weekly wages will produce inequitable premiums.
2. There will be no reflection of the maximum weekly benefit in the rates.
3. Frequency should be more directly related to hours worked.
4. The duration of each injury should be more directly related to hours worked.
5. The duration of each injury should not vary within each class.
6. Medical and low-maximum or lump-sum indemnity benefits should be the same for all workers in a class.
7. The Experience Rating Plan does little to temper inequities for the construction industry.

State of Oregon - Workers' Compensation Department

UNLIMITED PAYROLL

REJOINDERS TO DISADVANTAGES

1a. Under normal conditions, competitive forces lead to uniformity of average weekly wages for specific work activity.

b. There will always be exceptions, but the proposal must fit the typical situation.

c. This proposal is tempered by application of the Experience Rating Plan. This avoids measuring hazard by "head" count.

2a. The proposal must recognize that premium is based on both frequency and severity.

b. Also, total payroll addresses, indirectly, the potential seriousness of injury.

c. The same logic that would say "cap" exposure due to indemnity benefit "cap", would imply an unlimited exposure basis for unlimited medical benefits.

3. There is no firm statistical basis to support the contention that medical is not correlated with payroll.

State of Oregon - Workers' Compensation Department

NCCI PROPOSAL

UNLIMITED PAYROLL WITH MODIFIED EXPERIENCE RATING PLAN

ADVANTAGES

1. This proposal maintains the advantages of unlimited payroll.
2. It addresses, at least partially, the particular problem faced by the construction industry, without disrupting other classes.
3. It could serve as a model for other problem classes.
4. It produces nominal rate dislocations.
5. It requires minimal additional expense.

DISADVANTAGES

1. One large claim can cause substantial swings in experience rating modifications.
2. Swings would hurt smaller experience rated employers more.
- 3a. Based on actuarial theory, wage differentials are too large to be corrected by the experience rating plan, even as modified.
b. Also based on actuarial theory, the average construction company does not have enough claims to be credible. This observation concentrates on the smallest employers.
4. The NCCI will not apply this proposal outside of the construction industry; ergo, NCCI does not think it is desirable for other industries.
5. This proposal does not completely eliminate inequities.

REJOINDERS TO DISADVANTAGES

1. This proposal relates directly to actual loss experience.
2. No "loss free" risks are required to have a rate increase.

State of Oregon - Workers' Compensation Department

INDEXED LIMITED PAYROLL

ADVANTAGES

1. The Indexed Limited Payroll proposal addresses maximum weekly benefits.
2. It recognizes variations in average weekly wages.
3. If indexed adequately, this proposal measures exposure better than the cents-per-hour proposal.
4. With some additional cost, Indexed Limited Payroll will be readily available and verifiable.
5. This proposal gives some potential relief to high-wage payers who do not qualify for a significant experience rating modification.

State of Oregon - Workers' Compensation Department

INDEXED LIMITED PAYROLL

DISADVANTAGES

1. Indexed Limited Payroll requires additional record keeping.
2. It produces less of a measure of total exposure.
3. It can degenerate into a "head" count.
4. It can be more inequitable to small insureds who do not have the Experience Rating Plan as a safety valve.
5. It requires higher front-end rates which adversely impact low-wage payers or smaller insureds.
6. This proposal redistributes premium from high-wage payers to low-wage payers.
7. It is subject to some manipulation, which is not fair to insureds who do abide by the premium reporting rules.
8. It disregards the cost of additional medical benefits.
9. It also disregards the loss experience of the individual insureds.
10. "Loss-free" insureds would pay more premiums.

REJOINDERS TO DISADVANTAGES

1. The expense of the additional record keeping is relatively small.
2. If indexed adequately, the payroll limitation still measures the total exposure for most insureds.

State of Oregon - Workers' Compensation Department

CENTS-PER-HOUR WORKED

ADVANTAGES

1. The cents-per-hour proposal circumvents the problem of varying average weekly wages for some classes of hazards.
2. This proposal reflects size of employer and length of time on a job.
3. The most reasonable assumption is that employers in the same class will have the same number of claims per hour worked.
4. For medical, low-maximum and lump-sum indemnity, costs should only vary with the frequency, which varies with hours worked.
5. There is no relationship between rehabilitation costs and wages.
6. In Oregon's study, over 40% of workers earned more wages than were necessary to qualify for maximum benefits.

State of Oregon - Workers' Compensation Department

CENTS-PER-HOUR WORKED

DISADVANTAGES

1. Hours worked are not universally collected, available or verifiable. It would not be fair to require those who would report honestly to subsidize the insurance costs of those who would not.
2. The implementation of this proposal requires additional expense.
3. Data would need to be collected for several years before it could be of value in pricing.
4. Activities that are more strenuous or hazardous may have different frequencies per hour worked.
5. Cents-per-hour worked ignores urbanization, availability and utilization phenomena affecting medical costs.
6. The Experience Rating Plan essentially corrects for inequities anyway.
7. This proposal is not as responsive to the economic climate as other proposals.
8. It would have the greatest potential negative impact on smaller (non-experience rated) employers.
9. Changing the data base to cents-per-hour will produce an unknown impact on rate and overall premium levels.
10. Implementation of this proposal will further exasperate uncertainty caused by the File and Use system.
11. The relationship between rate levels and wages is ignored.

State of Oregon - Workers' Compensation Department

CENTS-PER-HOUR WORKED

REJOINDERS TO DISADVANTAGES

1. Some less hazardous jobs (e.g. foreman) can actually have higher payrolls.
2. An Experience Rating Plan does nothing for non-experience rated risks and little for smaller qualifying employers.
3. Oregon's study "disproved" the urbanization, availability and utilization theories for medical benefits.
4. The greatest negative impact is simply a correction of past rating inequities.
5. It is unlikely that necessary data is not readily available.
6. The additional expense of implementing this proposal is nominal and justifiable.
7. This proposal assumes that hazard differences are adequately handled by the classification system.

State of Oregon - Workers' Compensation Department

FCA PROPOSAL

LIMITED PAYROLL / CENTS-PER-HOUR WORKED

ADVANTAGES

1. The FCA proposal removes any possibility of average weekly wage variance distortions affecting medical and low-maximum indemnity.
2. This proposal maintains a relationship to wages for those indemnity benefits affected by wages.
3. It has the same advantages as both the limited payroll proposal and the cents-per-hour worked proposal.

DISADVANTAGES

1. Implementation of this proposal would present additional cost and verifiability problems.
2. This proposal would increase premiums for "loss-free" small insureds with low wages.
3. It ignores certain hazard differences affecting medical and, to a lesser extent, indemnity benefits.
4. It is not as responsive to economic climate as other methods would be.
5. Under this proposal, the system is subject to greater manipulation.
6. Implementation of this proposal will further exasperate uncertainty caused by the File and Use system.

REJOINDERS TO DISADVANTAGES

1. This proposal has the same features as both the limited payroll and the cents-per-hour worked proposals.

State of Oregon - Workers' Compensation Department

FCA PROPOSAL

CREDIT TABLE OR CREDIT/SURCHARGE TABLE

BASED ON AVERAGE HOURLY WAGES

ADVANTAGES

1. This proposal has the same advantages as the combination limited payroll/cents-per-hour worked proposal.
2. It also maintains the basic concept of unlimited payroll.

DISADVANTAGES

1a. Implementation of a "credit-only" proposal would create a substantial increase in manual rates, resulting in collected premium increases for small employers.

b. Although base rates could be kept close to their current levels with a credit/surcharge table, collected premiums for small employers would probably go up.

2. This proposal would require regular updating of the tables.
3. It also encompasses the same disadvantages as the combination limited payroll/cents-per-hour worked proposal.

State of Oregon - Workers' Compensation Department

NUMBER OF EMPLOYEES

ADVANTAGES

1. The number of employees method is easy to comprehend and implement.
2. There are no average weekly wage distortions.

DISADVANTAGES

1. The number of employees insured does not reflect the amount of time each employee is exposed to any potential hazard.
2. The number of employees insured also does not reflect the types of injuries suffered and thus no estimation of the benefit or the duration of the injury can be made.

EXPERIENCE RATING PLAN

I. INTRODUCTION

Experience Rating Plan is intended to increase the accuracy of the premium calculation system by incorporating the recent experience of an insured as an enhancement to the classification process. The NCCI Experience Rating Plan is a prospective rating plan; i.e., it is used to determine the rate for a policy period prior to the availability of actual claim experience for that period. The Experience Rating Plan provides a refinement to the class rates which are determined by the type of business, in an effort to assess the appropriate premium rate for a particular insured.

The Experience Rating Plan results in an experience modification factor which is applied to the manual rate in order to determine the rate for a particular insured.

The fundamental technique in experience rating is to compare the historical experience of the insured with the expected experience (based on the insured's class) in order to adjust the price of the insurance provided. The experience rating plan is intended to use information contained in the historical experience of the insured to the extent it is a relevant predictor of future experience.

The impact of random variation in claim experience is reduced through the use of credibility weighting. The experience rating formula assigns a credibility (or weight) to the actual historical losses of the insured. This credibility represents its predictive power relative to that of the expected losses based on the manual rate for the insured's class. The complement of the credibility (the remaining weight) is assigned to the expected losses.

NCCI has filed the Revised Experience Rating Plan (Item E-1235) in most of the jurisdictions where it is the licensed rating bureau. In the remainder of this report, we will refer to the Revised Experience Rating Plan as RERP, and the Prior Experience Rating Plan as PERP. Where it is not important to distinguish between RERP and PERP, we will refer to the Experience Rating Plan as ERP.

The objectives of this report are to describe and evaluate the current NCCI Experience Rating Plan.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

II. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

The following are our conclusions about the NCCI experience rating plan. Direct reference is made to questions the NAIC asked us to address in this study.

A. Procedures and Formulas Used by NCCI

Objective (7a): Is the NCCI's Revised Experience Rating Plan (RERP) actuarially sound? What improvements could be made in the plan?

In responding to this objective (7a), we examined the following issues:

1. Accuracy of the RERP
2. **Credibility:** Credibility refers to the weight given to each risk's actual losses in the experience modification formula. We compare NCCI credibilities against optimum credibilities produced through regression formulas.
3. **Split Point:** The NCCI experience rating plan splits a risk's actual losses into primary and excess components. The primary loss in the RERP is the first \$5,000 of each loss and the excess is the balance. We examine whether the plan could be improved by increasing or decreasing the split point.
4. **Balance of plan:** The balance of the experience rating plan refers to whether or not the average experience modification factor is 1.0. We examine whether the NCCI plan is balanced, and if not, whether it should be.
5. **Administration:** We review the internal methods and procedures of NCCI to evaluate whether the experience rating plan is properly administered.

Each of these is discussed in more detail below.

1. Accuracy of the RERP

We have evaluated the accuracy of the Revised Experience Rating Plan, and find it to be more accurate, on average, than the Prior Experience Rating Plan it replaces.

EXPERIENCE RATING PLAN

In Section III.G. we discuss an alternate experience rating formula which is a combination of both a formula used by the Insurance Services Office and the current NCCI approach. The alternate formula (discussed below) would adjust expected excess losses by an experience modification factor based on primary losses, whereas the current NCCI expected excess losses are not affected by the actual primary losses.

2. Credibility

An analysis of the credibility formulas currently used by NCCI is included in Section V. We found that historical primary losses were predictive of both future primary losses and future excess losses. As a result, under the RERP, primary credibilities are above the optimum level needed to predict primary losses alone. This increase is reasonable under the constraints of the RERP, since there is no other way to reflect the ability of primary losses to predict future excess losses given the structure of the RERP formula.

We have developed an Alternate Experience Rating Formula which directly incorporates primary losses as a predictor of future excess losses. Under this formula the primary experience modification would be used to adjust the expected excess losses before the application of excess credibility. This procedure would result in an experience modification to expected excess losses (based on primary losses) even if the credibility of actual excess losses were zero.

We believe that primary and excess losses are correlated. As a result, we believe that the Alternate formula can be expected to produce more accurate results than the RERP (or a version of the RERP in which the parameters have been optimized as in the Alternate formula). However, the degree of improvement is not clear. We recommend that further testing be done by NCCI using more states and more time periods to evaluate the degree of improvement produced by the Alternate formula. If the degree of improvement is found to be substantial, then we would recommend implementing the Alternate formula as soon as is practical. If the improvement is found to be minor, then the practical difficulties involved in implementing a change in the formula make it appropriate to postpone implementation until such time as other significant changes are being implemented, or possibly to forego implementation altogether. This will be a matter of professional judgment.

It should be noted that a change to the Alternate formula should not be expected to affect the total premium adequacy for all risks combined in a given state.

EXPERIENCE RATING PLAN

In addition to developing the Alternate formula, we have developed a technique for estimating the credibility parameters which best fit a given set of data. If NCCI does replace the RERP with the Alternate formula, we recommend that they refine the parameters by applying that technique to countrywide data. It should be noted that adjustments to the optimized parameters may be appropriate for practical purposes.

3. Split Point

The equity of a split point is evaluated in Section VII.

Use of a split point increases the accuracy, and therefore, the equity of an experience rating plan. The predictive value of prior experience is lower for extremely high loss amounts than for moderate to low loss amounts. As a result, without a split point, an unusually large single loss would produce a larger debit than is warranted, while unusually low loss amounts would produce a smaller credit than is warranted.

The current split point of \$5,000 represents a reasonable compromise between minimizing "linearization error" and maximizing the amount of data classified as primary. Significantly increasing or decreasing the split point results in a deterioration of the performance of the plan as measured by both the modified Loss Ratio and the Mean Squared Error tests.

4. Balance of plan

Recommendations for improvements in ELR and D-ratio calculations are given in Section IV which, if implemented, should produce reasonably balanced results for the plan. We conclude that if these recommended changes are implemented and if ELR's are updated on a regular basis, any persistent off-balance that results will be due to real cost differences between experience rated risks and the average of all risks. We believe that if such differences are manifested in the experience modification factors, they should be eliminated through adjustments in the manual rate structure, to the extent practical. To the extent that this is not practical, they should be allowed (as they currently are by NCCI) rather than eliminated through adjustments to the ELR's. Overall rates are not necessarily inadequate or excessive due to the existence of an experience rating plan off-balance.

5. Administration

Administration of the ERP is evaluated in Section VIII. There is evidence that the calculations resulting in ELR and D ratios are appropriately checked and documented in

EXPERIENCE RATING PLAN

NCCI files. Further, reasonable safeguards exist against manipulation of the data by the insured. Finally, the experience rating modification is calculated by computer, and a worksheet is produced showing the calculation and underlying data. This worksheet is sent to the carrier of record, and is made available to the insured and its agent or service provider.

B. Number of Years to be Used in Experience Rating

Objective (7b): To what extent would experience rating be more accurate if more than three years of data were used? Specifically consider the use of five years of data. Discuss the additional cost that might be applicable if five years of data were used.

Our evaluation of the number of years of experience to be included in the ERP is in Section VII. Our conclusions concerning the number of years to be used are as follows:

Our testing, using the Alternate formula and optimized RERP, suggest that the accuracy of the experience rating plan would be improved by expanding the experience period to five years from the current three years. Further testing based on data from additional states and, preferably, using fourth and fifth report data for the two additional years should be done before deciding to go ahead with this change.

Inclusion of the fourth and fifth years of experience would entail significant implementation costs as well as substantial ongoing costs.

In addition to the impacts on accuracy and cost, extension of the experience period to five years could affect the perception of the plan's reasonableness by policyholders. Some policyholders already consider it inappropriate to use data as old as the oldest year currently used in experience rating; the addition of two older years would exacerbate this perception.

C. Extension of the Plan to Small Risks

Objective (7c): What credits would be indicated for small loss free risks? To what extent would it be practicable to debit small risks for higher than expected losses?

EXPERIENCE RATING PLAN

The loss experience of small risks is described and evaluated briefly in Section III.D and in more detail in Section XI.

In Section XI, we describe a procedure for estimating the indicated credit for small loss free risks. In addition, we describe a Claim Free Credit Plan (CFCP).

Applying that procedure to the data for the states we have reviewed, the indicated credit for a small risk with three years of claim free experience is approximately 7%. In order to balance that credit, eligible small risks with at least one claim in three years should be debited approximately 13%. If the decision is made to implement a CFCP, we recommend that NCCI estimate the indicated credits and debits using the method we have described (including the noted refinements).

A CFCP is a compromise between the equity and loss control incentive of a full experience rating plan and the ease of operation of the current system of manual rates for small risks. If introduced, the CFCP would improve the equity of the premium charged to average sized unrated risks (i.e., those not eligible for experience rating). It is, however, likely to result in less equity than the current system for the largest and the smallest unrated risks. For large unrated risks (i.e., those close to, but below, the experience rating threshold) the CFCP may result in debits for risks whose experience is no worse than expected. For very small risks, the CFCP is likely to produce a larger swing in premium than is warranted by the credibility of actual experience. On average, the CFCP would cause unwarranted premium increases for large unrated risks and unwarranted decreases for the smallest risks.

We recommend against implementing a Claim Free Credit Plan of the type studied in this report, because of the inequities discussed above. Alternative approaches could reduce these inequities by varying the credits and surcharges according to the size of the risk and possibly according to the sizes of claims, but such a plan would be significantly more complicated and difficult to administer.

It should be noted that the credibility that would be assigned to the larger unrated risks, if they were eligible for experience rating, is high enough (see Exhibit 12) to suggest that experience rating would improve the accuracy of the rates for such risks. Our understanding is that NCCI has slowed the updating of eligibility requirements so that inflation will cause smaller risks to become eligible. We consider this appropriate.

EXPERIENCE RATING PLAN

D. Accuracy of Current Formulas Used to Calculate ELR's and D-Ratios

Objective (7d): Are the formulas used to calculate Expected Loss Rates (ELR's) and "D" ratios sound? Does the NCCI's method of introducing RERP tend to result in a revenue increase?

It is our conclusion that the methods used in calculating ELR's and D-Ratios could be improved in several ways in order to increase the accuracy of the experience rating plan. Both the ELR and D-ratio calculations are described and analyzed for accuracy in Section IV.

We believe that the calculation of ELR's can be significantly improved by:

1. Calculating loss development removal factors separately for serious, non-serious and medical categories, and utilizing each classification's distribution of serious, non-serious, and medical pure premiums as weights to calculate the average. As a temporary measure, NCCI may find it more practical to calculate loss development removal factors by hazard group until their ratemaking programs can be modified. This would result in more accurate expected losses to be compared against actual losses for each class.
2. Using a weighted rather than a straight average to combine loss development, trend, and benefit changes removal factors for the three policy years in the experience period. The weights for this average should be based on the actual distribution of ultimate expected losses by policy year, with adjustments to reflect any factors that have already been removed. We expect that this will result in more weight being given to the most recent policy period and a more correct overall effect of the plan.
3. Updating the tables of excess ratios to reflect more recent data. Test the impact of multiple claim occurrences and disease losses on the loss limitation factors. Modify these loss limitation factors if the additional limitations on these losses are significant.
4. Eliminating the 1.01 off-balance adjustment factor.
5. Changing the method used to calculate the trend removal factor to reflect the varying impact of medical trend recently included in the NCCI's industry group differentials.

EXPERIENCE RATING PLAN

We believe the D-ratio calculations can be improved as follows:

1. The total losses in the denominator of the D-Ratio should be adjusted to reflect the impact of the per claim and other loss limitations of the plan.
2. The data used to evaluate D-Ratios should include losses at first, second, and third reports. The current methodology includes losses only at first report.

E. Premium Impact of Implementing RERP

The premium impact of implementing the RERP is evaluated in Section IX. We conclude that the NCCI's method of introducing the RERP does not tend to result in a premium increase or decrease.

F. Experience Rating Plan Off-Balance Impact on Ratemaking Methodology

Objective (8c): Does the NCCI ratemaking formula accurately account for any off-balance due to the experience rating plan? Does the NCCI adequately adjust the expected loss rates (ELR's) and D-ratios to maintain off-balance at a reasonable level? What improvements could be made in the NCCI's procedures?

Standard NCCI methodology does not address changes in experience rating off-balance, although adjustments have been made by NCCI in some cases. The implicit expectation is that if rate revisions are made on a timely basis (regardless of whether the full amount of the requested rate revision is granted), then off-balance movements should be relatively small and have insignificant effects on overall rate levels. As Exhibit 5 demonstrates, however, a number of states have experienced significant off-balance movements.

We recommend that standard NCCI methodology identify off-balance levels and movements during the experience periods used for trending and rate level indications. An attempt should be made to determine the cause of significant off-balance swings whenever they are seen.

EXPERIENCE RATING PLAN

Proper action in response to significant off-balance swings would be a function of the cause identified. We would recommend that adjustments not be made when changes are attributed to a change in the mix of risks which are insured. The situations in which we would often expect that adjustments would be appropriate include:

1. a change in the experience rating plan itself (e.g., rules, such as eligibility requirements, or formulas such as those for calculating ELR's) or
2. delays in updating ELR's and D-ratios, due to prior delays in the approval of rate changes.

In these cases, some distortion could be expected to occur (if no adjustments are made) in the overall rate change indication, through misestimation of the trend factor and/or through an inconsistency between the average off-balance underlying the latest policy year and accident year loss ratios and that likely in the future period for which rates are being estimated.

One or both of the above situations have occurred in recent years in many states. The trends observed in Exhibit 16 suggest that such situations have in fact caused distortions in several states. However, the data underlying Exhibit 16 excludes interstate risks, because their effect on individual state off-balances has not been compiled by NCCI. Interstate risks account for over half of the total premium volume.

We have recommended certain adjustments (Section XII.A) in the ratemaking procedure to eliminate these distortions. However, to implement those adjustments, it is necessary to develop data on the average off-balances on an individual state basis, including interstate risks.

We recommend that NCCI develop data on average off-balances on an individual state basis, including interstate risks, for all policy years and calendar/accident years used in a rate filing (including those underlying the trend calculation). This data is essential both for monitoring average off-balances (to help detect distortions) and for adjustments to correct for the distortions.

NCCI has sometimes included appropriate adjustments in its rate analysis, but often has not. In some cases, the adjustments made by NCCI were designed to reduce or eliminate a change in average off-balance (by adjusting the ELR's), while it would have been more accurate to allow the off-balance to change and to make an offsetting adjustment to the

EXPERIENCE RATING PLAN

manual rates. If an adjustment is made to the ELR's in order to mitigate a change in average off-balance that would otherwise occur, this should be disclosed in the filing. It should be recognized that this type of adjustment represents a choice of stability in place of accuracy. Also, it is important to keep track of such adjustments and take them into account in subsequent rate analyses; if this is not done, they can result in a distorted view of trends or of experience loss ratios in subsequent filings.

G. Impact of Deductibles on Experience Rating

It is our understanding that data is currently reported to NCCI net of deductibles in eight states. Reporting data in this way significantly complicates and degrades the application of an experience rating plan. Theoretically, under such a reporting system, the ELR's and D ratios underlying expected losses for each risk should be adjusted to reflect the amount of that risk's deductible (if any). We understand that NCCI is currently developing an approximate adjustment procedure to apply in these states. We have not evaluated that procedure. Such an adjustment is needed in order to avoid inequity in the rating of risks.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

III. DETAILED DESCRIPTION OF THE PERP AND THE RERP

In this Section, we provide descriptions of the PERP and the RERP, with emphasis on the aspects of the plan that changed in the transition from the PERP to the RERP. We also discuss the concepts involved in the selection of the plan formulas and parameters, with some discussion of the advantages and disadvantages of alternate approaches.

A. Definition of Terms

In the equations that follow, the following definitions apply:

A = Actual Total Losses: the sum of actual case basis incurred losses, after reflecting certain limitations.

A_p = Actual Primary Losses: the primary portion (defined later) of actual total losses.

A_e = Actual Excess Losses: the excess portion of actual total losses ($A - A_p$).

E = Expected Losses: the expected loss rate (ELR) for each class times the payroll for each class divided by 100, summed over all classes and years.

E_p = Expected Primary Losses: the ELR for each class times the D-ratio for each class times the payroll for each class divided by 100, summed over all classes and years.

E_e = Expected Excess Losses: expected losses minus expected primary losses ($E - E_p$).

W = Weighting Value: number in the state's table of Weighting Values contained in the state pages of the Experience Rating Plan Manual. W is a number between 0 and 1, inclusive. W is based on the risk's volume of expected losses. W is multiplied by the primary credibility values to produce excess credibility values.

B = Ballast Value: number in the state's table of Ballast Values contained in state pages of the Experience Rating Plan Manual. B is also based on the risk's volume of expected losses. B is used directly in the calculation of primary credibility values, and indirectly in the calculation of excess credibility values.

EXPERIENCE RATING PLAN

B. Eligibility

Not every employer is eligible for experience rating. Although the minimum varies by state, a typical minimum annual premium of \$4,500 based on standard manual rates currently applies. Having satisfied this requirement, it is mandatory that the employer's manual premium be modified by the application of the state approved Experience Rating Plan. In contrast, the experience rating plans for most commercial casualty lines such as the plan promulgated by the Insurance Services Office (ISO) for general liability insurance are not mandatory in most states. In the remainder of this report, the term "rated risks" will mean risks eligible for experience rating.

C. Split of the Plans Between Primary and Excess Losses

In both the PERP and the RERP, losses are subdivided between primary and excess components. In both plans, less credibility is attributed to excess losses than to primary losses. Therefore, if two similar risks (A and B) each have the same dollar amount of loss experience, but A has a small number of large (i.e., including excess) losses, while B has a large number of small losses, B's experience results in a higher experience modification factor.

The RERP is a "single split" plan. The first \$5,000 of each claim is considered the primary loss portion and the portion, if any, of each claim above \$5,000 is considered the excess loss portion. For example, a \$12,000 loss would have a primary portion equal to \$5,000 and an excess portion equal to \$12,000 - \$5,000, or \$7,000.

The PERP is a "multi-split" plan in which a formula, rather than a fixed dollar value, determines the split between primary and excess losses. For claims less than \$2,000, the total loss is considered to be primary. Above \$2,000, the primary portion of a claim is given by the formula:

$A_p = 10,000 A / (A + 8,000)$, where A is the total loss amount.

For example, a \$10,000 loss would have a primary portion equal to \$5,556, and an excess portion equal to \$10,000 - \$5,556, or \$4,444. Given the nature of the above formula, the primary portion of a loss can never exceed \$10,000, regardless of the magnitude of the total loss on the claim.

EXPERIENCE RATING PLAN

The discount ratio (D-Ratio) represents the ratio of expected primary losses to expected total losses. These ratios vary by class and also differ between the PERP and the RERP, since the split points for these plans differ.

D. Credibility of the Plans

Credibilities under the RERP differ from credibilities under the PERP. For small risks, primary credibilities are larger and excess credibilities are somewhat larger under the RERP. For large risks, primary credibilities are smaller and excess credibilities are much smaller under the RERP. The effect of these credibility changes is to give a greater swing (range) to the experience modification factors for the smaller risks and a narrower swing to the modification factors for the larger risks.

For example, a small risk with better than average loss experience for its class, as measured by the class' expected loss, will receive a larger credit (i.e., a smaller experience modification factor) under the RERP than the PERP. Conversely, a small risk with worse than average experience will receive a larger debit (i.e., a larger experience modification factor) under the RERP than the PERP.

For larger risks, the credits and debits will have a narrower swing under the RERP than under the PERP and, therefore, the magnitudes of individual risk experience rating credits and debits will be reduced.

The credibilities for both primary and excess losses are defined by formulas under both the PERP and the RERP. For both plans, the credibilities are expressed as functions of total expected losses using the following formulas:

$$Z_p = E / (E + B), \text{ and } Z_e = W \times Z_p \text{ where}$$

Z_p = the credibility of primary losses,

Z_e = the credibility of excess losses,

E = the total expected losses for the risk during the experience period (normally 3 years), and

EXPERIENCE RATING PLAN

B and W are rating plan parameters which vary as functions of E and S (defined as the Self-Rating Point under the PERP and the State Reference Point under the RERP). Under the RERP, S is defined as 250 x the average cost per claim in each state. Under the PERP, S is 25 times the average serious cost per claim averaged with the prior year's value. B and W are determined by formulas which differ between the PERP and the RERP.

It is instructive to note the differences between the formulas for B and W in the PERP and the RERP, and the resulting effects on the plan credibilities and the experience modification factors. First, for the PERP:

B remains constant at \$20,000 for expected loss values ranging from \$0 to \$25,000. Above \$25,000, B decreases linearly as a function of expected losses to 0 at the self-rating point S. B remains equal to 0 at amounts exceeding S.

W equals 0 for expected loss values ranging from \$0 to \$25,000. Above \$25,000, W increases linearly as a function of expected losses from 0 to 1.0 at the self-rating point S. W remains equal to 1.0 at amounts exceeding S.

A consequence of B reaching zero at S under the PERP is that the primary credibility Z_p reaches 100% at S. In addition, because W reaches 1.00 at S, the excess credibility also reaches 100% at S. Thus, above S, the risk is deemed by the PERP to be fully credible and the prospective premium for the risk is based fully on the historical loss experience for that risk (with adjustments for trend, benefit changes and loss development) and not on the expected losses, as derived from NCCI manual rates.

Under the RERP, B and W are given by the following formulas:

$$B = E \times (.1E + .01S) / (E + .0028S), \text{ subject to a minimum of } \$7,500,$$

$$W = [(E + .0204S) \times (1.1E + .0128S)] / [(1.75E + .8204S) \times (E + .0028S)], \text{ subject to a minimum of } .07.$$

The nature of these RERP formulas determines that the credibility of neither primary or excess losses will ever equal 100%, even above the state reference point S. As E increases to S and beyond, B asymptotically approaches $.1 \times E$ and the primary credibility approaches $(1 / (1+.1)) = 91\%$. W asymptotically approaches $1.1/1.75 = .63$. The excess credibility therefore never exceeds $.91 \times .63 = 57\%$.

EXPERIENCE RATING PLAN

At low values of E, B equals \$7,500. This amount is much lower than \$20,000, which applies under the PERP for smaller values of E. Lower values of B translate to higher primary credibilities given the above formula for Z_p . Hence, for smaller risks, the RERP assigns higher credibility to primary losses than does the PERP.

At low values of E, W equals .07, compared to 0 under the PERP. Thus, excess losses always have credibility equal to at least 7% of the credibility of primary losses.

One aspect of the change in credibilities from the PERP to the RERP is that the loss experience for any risk, even one with expected losses exceeding the state reference point S, is not treated as being fully credible under the RERP. This is a logical change since full credibility implies that there is no predictive value associated with the manual rate when compared to the risk's historical losses. The PERP implicitly assumed full credibility of both primary and excess losses for risks with expected losses exceeding S.

The RERP always assigns less credibility to excess losses than to primary losses. This is also true for the PERP when expected losses are below S. This seems reasonable because of the more random nature of excess losses, and is consistent with the results of our study as described elsewhere in this report.

E. Formula for the Experience Modification Factor

The experience rating formula is the same under the RERP and the PERP. This formula, in its conceptual form is:

$$M = \frac{Z_p \times A_p + (1-Z_p) \times E_p + Z_e \times A_e + (1-Z_e) \times E_e}{E}$$

where M	= Experience Modification Factor
A_p	= Actual Primary Losses
A_e	= Actual Excess Losses
E_p	= Expected Primary Losses
E_e	= Expected Excess Losses
E	= Total Expected Losses = $E_p + E_e$
Z_p	= Primary Credibility
Z_e	= Excess Credibility

EXPERIENCE RATING PLAN

In the application of the plan, the above formula is not used directly. Since the credibilities are functions of expected losses E and parameters B and W, the formula for M is expressed directly as a function of these variables. The resulting formula becomes:

$$M = [A_p + B + W \times A_e + (1-W) \times E_e] / [E + B]$$

A maximum of three years of loss experience is normally used in this formula. Generally, the three years are consecutive policy periods ending 12, 24 and 36 months prior to the effective date of the experience modification factor.

Actual losses are case basis incurred losses as reported to NCCI through the Workers Compensation Statistical Plan as of the loss evaluation date. They are not adjusted by NCCI in the rating calculation, except that very large losses are truncated at certain loss limitations. Expected losses are computed by multiplying the exposure units (i.e., number of hundreds of dollars of unlimited payroll) by the "expected loss rate" (ELR) for each risk class. The ELR is calculated by NCCI from the existing manual rates for each class and state by adjusting for the impacts of:

- expenses and profit trend
- subsequent law changes
- loss development
- an "off-balance" adjustment
- large loss limitations.

With these adjustments, the ELR's x exposures should be comparable to the reported losses and, if the risk is average within the NCCI classification structure, the resulting experience modification factor should ideally equal 1.00.

Expected losses must also be divided between primary and excess components. This is done using discount ratios, or D-ratios, which vary by class. The D-ratio is the expected ratio of primary losses to total losses.

If an insured operates in more than one of the states where interstate rating applies, special procedures must be applied in the application of the ERP since different state reference points (S) apply and hence different B and W values apply. To compute the B and W values for the interstate insured, those values are computed for each state separately, given the total expected losses for the insured in all states combined, and the results are averaged

EXPERIENCE RATING PLAN

together for the states using the expected losses for each state as weights. After B and W values are computed in this manner, the experience modification factor is computed as it would be for an intrastate insured.

F. Other Experience Rating Plan Rules

1. Definition of Risk - Combination of Entities

The experience of several entities and policies must sometimes be combined for purposes of experience rating. The rules for the combination are based on common majority interest. Broadly speaking, all entities which have common ownership (50% or more) are combined into a single unit for purposes of experience rating. In practice, the rules for the combination of entities are quite complex. A complete discussion of these rules is contained in the NCCI Experience Rating Manual. A single entity or a group of entities which are combined to form the basis for an experience modification factor is called a "risk."

2. Experience Period

The experience period is the historical time frame which defines the experience to include in the experience rating calculation. It generally consists of the three most recently completed policy years that expired at least one year before the effective date of the experience modification factor. Rules exist which provide longer or shorter experience periods in certain circumstances.

3. Plan is Mandatory

The Experience Rating Plan is mandatory for all eligible risks. Two tests are used to determine experience rating eligibility. If a risk satisfies either test, it is eligible. The first test compares the premium at manual rates for the latest two years combined to a threshold. This first threshold is currently \$9,000 to \$10,000 in most states, but some states have thresholds as low as \$3,500. The second test compares the premium averaged over more than two years to an amount which is half of the first threshold.

EXPERIENCE RATING PLAN

4. Payrolls and Losses

The actual audited payroll and loss experience of the risk is collected for the policies in the experience period. It is based on the data submitted through the Workers Compensation Statistical Plan. The losses are defined in the Statistical Plan. Generally, losses are valued as of 18 months after policy inception for the most recent of the three policy years, 30 months after inception for the middle policy year, and 42 months after inception for the earliest policy year.

5. Loss Limitations

The losses that are used in the experience rating plan are limited to certain amounts. Losses are divided into categories for this purpose. The categories are: state workers compensation act losses; United States Longshore and Harbor Workers (USL&HW) compensation act losses; employers liability claims; and disease losses.

State act claims and USL&HW act claims have both per claim (i.e., per injured worker) limits and per occurrence limits. The Prior Experience Rating Plan calculated the per claim limitation as 10% of the Self Rating Point. As mentioned earlier, the Self Rating Point is approximately equal to 25 times the average serious cost per claim. The Revised Experience Rating Plan calculates the per claim limitation as 10% of the State Reference Point. The State Reference Point is approximately equal to 250 times the average cost of all claims (serious and non-serious). In general, the Revised Experience Rating Plan results in much lower per claim loss limits.

The per occurrence limit is twice the per claim limit. The maximum primary loss amount per claim is \$5,000 for RERP and \$10,000 for PERP. Per occurrence primary losses are limited to twice the maximum primary amount per claim.

Employers liability losses have only a single per claim limit.

For each year in the experience period, the total of disease losses is limited to three times the state act per claim limitation plus 120% of the risk's expected losses for that year. Primary disease losses are limited to three times the maximum primary amount plus 40% of the risk's expected losses for that year.

In most cases, these loss limitations have been substantially lowered in the transition from the PERP to the RERP.

EXPERIENCE RATING PLAN

6. Intrastate and Interstate Operation of the Plan

The experience rating plan contains special rules for risks with operations in more than one state of the group of states where interstate rating applies. If a risk is eligible for experience rating in at least one such state, but has experience in more than one such state, the interstate rating rules apply in those states. In general, interstate rules provide for the calculation of credibilities based on the volume of expected losses in all those states combined. Intrastate rating is used in the states where interstate rating has not been approved by the regulatory authorities. Interstate rating has been adopted as a rating plan by 39 states and the District of Columbia. Of the remaining 11 states, 5 states have intrastate rating plans only and 6 states have exclusive state funds. Intrastate credibilities are based only on the volume of expected losses within the state being rated.

G. Comparison of NCCI, ISO and Alternate Formulas

The formula described above has been used by NCCI for many years. However, alternative formulas present some advantages and disadvantages relative to the one used.

Although the formula described above is used for workers compensation, a different formula is used by Insurance Services Office (ISO) for commercial automobile and general liability lines of insurance. For these lines, only basic limits (i.e., primary) losses enter into the rating calculation and an experience modification factor is computed based upon a comparison of basic limits losses against expected basic limits losses.

Under the ISO approach, the experience modification factor, which is computed from the basic limits loss data, is applied not only to the basic limits manual premium, but also to the excess limits manual premium. The assumption is made that the ratio of excess limits premium to basic limits premium equals the excess limits factor, which should remain constant for all risks within a class. Therefore, the excess premiums charged to cover excess losses vary, depending on the experience modification factor determined from the basic limits, or primary, loss data.

The NCCI approach is significantly different from the ISO approach with respect to the calculation of premium to cover excess losses. Under the NCCI approach, the estimated excess losses are not affected by the actual primary losses. This difference can be illustrated with a hypothetical example:

EXPERIENCE RATING PLAN

Suppose a risk has:

Expected primary losses	= \$30,000
Actual primary losses	= \$15,000
Primary credibility	= 50%
Expected excess losses	= \$60,000
Actual excess losses	= \$25,000
Excess credibility	= 5%

Using the NCCI formula, the modification for the risk would equal $(.50 \times 15 + .50 \times 30 + .05 \times 25 + .95 \times 60)/90 = .90$

For this example, the risk's premium is decreased by 10%, although primary and excess losses are only half as high as the expected losses and the credibility of the primary losses is 50%. The credit is only 10% because the credibility of the excess losses is only 5% and a large portion of the total expected losses are excess, i.e., the D-ratio equals 1/3, or .33.

In our example, the expected excess losses = \$60,000, while the expected primary losses = \$30,000, a multiple of 2:1. Yet, when we compute credibility weighted excess losses equal to $.05 \times 25,000 + .95 \times 60,000 = 58,250$ and credibility weighted primary losses equal to $.50 \times 15,000 + .50 \times 30,000 = 22,500$, the ratio $58,250/22,500 = 2.59$ exceeds 2:1. It therefore seems likely that, for this risk, the NCCI formula over estimates the expected value of excess losses. This would be true if (as our tests indicate) a lower than expected amount of primary losses indicated proportionately lower excess losses, in the absence of credible excess loss data.

Under the ISO approach, the modification based on primary losses is, in effect, applied to the expected excess losses. Continuing our example, the experience modification factor would then be defined as:

$$\begin{aligned} M &= M_p = [Z_p \times A_p + (1-Z_p) \times E_p] / E_p \\ &= (.50 \times 15 + .50 \times 30)/30 = .75 \end{aligned}$$

The alternate approach recommended in this report is a hybrid of NCCI and ISO approaches, in which the expected excess losses are adjusted by an experience

EXPERIENCE RATING PLAN

modification factor based on primary losses. The formula for the overall modification then becomes:

$$M = [Z_p \times A_p + (1-Z_p) \times E_p + Z_e \times A_e + (1-Z_e) \times E_e \times M_p] / E$$

In our example, M equals $(.50 \times 15 + .50 \times 30 + .05 \times 25 + .95 \times 60 \times .75)/90 = .74$

The alternative formula can be expected to be more accurate if it can be shown that primary and excess losses for individual risks are significantly correlated (i.e., risks whose primary losses tend on average to be higher than the expected primary losses - based on ELR's - have proportionately higher excess losses on average). In our study, described in Section V.D of this report, we find that such a correlation exists.

In the preceding example, we have used the same credibilities for all three experience rating formulas (i.e., the RERP, ISO and Alternate formulas) for illustration purposes. However, the optimal credibilities actually are substantially higher for the RERP formula than for the Alternate formula, as shown in Exhibit 12. (We have not studied the optimal credibilities for the ISO formula, but would expect them to be closer to those for the Alternate formula than the RERP formula).

The reason the RERP primary credibilities are higher is to compensate for the fact that the excess loss estimate in that formula does not take into account the informational value of past primary losses in estimating whether the risk's future excess losses (on average) will be higher or lower than expected. The reason the RERP excess credibilities are also higher than the Alternate excess credibilities is that the unadjusted expected excess losses (used in the RERP formula) are not as accurate as estimators of future excess losses as are the adjusted expected excess losses (used in the Alternate formula). That is, the estimate against which the actual excess losses are credibility weighted is a poorer estimate in the case of the RERP and, as a result, the RERP gives greater weight to the actual excess losses.

The difference in credibilities results in experience modification factors that are generally much closer to one another than indicated by the preceding example. In effect, the RERP provides a closer approximation to the appropriate experience modifications by using higher credibility factors.

In the above example, if the Alternate formula credibilities (.50 for primary losses and .05 for excess losses) are left unchanged but the corresponding, higher RERP credibilities (approximately .95 for primary losses and .10 for excess losses) are used in the RERP

████████████████████

EXPERIENCE RATING PLAN

formula, the modification produced by the RERP formula becomes: $(.95 \times 15,000 + .05 \times 30,000 + .10 \times 25,000 + .90 \times 60,000)/90,000 = .80$.

This is closer to the Alternate formula estimate of .74 than was the RERP estimate calculated previously (.90).

EXPERIENCE RATING PLAN

IV. ANALYSIS OF OPERATION AND OFF-BALANCE OF PERP AND RERP

This Section is divided into several sub-sections, each containing a description and evaluation of technical aspects of the plan. We describe and evaluate the calculation of Expected Loss Rates (ELR's), D-ratios, and the plan off-balance.

A. Description of Expected Loss Rate (ELR) Calculation

The expected losses used in both the PERP and the RERP are based on the manual rates and the risk's payrolls by class. However, because the actual losses used in the plan are undeveloped and untrended, and include no provision for expense, several adjustments are made to the manual rates to put them on the same basis. These adjustments are made through the use of Expected Loss Rate Factors (ELRF's) which are multiplied by the manual rate to produce the ELR for each class. ELRF's are calculated separately for each of the four hazard groups. (NCCI groups classes into four "hazard groups" on the basis of the expected average claim size within each class.) These four ELRF's are then multiplied by the manual rates by class to produce Expected Loss Rates (ELR's). The expected losses used in the experience rating plan are the products of the ELR's and the risk's payroll by class.

A sample calculation of ELRF's is shown on Exhibits 1 and 2. The sample calculation is not an NCCI form, but is our consolidation of several of their forms. This is done for ease of exposition and, except for potential rounding differences, will produce the same results.

The ELRF's can be thought of as including the following six factors:

- Expense and profit removal factor
- Trend removal factor
- Benefit change or law amendment removal factor
- Loss development removal factor
- Off-balance adjustment factor
- Loss limitation factor

The following is a detailed description of each of these factors. Row numbers refer to the rows on Exhibit 1.

EXPERIENCE RATING PLAN

1. Expense and profit removal factor - The rates (in administered pricing states) include allowances for insurance company expenses and underwriting profit (positive or negative). Row 1 shows the Target Cost Ratio, usually shown in Exhibit II of the rate filing. This ratio represents the portion of the proposed manual rate which is expected to be used to pay losses and loss adjustment expenses. In Row 3 the Target Cost Ratio is divided by the loss adjustment expense factor (Row 2) to obtain the expense and profit removal factor. In the sample calculation shown in Exhibit 1, this factor implies that (1-.646) or 35.4% of the manual rate represents allowance for profit and expenses. In loss cost states, the expense and profit removal factor generally removes only loss-based assessments and loss adjustment expenses (if applicable).
2. Trend removal factor - The average accident date underlying a set of manual rates is usually about three years more recent than the average accident date of claims entering the experience rating formula. Thus, in order to be comparable to the actual losses in the experience period, the manual rates need to have three years of loss ratio trend removed. This "de-trending" is accomplished in two steps. The Financial Data Loss Ratio shown in Row 4 is the loss ratio used to calculate the overall change in manual rates. It reflects adjustments to current rate level, ultimate loss level, current benefit level, and trend to the midpoint of the period in which the rates will be used. Row 7 shows the Statistical Plan Loss Ratio trended to the average date of loss of the experience period. The Statistical Plan Loss Ratio is generally one to two years earlier than the experience rating period. Since the Statistical Plan Loss Ratio is also adjusted to current manual rate level, ultimate loss level, and current benefit level, the ratio of Rows 7 and 4 represents the trend from the experience period to the period in which the rates will be used. In the example shown in Exhibit I for instance, the losses implicit in manual rates need to be reduced by (1-.841) or 15.9% to bring them back to the cost levels existing when the actual losses in the experience period occurred.
3. Law amendment removal factor - The latest rates include the impact of law amendments subsequent to the experience period. Law amendment factors are calculated to reflect the average impact of law changes between the experience period and the period in which the rates will be used. Separate law amendment factors are calculated by type of injury, and a weighted average law amendment factor is calculated for each of the three years of the experience period (Row 9). Statistical plan total losses for each policy year for all classes combined are used as weights. The law amendment removal factors are the inverses of the law amendment factors.

EXPERIENCE RATING PLAN

4. Loss development removal factors - The losses implicit in the manual rates are projected to an ultimate level. The losses entering the experience rating period, however, are valued as of 18 months after the policy effective date for the most recent year, 30 months for the middle year, and 42 months for the earliest year. These are the statistical plan first, second, and third reports, respectively. Therefore in order to be made comparable, the losses included in the manual rates need to be adjusted to remove projected development of case incurred losses subsequent to these evaluations. For each year in the experience period, Row 10 shows the expected ratio of reported case incurred losses to ultimate losses. For example, for the 1986-87 period (the earliest year in Exhibit 1), third report losses represent approximately 90.7% of ultimate losses. Thus the ultimate losses included in the manual rates would have to be reduced by $(1-.907)$ or 9.3% to be comparable to 1986-87 actual losses.

Law amendment removal factors and loss development removal factors are calculated separately for each of the three policy periods included in the experience period. These two sets of factors are combined in Row 11. A simple unweighted average is then taken of the resulting three factors to produce a single law amendment and development removal factor.

5. Off-balance adjustment factor - The factor shown in Row 12 is a one percent adjustment factor which Gillam¹ explains is designed to reflect the fact that, on average, insureds large enough to be eligible for experience rating have loss ratios (at manual rates) approximately one percent lower than average.

6. Loss limitation factor - A final adjustment is made to exclude the impact of large losses that exceed the per claim and other loss limitations (described in Section III.F.5) applied to data that enters the experience rating modification formula. The method used is an adaptation of the method described by Harwayne² and used for many years in retrospective rating. An example of the application of this method is presented in Exhibit 2.

¹ William R. Gillam, "Calculation of Experience Rating Values and Plan Parameters," *Casualty Actuarial Society Forum*, Spring 1990, p48.

EXPERIENCE RATING PLAN

Line 1 of Exhibit 2 shows a \$49,000 amount, labelled as 10% of the State Reference Point. This is the loss limitation amount in this example.

Lines 2, 5 and 8 are the average reported claim costs (before any limitations) for fatal, permanent total, and major permanent partial claims, respectively, during the three year Worker's Compensation Statistical Plan period in the rate filing.

Lines 3, 6 and 9 are ratios of the \$49,000 loss limitation amount to the average claim cost for each type of loss.

The ratios from lines 3, 6 and 9 are then entered into an excess loss distribution table to obtain ratios of excess losses (above the \$49,000 amount) to total losses for each type of loss. These ratios are shown on lines 4, 7 and 10.

The excess to total ratios on lines 4, 7 and 10 are then averaged together to produce an overall average excess ratio on line 12. The proportions of losses by injury type are used as weights. Note that it is assumed, as an approximation, that minor permanent partial, temporary total and medical only injury types do not generate losses above the limitations. These calculations are done separately for each of the four hazard groups.

The loss limitation factors in line 13 are the complements of the weighted average excess ratios in line 12. They are used as factors to adjust the unlimited rates to the level anticipated for losses with the per claim and other limitations used in experience rating. Since the level of excess losses varies considerably among hazard groups, a separate factor is used for each hazard group.

The ELRF's are calculated as the products of the factors described above. There is a separate factor for each hazard group. The product of the ELRF and the manual rate equals the ELR used for experience rating.

B. Evaluation of the ELR Calculation

We have evaluated a sample of the calculations by NCCI of the expected loss rates for four states. We found that the worksheets were correctly filled out and calculated with the appropriate data. In addition, there is evidence in the files of who was responsible for completing the forms, as well as checksheets that identify unusual results to be brought to

EXPERIENCE RATING PLAN

the attention of the supervisor. However, we believe that the calculations could be improved in several important respects.

1. Trend removal factor - In calculating manual rates, NCCI has implemented a procedure that adjusts the industry group differentials for relative differences in wage growth by industry group. The purpose for this adjustment is to correct the medical trend factor to properly reflect varying wage growth by industry group. The net effect of this ratemaking procedure is to apply slightly different trend factors to each of the manufacturing, contracting, and all other industry groups. The impact of these differential trend factors should be, but are not currently, reflected in the removal of trend for the calculation of ELR's.

We recommend that NCCI reflect the varying impact of trend on each of the three industry groups in the calculation of ELR factors. This will require the calculation and application of separate ELR factors by industry group. We understand that the current NCCI ratemaking computer programs are equipped to accommodate different ELR factors by industry group.

2. Loss development removal factors - The most important changes we recommend in the calculation of ELR's involve the loss development removal factors discussed in Section IV.A.4 above. We believe that the accuracy of these factors can be substantially improved in two ways. The first is to better reflect the distribution of serious and non-serious losses by class. The second is to reflect the actual distribution of expected losses among the three policy periods that make up the experience period. The following Sections discuss each of these changes in more detail.

2a. Loss development reflecting the class distribution of serious, non-serious and medical losses.

During the rate review process, NCCI divides losses into four categories: serious indemnity, serious medical, non-serious indemnity, and non-serious medical. When calculating manual rates by class, loss development is applied separately for each of these categories. In general, the serious loss development factors are far larger than the non-serious loss development factors. In the experience rating calculation, however, the amount removed through the application of the ELR factor is based on the average amount of loss development, using the statewide average distribution of losses by category. Thus, while on average the correct amount is removed, the amount removed for any particular class is likely to be inaccurate.

EXPERIENCE RATING PLAN

If a class has predominantly serious losses, the manual rate will include a greater than average provision for loss development. Since only the average loss development is removed through the ELR factor, the expected losses will be too high when compared to the undeveloped actual losses for that class. Thus, NCCI ELR's used in the experience rating plan are overstated for the more hazardous classes (those with greater proportions of serious losses) and are understated for the less hazardous classes. The effect of this is to understate the indicated experience modification factor for hazardous classes and overstate the factor for less hazardous classes.

The results of our tests support this conclusion. The table below shows normalized ratios of actual to expected losses, averaged over all six years of data examined in this study. Expected losses were uniformly adjusted so that the aggregate actual-to-expected loss ratio equaled 1.0 in each of the years (normalized). The averages use the amounts of expected losses in each cell as weights. The downward trend across hazard groups is consistent with our prediction that expected losses are, in general, underestimated for the less hazardous classes and overestimated for the more hazardous classes. We were not able to ascertain the reason for the high ratio for Florida in hazard group IV other than the comparatively smaller volume of data and the higher volatility of the losses for this hazard group. Nevertheless, the pattern is in general consistent and illustrates the need for some modification to NCCI's current procedure for calculating ELR's.

Table I - Normalized Ratios of Actual to Expected Losses by Hazard Group

HAZARD GROUPS	STATE			
	Florida	Maine	Nebraska	Utah
I	1.111	1.366	1.346	1.592
II	1.029	1.219	1.104	1.051
III	.969	.858	.925	.976
IV	1.304	.890	.715	.877
ALL	1.000	1.000	1.000	1.000

There are two changes that should be reasonably practical to implement that will help to correct for this problem. The first change is to calculate loss development removal factors separately by hazard group. These factors would then reflect the different distribution of

EXPERIENCE RATING PLAN

serious and non-serious losses in each hazard group. It should be possible to implement this change immediately without substantial procedural or programming changes. Distributions of serious and non-serious losses by hazard group are already used in the calculation of the loss limitation factor (discussed in Section IV.A.6 above). These distributions could also be used to calculate average loss development factors that vary by hazard group. Since the final ELR factors already vary by hazard group, no additional modifications need to be made.

The second change would be more exact but would also be more difficult to implement. It would consist of calculating loss development removal factors separately by class, directly using the mix of serious, non-serious, and medical losses within the class. We recommend that NCCI use the pure premiums underlying the proposed rates (see part IIA - NCCI Ratemaking Procedures, page 71) as weights to apply to serious, non-serious and medical development factors. NCCI currently uses these pure premiums underlying proposed rates to calculate the classification's D-ratio. We are suggesting they employ a similar method to calculate ELR's. This would reduce random fluctuations in proportions of losses by type of injury for small volume classes.

We recommend that the first change (by hazard group) be adopted immediately and replaced by the second change (by serious, non-serious, medical) when this more complicated method can be implemented.

2b. Loss development by policy period reflecting the actual distribution of ultimate losses

The second problem with the current procedure involves the use of an unweighted average to combine the loss development removal factors for the three policy years included in the experience period. This method assumes that all three of the policy years have equal volumes of expected ultimate losses. This is unlikely to be true in practice. Because of trend and upward adjustments in benefit levels, we would expect the more recent policy years to have higher volumes. In addition, experience rated risks are more likely to have exposure in the more recent periods. New businesses are constantly starting; thus, not all experience rated risks have been in business long enough to have exposures in each of the experience rating policy periods. Thus, the distribution of exposures will be skewed toward the more recent periods.

The chart below shows the comparative level of ultimate expected losses and number of risks for all experience rating risks developing rated-size exposures in 1988 based on the

EXPERIENCE RATING PLAN

sum of the data in the four states sampled. As expected, this distribution is skewed toward the more recent policy periods.

Chart 1 - Number of Risks and Expected Losses as a percent of the Latest Year

The skewed exposure distribution of rated risks indicates that there is comparatively more first report than third report data used in experience rating. The current calculation of ELR factors assumes an equal distribution of exposures. Thus, the actual data used in experience ratings is more recent (i.e., less mature) than contemplated by the current calculation of ELR's. The fact that actual losses are less mature than expected losses has two offsetting effects. The impact of trend and benefit level changes causes the average level of actual losses to be higher than contemplated by the current ELR's. The impact of loss development causes the average level of actual losses to be lower than contemplated by the current ELR's.

The impact of loss development is likely to be greater than the impact of benefit level changes and trend, in most states. This results in ELR's that are too high in these states. This implies a tendency to underestimate experience modification factors (absent other distortions).

EXPERIENCE RATING PLAN

This could be corrected in several ways. The first is to calculate separate ELR's for each year of the experience period. While this would be the most accurate approach, it would also be the most difficult. Substantial changes would need to be made to the experience modification programs and the ratemaking programs. In addition, ELR factors, which already vary by hazard group, will need to vary by experience period as well. This would substantially add to the complexity of an already complex rating program.

We recommend a less accurate, but more practical method. This method would be to calculate approximate policy period weights based on data similar to that in the table discussed above. As in the current methodology, average development, trend, and amendment factors would be calculated. However, these averages would be weighted rather than unweighted. The weights would be based on the ultimate expected losses, by policy period, with adjustments to reflect any factors that have already been removed. For example, if trend is viewed as being removed first, and then loss development, then the ultimate expected losses would be reduced to remove trend (by policy period) to calculate the weights to be applied to loss development removal factors. Note that this method would correct the overall bias but might still leave significant inaccuracies for individual risks.

3. Off-balance adjustment factor - We believe that the expected losses used in experience rating should be based on the average loss level underlying manual rates. If the actual level of an individual risk's losses was equal to this average, its experience modification factor would be 1.0 and it would be properly charged the manual rate. If the actual level of an individual risk's losses was higher, then to the extent its actual losses were credible, it would receive a debit to the manual rate. Likewise if the actual level of an individual risk's losses was lower, then to the extent credible, a credit would be applied to the manual rate.

The 1.01 off-balance adjustment factor applied by NCCI in the calculation of ELR's reduces the expected losses from the level implicit in the manual rates and, thereby, increases the modification factor slightly. Depending on the actual cost differential between experience and non-experience rated risks, this has the potential to create a slight subsidy of non-experience rated risks by experience rated risks. We believe that the 1.01 adjustment factor should be eliminated from the ELR calculations.

An example may help to clarify this:

Assume (temporarily) that both experience rated risks and non-experience rated risks have the same loss ratio at manual rates. Then, if the 1.01 factor were not incorporated in the

EXPERIENCE RATING PLAN

ELR's, the ELR's would also reflect the average experience of all risks. The resulting experience modifications would average 1.0 and the manual rate would properly be the average rate charged.

Alternately, suppose that experience rated risks always had loss ratios (at manual rates) that averaged one percent lower than those of non-experience rated risks. An average experience modification credit of one percent would properly reflect the cost differential. However, if an individual risk's actual losses averaged one percent lower than expected losses, the experience modification factor would be a credit of less than one percent. This is because the credibility dilutes the true cost differential. We have generally found that a one percent change in expected losses produces roughly a one-third percent change in experience modification factor. Thus, a true cost differential of one percent would result in an average experience modification factor of about .997.

If, under this circumstance, the NCCI's 1.01 correction for off-balance factor is applied, the average experience modification factor of .997 will move to 1.000. Thus, if experience rated risks have one percent better loss ratios than non-rated risks, the 1.01 factor eliminates the credit that otherwise would result from the partial consideration of this difference by the credibility factors.

If the 1.01 factor is maintained even if there is no true cost differential, ELR's will be one percent too low, manual rates will be too low, and experience modifications will be too high.

If it can be reasonably demonstrated that there is a true underlying cost differential between experience rated risks and non-experience rated risks, then it would be appropriate to reflect this difference in the manual rating system instead of the experience rating plan. Attempts to build such an offset into the experience rating plan, will create inequities due to the partial credibility ascribed to individual risk experience.

We believe that the ELR's should reflect the loss costs underlying manual rates. In this manner, the experience modification factors of experience rated risks will reflect differences, to the extent they are credible, between a risk's actual losses and those reflected in the manual rates. We therefore recommend that NCCI eliminate the use of the 1.01 correction for off-balance factor.

4. Loss limitation factor - The Harwayne normalized loss distribution tables used to calculate excess ratios are based on data that is now approximately twenty years old. The

EXPERIENCE RATING PLAN

lower per claim loss limitations effective with the Revised Experience Rating Plan place more importance on accurately calculating these values. Table II below shows the decreases in loss limitations that would occur in the change from PERP to RERP, for the four main sample states used in this study.

Table II - Loss Limitations Under PERP and RERP

State	State Act Loss Limitations (per claim)	
	Prior Experience Rating Plan	Revised Experience Rating Plan
Florida	165,500	70,500
Maine	187,000	111,000
Nebraska	143,500	49,000
Utah	109,000	38,500

While the Harwayne tables reflect changes in the scale of the claim size distribution through the use of ratios to the average, the shape of the claim size distribution has probably changed in the last twenty years. We recommend that NCCI update the study used to develop these tables. Studies of this nature should be performed regularly by NCCI (e.g., every 3 years) since it is quite possible that the shapes of the workers compensation claim size distributions are changing, and the limited expected losses should reflect these changes.

Exhibit 3 shows the results of our comparison, based on data provided to us by NCCI, of the predicted against the actual loss limitation factors for Florida, Maine, Nebraska, and Utah. The predicted loss limitation factors are calculated in the manner shown in Exhibit 2. The results appear reasonably consistent with the indications, given the randomness inherent in excess losses. However, because of the age of the study used to construct the Harwayne tables, and the increased importance of the loss limitation factors under the Revised Experience Rating Plan, we believe NCCI should review and potentially revise the loss distribution tables used to calculate the loss limitation factors. NCCI programs used to extract the data we requested for this study could be easily adapted to extract the size of

EXPERIENCE RATING PLAN

loss distributions needed to create revised excess loss tables. We recommend that NCCI undertake such a study.

The NCCI method for calculating loss limitation factors does not reflect the additional limitations that are applied per-occurrence or the special limitation of disease losses. Given the latency associated with disease losses, it is possible that they emerge beyond the first, second, and third report used in the experience period. If so, the loss development that is removed will appropriately account for this limitation. However, we believe that NCCI should evaluate the impact of both multiple claim occurrences and disease losses. NCCI should modify their calculation of loss limitation factors if the additional limitations on these losses are significant.

C. Description of D-Ratio Calculation

The D-ratios are the ratios of expected primary to total expected losses (after capping by the per claim limit) for a risk. Partial D-ratios are calculated separately for serious, non-serious, and medical losses. The overall D-ratio for a class is the weighted average of the partial D-ratios using serious, non-serious and medical pure premiums as weights. A sample calculation of partial D-ratios is included in Exhibit 4. The following is a description of that calculation.

Rows 1 and 2 show the latest available total indemnity and medical losses from the statistical plan as of first report, before the impact of loss limitations. Columns A, B, and C divide these losses into three categories based on whether the loss is serious, non-serious, or medical only.

Row 4 shows the corresponding primary losses again subdivided by category.

Rows 5 and 6 show a subdivision of the primary losses in Row 4 between medical and indemnity based on the corresponding breakdown for all losses (Rows 1 and 2).

The partial D-ratios for serious and non-serious losses reflect only indemnity while the ratio for medical includes all medical payments. An adjustment is made to account for this in Rows 7 and 8. The first report D-ratios are then calculated in Row 9 as the ratio of Rows 7 and 8.

EXPERIENCE RATING PLAN

The primary losses in Row 7 are based on the loss distribution among serious, non-serious, and medical losses that exists at first report. However, because development beyond first report is significantly different for each loss category, that distribution will change at second and third reports. In order to adjust for this, Row 11 shows the distribution by loss category of the sum of the latest three years of losses adjusted to current benefit levels, ultimate loss levels, etc. The final partial D-ratio factors are then the products of the first report partial D-ratio factors in Row 9 and the ratios of the three year loss category distribution in Row 11 and the first report loss category distribution in Row 10.

D. Evaluation of D-Ratio Calculation

We believe that there are two improvements that should be made in the current method of calculating D-ratios. D-ratios are currently based on first report statistical plan data. However, they are applied to expected losses that are combinations of first, second, and third report data. It is likely that loss development affects total losses more than primary losses. As a result (before considering the other distortion discussed below), the average D-ratios tend to be overstated and the experience modification factors tend to be understated.

Another distortion works in the opposite direction. The losses used in the denominator of the D-ratio calculation are losses unlimited by the loss limitations. However, D-ratios are applied to expected losses that have been reduced to reflect loss limitations. The use of unlimited losses in this manner tends (before considering the other distortion mentioned above) to understate the D-ratios and overstate the experience modification factors.

The net effect of these two distortions depends upon the relative level of loss development and the amount of excess losses. The Revised Experience Rating Plan lowers the loss limitations substantially. Therefore, the impact of the losses in excess of loss limitations assumes greater importance than under the Prior Experience Rating Plan.

We recommend basing D-ratios on three years of data (first, second, and third report), and reflecting the impact of the loss limitations in the denominator used to calculate these ratios. If this is not possible, tests should be performed to ascertain the relative impact of the primary and total losses, and adjustments should be made accordingly. The proportion of losses in excess of the loss limitation is directly estimated in the calculation of ELR's and should be removed from the denominator of the D-ratios.

EXPERIENCE RATING PLAN

E. Description of Plan Off-Balance

The off-balance of the Experience Rating Plan refers to the difference between manual and standard premium, and reflects the average experience modification factor. The average experience modification factor can differ from 1.0 for a variety of reasons. First, there is randomness in any collection of actual risk experience, and this randomness will affect the average experience modification factors. Second, risks that are eligible for experience rating can be better or worse, as a group, than average. Third, among the group of rated risks, the loss ratios may vary by size of the insured. Since the larger risks also receive larger credibility, this will affect the plan off-balance. Finally, an off-balance may result if the ELR's or D-ratios are overestimated or underestimated. The accuracy of ELR's and D-ratios is evaluated in sections IV.B and IV.D of this report.

We would expect that the average level of ELR's could be estimated fairly well for the experience periods to which they are applied. For example, unanticipated trends should not be a problem as comparable overall statistical plan data is available for 1-2 years prior to the experience rating experience period and financial loss data is available for one or more years after the experience period used for experience rating. A similar situation exists regarding loss development and law amendment adjustment. Thus, development, trend and law amendment adjustments are essentially an interpolation problem, rather than an extrapolation problem.

Significant off-balances can develop if ELR's are allowed to become out of date. NCCI generally revises ELR's at the same time that it revises rates. If rates are not filed or approved regularly, then the ELR's will not be updated through the normal rate review cycle. During a period of positive trends, if ELR's are not updated, the expected losses used in experience rating will be too low by the amount of trend between the current experience rating period and the experience period originally targeted by the ELR's. This will cause experience modification factors to rise, on average.

However, because credibility only gives partial weight to actual experience, the increase in experience modification factors will be less than the increase in costs due to the trend factor. With significant positive trends, outdated rates will result in premium inadequacies. These inadequacies will be lower for the larger risks with significant credibilities, and higher for the non-rated and smaller rated risks with lower credibilities.

If rates are regularly updated, however, average experience modification factors should normally remain relatively close to 1.0. This may be true even if rates are actually

EXPERIENCE RATING PLAN

inadequate or excessive. Rates may, for example, be inadequate if the actual loss development applicable to the latest financial data is higher than predicted by the selected factors, if the trend factor is too low to compensate for the actual level of cost increases, or if the expense and profit provisions are less than the actual needs. Since all the expense, profit, development, trend, and other projections built into the manual rate are removed to calculate ELR's, inaccuracies in these values will not have a material effect on the resulting experience modification factors. However, if rates are inadequate or excessive to a large degree, the average experience modification factor may differ from 1.00.

Thus, experience modification factors will not generally correct for inadequate or excessive rates.

F. Evaluation of Plan Off-Balance

Adjusting expected losses and expected primary losses to equal the corresponding actual losses in total for all experience rated risks in a state, should result in an average experience modification factor of about 1.0 if risks have similar experience (loss ratios at manual rates) regardless of the size of the risk. We have recalculated the experience rating modification factors for policy year 1988 for all experience rated risks in four test states, using expected losses adjusted as described above. The results are shown in the table below:

Table III - Average Experience Modification Factors

STATE	PRIOR EXPERIENCE RATING PLAN	REVISED EXPERIENCE RATING PLAN
Florida	.993	.995
Maine	1.037	1.023
Nebraska	1.011	1.016
Utah	1.011	1.020
AVERAGE	1.005	1.006

EXPERIENCE RATING PLAN

These experience modification factors are based on the experience in policy years 1984, 1985, and 1986. Each risk's experience modification factor is weighted by 1988 expected losses to produce the average experience modification factors.

Expected losses have been adjusted so that, in the aggregate, actual losses are equal to expected losses. Expected primary losses contain a similar adjustment. These adjustments are equivalent to the assumption that ELR's and D-ratios are accurate in predicting the true expected loss levels of experience rated risks as a group during the experience period.

These data indicate that if ELR's and D-ratios were on average correct for experience rated risks, the off-balance of the plan would be small. If the ELR's and D-ratios were appropriate for all risks, but not for experience rated risks by themselves, the average experience modification factors could differ from 1.0 by larger amounts. This difference would be due to the potential differences between the loss ratios of risks of different sizes, randomness, and the tempering impact of credibility.

We believe that the calculation of ELR's and D-ratios will produce expected losses and expected primary losses that are reasonably accurate, provided the current calculation is modified as recommended in this report.

To summarize, these suggested modifications are as follows:

1. Adjust the trend removal factor to correctly reflect the differential impact of medical trend applied to each of the industry groups.
2. Do not use the assumption that expected ultimate losses are uniformly distributed by policy year to calculate law amendment and loss development removal factors. Rather, calculate or approximate the actual distribution of expected ultimate losses.
3. Use the individual class distributions of serious, non-serious and medical losses to calculate loss development and law amendment removal factors to calculate the ELR factor for each class.
4. Eliminate the off-balance adjustment factor of 1.01.
5. Adjust the D-ratio calculation to use three years of statistical plan data at first, second and third report in place of the single year at first report used currently.

EXPERIENCE RATING PLAN

6. Adjust the D-ratio calculation to reflect limited expected losses in the denominator.

It is likely that these changes will cause a change in the off-balance of the experience rating plan. The average change in the off-balance due to a change in the calculation of ELR's and D-ratios should be evaluated. Manual rates (and ELR's) should be adjusted by a factor to reflect the new off-balance in such a manner that standard premium is unaffected by the change.

Exhibit 5 shows the average experience modification factors for experience rated risks in each of the NCCI states from 1983 through 1990. An average is shown reflecting the premium weighted average of these factors. The average for the more recent years is slightly lower than 1.0. In 1983, the intrastate average was significantly less than 1.0. We conclude, that on average, the experience rating plan is roughly balanced.

The magnitudes of the average experience modification factors in some states, and the changes in these factors, (e.g., Louisiana, Maine, Oklahoma, Tennessee) indicate the need to closely monitor the changes in average experience modification factors over time.

Off-balances can exist due to randomness in the experience of the collection of risks evaluated, differences in manual loss ratios by size of risk, inaccuracies in the calculation of ELR's and D-ratios, and ELR's and D-ratios that have become out of date. We believe that the known inaccuracies in the calculation of ELR's and D-ratios should be corrected, and that NCCI should make every effort to keep ELR's, D-ratios, and manual rates up to date.

If risk experience as measured by loss ratios at manual rates differs systematically among risks of various sizes, this should be evaluated and reflected directly in the manual rating structure. Because the actual experience of each individual risk receives only partial credibility, the experience rating plan cannot correct for any known biases in manual rates.

Note that some differences in manual loss ratios that cannot practically be identified or corrected by the manual rating structure may exist among groups of risks. In this circumstance, the experience modification factor will reflect some of this difference. If systematic differences among risks exist, but cannot be identified and corrected in the manual rating structure, then we believe that such differences should be allowed to be manifested in each individual risk's experience modification factor.

EXPERIENCE RATING PLAN

The average experience modification factor should be examined over time and by state by NCCI. If significant non-random off-balances are observed, NCCI should attempt to determine the cause. Significant non-random off-balances are an indication that an additional rating variable exists that is not currently reflected in the existing pricing structure (assuming that ELR's and D-ratios are accurate). NCCI should attempt to identify these additional rating variables (if any) and directly incorporate them into the manual rating structure, if practical.

EXPERIENCE RATING PLAN

V. ANALYSIS OF PRIMARY AND EXCESS CREDIBILITY FORMULAS

Primary and excess credibility are functions of the employers' expected losses and the state (or states for interstate ratings). These credibilities have a significant impact on the results of the ERP and are the most important aspects of the plan that were changed with the RERP. In our analysis described below, we address the actuarial aspects of the experience modification formulas and credibility formulas developed by NCCI.

The first question addressed is whether NCCI formulas are theoretically sound. As discussed in Section C.2., the answer to this question depends on whether actual historic primary losses are predictive of future excess losses. We developed and applied a number of tests of the predictive value of the primary losses. The results of these tests are discussed in Section D.1. In addition we recommended and tested an adjustment to NCCI formulas to account for the relationship between primary and excess losses.

The second question addressed is the selection of parameters once a set of formulas has been chosen. In Section C.3. we discuss a procedure for selecting parameters which provide the best fit to a given set of data. In that same section we also discuss a retrospective test to determine how well a set of parameters has performed. In Section D.2. we apply those tests to determine how well the RERP parameters perform on the data from a sample of states.

A. Description of Data Used in Our Study

Our analysis is based on individual risk data supplied to us by NCCI for the following six states:

- Florida
- Colorado
- Illinois
- Maine
- Nebraska
- Utah

These states were selected by M&R in order to provide a representative sample of state characteristics, including size.

EXPERIENCE RATING PLAN

For all six states the following information was provided by risk, by policy year, and by class:

- Risk ID
- Effective Date
- Class Code
- Hazard Group
- Payroll
- Expected Losses
- Expected Primary Losses
- Actual Losses split into 6 layers by size of claim
- PERP Primary Losses

This information was provided for the most recent six available policy years by combining information from several NCCI files. For all policy years the calculation of expected losses was based on the Expected Loss Rates (ELR's) and D-Ratios calculated by NCCI and contained in the most recently approved rate filing.

B. Data Adjustments and Segmentation

The data described in Section A was used by Milliman & Robertson to produce a data base which showed the following information for each risk, for each policy year:

1. Actual total rateable losses (rateable losses are those losses used in the experience modification formula, e.g., after individual claim limitations)
2. Expected total rateable losses
3. Actual losses limited to \$5,000 per claim (primary under the RERP definition)
4. Expected primary losses (total expected losses x D-ratio)

For all states except Florida, three policy years of data were reviewed. Five policy years of data were reviewed for Florida. Risks with fewer than three policy years of data were excluded.

EXPERIENCE RATING PLAN

In addition to excluding risks with fewer than three years of data, a small number of risks were excluded because the data reported for them was considered either unreliable or unrepresentative. These consist of risks with no expected loss for a given year or negative dollar amounts.

The ratio of actual to expected losses ("loss ratio") was calculated for each risk and year. This calculation was done separately for total losses, primary losses, and excess losses (total minus primary). In order to adjust for trend, loss development or benefit change factors by year, the loss ratios were normalized by dividing by the statewide average for each year.

The risks in each state were then divided into five groups based on their size. These groups or "risk size ranges" were based on the total expected losses for the risk for the sum of the three policy years reviewed. As shown in Exhibit 6, the size ranges were selected to include the same number of risks in each range. Exhibit 6 also shows the average expected losses for each size range.

C. Description of Methodology

1. The Use of Regression to Estimate Credibility

A basic premise of an experience rating plan is that an individual risk's historical loss experience has some predictive value in projecting its future experience. In this analysis, one approach we used to evaluate the predictive value, or credibility, of historical losses was to measure the relationship between a risk's loss ratio (actual/expected losses) in one year and the same risk's loss ratio in another year or years. The relationship between years was based on a linear regression. Although these calculations are described in detail below, an example may clarify the basic approach.

Exhibit 11, Sheet 1 is a graph based on individual risk data for relatively large risks in Florida. To prepare this graph, we first adjusted and sorted the data for individual risks as follows:

- a. We "normalized" the expected loss ratios for individual risks so that the aggregate loss ratio (actual/expected losses) was equal to 1.00 for each of the policy years.

EXPERIENCE RATING PLAN

- b. We sorted the data by total expected losses. After sorting, we divided the risks into five size groups, where each group contained the same number of risks. Exhibit 11 presents the data from the Florida size group containing the risks with the largest amount of expected losses.
- c. Within each size group, we sorted the data by the risk's primary loss ratio for the first year in the experience period and divided the risks into ten subgroups, with approximately the same number of risks in each subgroup.
- d. The graph in Exhibit 11 shows the relationship between the average Year 1 primary loss ratio for each subgroup, and the average primary loss ratio for Year 2 for the same risks.

The fact that the graphs slope upward to the right is an indication that there is a positive correlation between the loss ratios for individual risks in Years 1 and 2. As a result, observing a risk's loss ratio in year 1 provides information about that risk's loss ratio in year 2. If a straight line is fitted to the data values on the graph, the slope of the line can be interpreted as the credibility of the loss ratio data from Year 1. In fact, as shown in the following equations, the slope of the regression line represents the credibility factor which minimizes the squared error between the experience modification and the actual subsequent period loss ratio.

Years 1 through 5 are, respectively, 1986,..., 1982. In the linear regression tests, we generally treated the more recent year(s) as the independent variable and the older year as the dependent variable. The expected value of the resulting credibility estimate is the same, regardless of whether the older or newer year is treated as the independent variable in the regression.

- LR₁ = The actual loss ratio in period 1
LR₂ = The actual loss ratio in period 2
M = The experience modification (i.e., the projected loss ratio in period 2)
Z = The credibility factor

Under the RERP, the experience modification for both primary and excess losses can be written as:

$$M = Z \times LR_1 + (1-Z) \times 1$$

EXPERIENCE RATING PLAN

Minimizing the squared projection error requires that the following sum across all risks be minimized:

$$\sum(LR_2 - M)^2 = \sum(LR_2 - Z \times LR_1 - 1 + Z)^2 = \sum[(LR_2 - 1) - Z(LR_1 - 1)]^2$$

To determine the Z which minimizes this expression, we set the derivative with respect to Z equal to 0:

$$d \{ \sum (LR_2 - M)^2 \} / dZ = 2 \sum \{ [(LR_2 - 1) - Z(LR_1 - 1)] \times (LR_1 - 1) \} = 0$$

Solving for Z produces the expression:

$$Z = \sum [(LR_2 - 1)(LR_1 - 1)] / \sum (LR_1 - 1)^2$$

The expression for the slope of a linear regression between LR1 and LR2 is:

$$\text{Slope} = \sum [(LR_2 - LR_{2avg})(LR_1 - LR_{1avg})] / \sum (LR_1 - LR_{1avg})^2$$

For normalized data $LR_{1avg} = LR_{2avg} = 1$.³ Thus the slope of the regression line equals the credibility factor which minimizes the sum of the squared prediction error.

Hence the average primary credibility of one year's losses for each size group was directly measured by the slopes on graphs prepared in the manner described above. A similar calculation was done to estimate the credibility for excess losses.

The calculations described above yield primary and excess credibilities which produce the "best" (i.e., the minimum squared error) estimates of primary and excess losses when these estimates are calculated separately. However, as shown in Section C.2, the sum of these estimates may not produce the best estimate of total losses. If primary losses are positively correlated with excess losses, simply adding the above estimate of primary losses to that of excess losses would give too little weight to primary losses. In that case it would be more accurate to estimate total losses based on a modification formula like the Alternate Formula described in Section III.G. Section C.2. discusses this issue more fully and describes the methods which we used to test the relationship between primary and excess losses.

³ In this analysis, loss ratios were normalized by year but not by size range within year. As a result, LR_{1avg} and LR_{2avg} differed slightly from 1.

EXPERIENCE RATING PLAN

The graphs and the calculations described above were performed separately for primary and excess loss ratios, for each of the five risk size ranges described above.

Regressions were performed on the following combinations of years.

- a. Year 2 against Year 1
- b. Year 3 against Year 1
- c. Year 3 against the average of Years 1 and 2

For Florida, where data with sufficient volume were available, we also performed regressions on:

- d. Year 4 against Year 1

Exhibit 11, Sheets 2-6 summarize the results of our analysis for the five states we studied. The credibility values in Exhibit 11 have been adjusted to the bases of one, two and three years of experience, although the results were obtained from comparisons of either 1 or 2 years to a third year. These adjustments were made using the following formula:

$$\text{Credibility} = \text{Expected Loss} / [\text{Expected Loss} + k]$$

Credibility is computed by the method described above, using, for example, a comparison of data from years 1 and 2. The k term is then computed from the above formula. Given k and given the approximation that n years of losses equal n times one year of losses, credibility is computed for n (equal to 2 or 3) years of losses.

2. Correlation Between Primary and Excess Losses

If primary and excess losses were unrelated, the regression-based credibilities described in C.1 would minimize the squared error between the actual losses in the prospective period and the projected losses. However the goal in experience rating is to estimate the total losses for the prospective period given the risk's losses in the experience period. As a result, to the extent that the actual primary losses are predictive of future excess losses, they should be incorporated in the excess loss projection.

Intuitively, it seems reasonable to assume that actual primary losses are, in fact, predictive of future excess losses (on average). Primary losses can be thought of as a measure of a risk's claim frequency while excess losses are a measure of its claim severity. A primary

EXPERIENCE RATING PLAN

modification of, for example, 2.00 suggests that the risk's claim frequency is twice the average frequency contemplated in the manual rate. If excess losses for that risk were too erratic to provide any predictive information (i.e., excess credibility = 0), we should project that the risk's claim severity will be average. However, an average severity combined with a frequency twice the average, results in excess losses twice the average (i.e., excess modification of 2.00).

The modification formula used in the RERP determines the excess modification as a function of excess credibility and actual excess losses. Therefore, for the risk described above, the RERP would project that future excess losses will be average (excess modification = 1.00). Given that frequency for this risk is twice the average, the RERP projection would be accurate only if claim severity were unusually low. The actual excess experience for this risk provides no evidence of unusually low severity. As a result, the RERP is likely to do a poor job of projecting the excess portion of total losses for this risk. Since excess losses represent the majority of total losses (approximately 70%), this is potentially a significant problem.

The following example illustrates the alternate formula we are recommending in order to address this issue.

$$\begin{aligned} \text{D-ratio} &= \text{Primary Losses/Total Losses} = 30\% \\ Z_p &= \text{Primary Credibility} = 50\% \\ Z_e &= \text{Excess Credibility} = 5\% \\ A_p/E_p &= \text{Actual Primary Loss Ratio in Experience Period} = 2.0 \\ A_e/E_e &= \text{Actual Excess Loss Ratio in Experience Period} = 2.0 \end{aligned}$$

$$\begin{aligned} \text{Primary Modification} &= 2.0 \times 50\% + 1.0 \times 50\% = 1.50 \\ \text{Excess Modification} &= 2.0 \times 5\% + 1.0 \times 95\% = 1.05 \end{aligned}$$

$$\text{Total Modification (RERP)} = 1.50 \times 30\% + 1.05 \times 70\% = 1.185$$

Because of the low credibility of actual excess losses, the RERP projection of future excess losses (1.05) is based almost entirely on the manual rate. If primary and excess losses were related this would be a poor estimate since primary losses (which have a fairly high credibility) indicate that this risk is significantly worse than average. This problem is compounded because the RERP total modification formula gives 70% weight to the projection of excess losses. As a result, the RERP would project that this risk is only 18.5% worse than average.

EXPERIENCE RATING PLAN

A way to correct this is to replace the RERP modification formula with the following Alternate Formula which reflects actual primary losses in projecting excess losses.

Alternate Formula

$$\text{Primary Modification} = 2.0 \times 50\% + 1.0 \times 50\% = 1.50$$

$$\text{Excess Modification} = 2.0 \times 5\% + 1.5 \times 95\% = 1.53$$

(Note that the 1.5 used in the excess modification formula is the primary modification used in estimating expected excess losses).

$$\text{Total Modification (ALT)} = 1.50 \times 30\% + 1.53 \times 70\% = 1.52$$

Under the Alternate Formula, the total modification reflects the fact that the credible primary losses and the erratic excess losses indicate that this risk is significantly worse than average. In fact the total modification is only slightly different from the primary modification, reflecting the fact that actual excess losses contribute very little information to our projection of total losses.

If excess losses are related to primary losses (as we believe to be the case), the RERP can be used to approximate the more accurate Alternate Formula results in total by using primary credibility factors which are larger than the regression-based factors. The resulting overstatement of the primary modification will then approximately offset the understatement of the excess modification. This is illustrated below:

$$Z_p' = 100\%$$

$$Z_e' = 15\%$$

$$\text{Primary Modification} = 2.0 \times 100\% + 1.0 \times 0\% = 2.00$$

$$\text{Excess Modification} = 2.0 \times 15\% + 1.0 \times 85\% = 1.15$$

$$\text{Total Modification (RERP)} = 2.00 \times 30\% + 1.15 \times 70\% = 1.41$$

The above example shows that if actual primary losses are predictive of future excess losses, the RERP modification can be made to more accurately measure a risk's departure from average if the primary credibility factors used are higher than those indicated by regression. We found that the NCCI's primary credibilities were indeed higher than the average credibilities indicated by regression results based on primary losses alone. Given the structure of the RERP formula, this is reasonable, since the higher primary credibilities are

EXPERIENCE RATING PLAN

indicative of the power of primary losses in predicting future excess losses. However, in the above example, even though the primary credibility was increased from 50% to 100%, the resulting modification was still not as high as that indicated by the Alternate Formula. In fact, in order to achieve an RERP total modification of 1.50 for this risk, without unduly increasing the credibility of erratic excess losses, primary credibility would have to be increased above 100%.

In general, the RERP primary credibility needed to make the RERP modification approximate the Alternate Formula modification is given by the following relationship:

$$Z_{p-RERP} = Z_{p-ALT} \times [1 - (1 - D\text{-ratio}) \times Z_e] / D\text{-ratio}$$

If Z_e is the same for both the RERP and the Alternate Formula⁴

From this relationship it can be seen that, for D-ratios less than 1.00, the primary credibility that will result in the most accurate modification factors under the RERP is always greater than that under the Alternate Formula. Further, the RERP primary credibility should be higher by an amount which is a function of the D-ratio. Since D-ratios vary significantly by class while credibility is independent of class, it is impossible to achieve the same accuracy with both the RERP and the Alternate Formula. If primary losses are predictive of excess losses, the Alternate Formula should be more accurate. If primary losses are not predictive of excess losses, the RERP should be more accurate.

In order to test whether primary losses are, in fact, predictive of excess losses we performed three tests. The first test involved the following regression performed on Florida data.

"X" = Primary loss ratio in Year 1

"Y" = Excess loss ratio in Year 2

This regression directly tests the implicit assumption of the RERP formula that only excess losses (not primary losses) in one year provide information about excess losses (on average)

⁴ If Z_e is allowed to vary, the relationship is $Z_{p-RERP} = Z_{p-ALT} \times [1 - (1-D) \times Z_{e-ALT}] / D + [(A_e - E_e) \times (Z_{e-ALT} - Z_{e-RERP})] / (A_p - E_p)$. In general, Z_{e-RERP} will be higher than Z_{e-ALT} because under the Alternate Formula, the complement of Z_e is being applied to a more accurate prediction of future excess losses. Therefore, it is likely that the adjustment term accounting for the difference in excess credibility will be small on an expected value basis.

EXPERIENCE RATING PLAN

in another year. A positive slope in this regression implies that low primary loss ratios in year 1 are associated with low excess loss ratios in year 2 and, conversely, high primary loss ratios are associated with high excess loss ratios. This would imply that primary losses should be given some credibility in projecting future excess losses.

The second test involved a slightly different regression performed on Florida data.

"X" = Primary loss ratio in Year 1

"Y" = Excess loss ratio in Year 2 / Primary loss ratio in Year 2

This regression goes a step further than the previous regression. Rather than testing for the existence of a relationship, this regression tests the nature of the relationship between primary and excess losses. If there is no slope in this regression, then that implies that the ratio of the average excess loss ratio to the average primary loss ratio is a constant regardless of the risk's loss ratios in the experience period. This multiplicative relationship would support the use of the primary modification factor to adjust expected excess losses.

The third test (which is discussed in more detail in Section C.3) involved a single regression performed on all of the data simultaneously. We used four sample states: Florida, Maine, Nebraska and Utah. This regression determined the parameters (including both primary and excess credibility) which minimized the sum of the squared differences between individual risks' actual and projected total losses in the prospective period. The projected losses were based on three years of experience ending one year before the beginning of the prospective period. Throughout the remainder of this report, credibility parameters obtained through a regression of this type will be referred to as "optimized parameters".

In order to test the relationship between primary and excess losses, we calculated optimized parameters for both the RERP and the Alternate modification formulas. If actual primary losses are predictive of excess losses we would expect to find that:

- a. The optimized Alternate formula performs better than the optimized RERP formula.
- b. The optimized RERP primary credibility factors are significantly higher than the regression-based credibilities.

The results of the tests are discussed in section D.

EXPERIENCE RATING PLAN

3. Parameter Optimization / Quintile Tests

In addition to estimating credibility factors through linear regressions performed separately by size group and by state, we estimated optimized credibility parameters based on non-linear regressions on all of the data simultaneously. Optimized parameters were calculated for the RERP and the Alternate Formula. In addition, optimized parameters were calculated to test the effect of changing the number of years in the experience period from 3 to 5 years and changing the current split point from \$5,000 to \$2,000 and \$10,000.

Plan performance is evaluated in Exhibit 7. This exhibit is divided into two sections, (a) and (b). Section (a) tests the performance of PERP, RERP and the Alternate formula on three stratifications of risk attributes. Risks are stratified by size of loss ratio in the experience period ("quintiles"), by size of expected losses, and by state. Examples of the calculations underlying Exhibit 7 are shown in Exhibit 7a, Sheet 13.

The quintiles test shows the power of the experience rating plan to equalize loss ratios regardless of underlying historical experience. The tests by size and by state look for biases that may result from the selection of a particular formula.

Section (b) tests the RERP and the Alternate formula with 5 years of data and with \$2,000 and \$10,000 primary split points using the "quintiles" stratification.

The RERP contains three parameters each for primary and excess credibility formulas that describe the shapes of these curves. In addition, there is a scale adjustment factor that varies by state. The credibility curves of RERP are as follows:

$$Z_p = [E + aG] / [Eb + cG]$$

and

$$Z_e = [E + xG] / [Ey + zG]$$

G = State scale adjustment factors, equal to state reference point(s) divided by 250,000.

a, b, c, x, y and z = parameters optimized

In the regressions, the dependent variable (left hand side) was the normalized future period actual to expected loss ratio. It was assumed that this value is a proxy for each risk's true relationship with the average. The independent variables (right hand side) were the

EXPERIENCE RATING PLAN

credibility parameters as applied to the risk's historical actual and expected primary and excess losses in the experience modification formula. The experience modification factor is the predictor of the future average experience of the risk as compared to average.

The form of the regression is a non-linear function of the parameters a , b , c , x , y , and z , which were optimized simultaneously. A non-linear regression was performed to minimize the weighted average squared difference between the normalized future period actual to expected loss ratio and the resulting experience modification factor.

We have used the same functional form for the credibilities of the Alternate Experience Rating Plan. The six parameters are optimized using the non-linear regression approach separately for RERP and the Alternate Plan. The resulting credibilities are graphed in Exhibit 12, Sheets 1 and 2.

The first step in the performance measures shown in Exhibit 7 is to divide the data into five "quintiles". This was done as follows:

- a. Within each state (Florida, Maine, Nebraska, and Utah) the risks were divided into eight equal size groups according to expected losses.
- b. A loss ratio (actual/expected losses) was calculated for each risk for the prospective period (policy year 1988). A similar loss ratio was calculated for the experience period (the sum of policy years 1984-1986). Both the prospective and the experience period loss ratios were normalized so that the average loss ratio for each period for each state was 1.00. In addition, a "modified" prospective period loss ratio was calculated for each risk, for each modification formula being tested. The modified loss ratio was calculated as the (actual prospective period losses) / (normalized expected losses x experience rating modification).
- c. The risks in each state and size group were then ranked according to their loss ratio in the experience period and arranged into quintiles. Thus, within each state and size group, we created five groupings, each containing approximately an equal number of risks. The first quintile included the 20% of risks with the lowest experience period loss ratios while the last quintile included the 20% of risks with the highest loss ratios.
- d. For the summary exhibits shown in Exhibit 7, the quintiles by state and size group were combined.

EXPERIENCE RATING PLAN

The first performance measure is shown in the upper third of each sheet of Exhibit 7. It shows the average modified loss ratio by quintile for each plan. For example, the second column of Exhibit 7, Sheet 1 shows the average manual loss ratio for each quintile. The manual loss ratio of .684 for the first quintile implies that the "best" 20% of risks, based on past loss ratios, have subsequent losses which are 68.4% of those anticipated in manual rates. Thus, if there were no experience rating plan, these risks would be overcharged by 46% ($1.00 / .684 - 1.00$) on average. The third column indicates that if manual expected losses are modified using the PERP, the overcharge for these risks decreases from 42% to 17% ($1.00 / .852 - 1.00$). A perfect plan would eliminate any under or overcharge. This would result in modified loss ratios of 1.000 for each quintile. The closer the modified loss ratios are to 1.000 the better the plan performance.

In comparing two plans using the modified loss ratio measure, the performance by quintile is more important than in total. The RERP clearly performs better by quintile, reducing the over or undercharge for four of the five quintiles.

The trend of the modified loss ratios across the quintiles is also meaningful. If the plan is over-responsive to historical experience (credibilities too high), the good risks of the experience period will receive experience rating modifications that are too low and the bad risks will receive modifications that are too high. If the plan is over-responsive, a downward trend in the modified loss ratios will result, when reviewed from the lowest to the highest quintile. Likewise, if the plan is under-responsive, an upward trend in the modified loss ratios will result.

As expected, the unmodified loss ratios indicate an upward trend. It indicates that the historical experience has credibility in predicting future loss ratios. Of the other plans shown in Sheet 1, only the PERP appears to exhibit a trend. In this case, it appears that there may be an upward trend, indicating a possible under-responsiveness.

The second performance measure is shown in the middle block of each sheet in Exhibit 7. This measure is a function of the modified loss ratio measure discussed above. This measure shows the squared error of the modified loss ratio for each plan multiplied by 10,000. Thus the 219 shown for the PERP for the first quintile is calculated as $[(.852-1.000)^2] \times 10,000$. If a plan did a perfect job of flattening the loss ratios by quintile, the total squared error for that plan would be zero. The better a plan performs, the closer the squared error will be to zero. This measure often provides the clearest comparison between plans.

EXPERIENCE RATING PLAN

The final statistic shown in Exhibit 7 is the mean squared prediction error for all risks within each quintile. This is calculated as the weighted average of the square of the actual subsequent period loss ratio (actual / normalized expected) minus the predicted normalized expected loss ratio (experience modification factor). This statistic measures the variation of a risk's actual losses in a year against the losses anticipated in that risk's modified rate. Even if the modified rate were exactly equal to the true expected loss for each risk, there would still be considerable variation in the risk's actual experience from year to year. As a result, all of the plans tested produce relatively small improvements in this statistic.

D. Test Results

1. RERP Formula Versus PERP Formula

The results in Exhibit 7a, Sheet 1 (which groups risks according to the experience period loss ratio) show that the RERP is clearly superior to the PERP. Looking at the top block of statistics, the future period manual loss ratios (second column) show a clear upward trend when risks are grouped by prior period loss ratio quintile (first column). This indicates that prior period losses are predictors of future period losses.

The results in Exhibit 7a, Sheet 2 (which groups risks by state) and Exhibit 7a, Sheet 3 and 4 (which groups risks by risk size) also indicate that the RERP performs better than the PERP.

The third column of each sheet shows the performance of the PERP experience rating formula. This formula flattens the manual basis loss ratios (moves them closer to 1.0), resulting in more equitable charges than if there were no experience rating plan. However, the adjusted loss ratios in the third column indicate a significant upward trend. This means that the PERP was under-responsive to the actual experience period losses. After applying the PERP modification factor, those risks with good experience in the historical period can be expected to have lower than average loss ratios (based on standard premiums) in the future period. Similarly, those risks with bad experience in the historical experience can be expected to have higher than average loss ratios in the future period. Thus, the average credibility values of the PERP are too low.

The fourth column shows the performance of the RERP experience rating formula. Here, the trend in modified loss ratios has essentially disappeared, indicating that the overall levels of credibility in the RERP are more appropriate than in the PERP.

EXPERIENCE RATING PLAN

The second block of statistics is based on the squared departure of each cell from the target of 1.0. Lower numbers indicate better results. The RERP significantly reduces these squared errors when compared to the manual rates. The RERP shows a clear improvement in this statistic over the PERP.

The third block of statistics shows the average squared difference (on a risk by risk basis) between actual and predicted (by the modification) loss ratios. The lower this statistic, the more accurately the modification predicts each individual risk's future period loss ratios. By this measure as well, the RERP outperforms the PERP. Not only does it result in more accurate premium for groups of risks (between quintile squared error test, above), but it produces more accurate premiums for individual risks.

2. RERP Formula Versus Alternate Formula

As discussed in Section C.2, we would expect the Alternate modification formula to perform better than the RERP if actual primary losses are predictive of future excess losses. In that Section we described three tests designed to determine whether that relationship between primary and excess losses actually existed in the data for the states we reviewed.

The results of the first test are shown in Exhibit 8. This test involves a regression of the primary loss ratio in Year 1 against the excess loss ratio in Year 2. Although the excess loss ratios are erratic, it is clear from the graphs in Exhibit 8 that there is a relationship between the average primary and excess loss ratios.

The results of the second test are summarized in Exhibit 9. In this test, the primary loss ratio in year 1 for each size group is regressed against the ratio of the excess loss ratio in year 2 to the primary loss ratio in year 2. For all five size groups, the indicated slope for this regression differs from zero by less than one standard deviation. This suggests that the excess/primary ratio in year 2 is independent of the primary losses in year 1. In other words, the actual primary loss ratio in year 1 does as good a job of predicting the expected excess loss ratio in year 2 as it does of predicting the expected primary loss ratio in year 2. Based on this test, it appears appropriate to use the primary modification factor to adjust expected excess losses.

The results of the third test are summarized in Exhibit 7a. This test compares the performance of the optimized RERP with that of the Alternate formula. Because both plans are optimized based on the same data base (four states), differences between performance reflect differences between the plans themselves. The measures of plan performance used

EXPERIENCE RATING PLAN

are the three measures described in Section C.3. The statistics shown in pages 1 through 4 of Exhibit 7a indicate that the Alternate formula does, in fact perform better, although the degree of improvement over the RERP is unclear. The most important statistics in Exhibit 7a, in our view, are:

The mean squared error of the individual risk loss ratios (the all groups result, which is the same in all sheets of Exhibit 7a because it is independent of how risks are grouped). As noted previously in section C3, this statistic includes the random variation in actual individual risk losses, which causes the differences among the various experience rating formulas to appear small. It shows some improvement in going from the optimized RERP to the Alternate formula, but this improvement is smaller than that between the PERP and the RERP.

The between quintile squared errors in sheet 1. This measure shows better results for the Alternate formula than the RERP. However, when the risks are subdivided into eight size groups (sheets 5 through 12) the results do not clearly favor either the RERP or the Alternate formula. This may be due to random variation or could indicate that the Alternate formula does not improve accuracy for all risk sizes.

Each of these measures shows that the Alternate formula does, in fact, perform better than the RERP.

In Section C.2 we showed that if past primary losses are predictive of future excess losses, the credibility factors used in the RERP would have to be artificially high to offset the fact that primary losses are not used to adjust excess expected losses. As shown in Exhibit 12, this is in fact the case. That exhibit compares the primary credibility factors based on regression with those from the optimized RERP and Alternate plans. While the regression-based credibilities and Alternate plan are very similar, the RERP primary credibilities are significantly higher.

Based on the three tests discussed above, we believe that the Alternate formula can be expected to produce more accurate results than the RERP (or a version of the RERP in which the parameters have been optimized as in the Alternate formula). However, the degree of improvement is not clear. We recommend that further testing be done by NCCI using more states and more time periods to evaluate the degree of improvement produced by the Alternate formula. If the degree of improvement is found to be substantial, then we

EXPERIENCE RATING PLAN

would recommend implementing the Alternate formula as soon as is practical. If the improvement is found to be minor, then the practical difficulties involved in implementing a change in the formula make it appropriate to postpone implementation until such time as other significant changes are being implemented, or possibly to forego implementation altogether. This will be a matter of professional judgment.

It should be noted that a change to the Alternate formula should not be expected to affect the total premium adequacy for all risks combined in a given state.

3. RERP Parameters Versus Optimized RERP Parameters

Exhibit 7a compares the performance of the current RERP with that of the optimized RERP. As expected, the optimized RERP performs better on the states that we reviewed. Since the quantity minimized in the optimization is the mean squared error of the individual loss ratios, the "All Groups" line of the third block of numbers in Exhibit 7a is certain to indicate better performance for the optimized RERP than the current RERP. In fact, on each of the three measures displayed in Exhibit 7a, Sheets 1-4 (i.e., when risks are grouped by the experience period loss ratio or by state or by risk size) the optimized RERP performs better than the RERP. We recommend that if NCCI does not replace the RERP with the Alternate Formula recommended above, that they recalculate RERP parameters which are optimized based on country-wide data, and use optimized parameters if they produce significantly more accurate results. Testing the accuracy of the parameters should be performed on a state by state basis. Anomalies by state should be explained and reconciled.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

VI. SPLIT BETWEEN PRIMARY AND EXCESS LOSSES

A. Introduction

In both the PERP and the RERP, a risk's losses are divided into primary and excess components. In both plans, less credibility is given to the risk's excess losses than to its primary losses. The plans differ, however, in the definition of primary and excess losses. The RERP is a "single split" plan with a split point of \$5,000. This means that the first \$5,000 of each loss is considered primary, whereas the portion, if any, of the loss above \$5,000 is considered excess. The PERP, on the other hand, is a "multi-split" plan. Under that type of plan the split between primary and excess is based on a formula rather than a fixed dollar amount. The portion allocated to primary under the PERP varies from as little as \$2,000 for small claims to as much as \$10,000 for large claims.

In this section we will evaluate the following questions:

- Is a split between primary and excess losses desirable (i.e., does it improve the accuracy of the plan)?
- Is \$5,000 an appropriate split point to use?
- How does a single split plan compare to alternatives?

B. Desirability of A Primary/Excess Split

A basic premise of the primary experience modification formula used by NCCI is that subsequent period loss ratios are a linear function of prior period loss ratios. A linear relationship would imply that the slope of the graph (and therefore the credibility) for large prior period loss ratios is the same as for small prior loss ratios. In other words, the predictive power of large loss ratios would be the same as that of small loss ratios.

It can be shown⁵ that this premise does not hold for many of the highly skewed loss distributions which are thought to apply to casualty claims. For these distributions, some

⁵ *Foundations of Casualty Actuarial Science*, Casualty Actuarial Society, 1990, p. 462.

EXPERIENCE RATING PLAN

portion of very bad claims experience is largely random and provides little information about the risk's future loss experience. As a result, the indicated credibility for large claims is less than for small claims. Given the relationship between regression and credibility developed in Section V.C.1, we would therefore expect a graph of subsequent period loss ratios to "flatten out" with the slope (credibility) at large prior loss ratios less than that at small prior loss ratios. Using a single straight line to project future loss ratios would tend to overestimate the loss ratios for risks that had unusually bad experience while understating those of risks with good experience.

One way to address this problem is to introduce a split point. The effect of a split point is to divide a risk's experience into two parts: the primary portion which has relatively high predictive value; and the excess portion which is largely random and has relatively low predictive value. Within each of these categories the relationship between subsequent and prior period loss ratios is assumed to be linear. While this will not be perfectly accurate in practice, introducing a split point significantly reduces the difference between the actual relationship and a linear relationship (the "linearization error" of the plan) and therefore increases the equity of the plan.

C. Selecting the Appropriate Split Point

Varying the level of the split point affects both primary and excess losses. However, because primary losses are given significantly more weight in experience rating, the following discussion will focus on the effect of changing the split point on primary losses.

Selecting the appropriate split point involves a trade-off. If the split point is set too high, the linearization error in the primary credibility will be increased. However, if the split point is set too low, information which might be useful in projecting a risk's future experience will be combined with excess losses and given little credibility.

However, assuming the appropriate adjustments are made to the credibility of primary and excess losses, small changes in the split point should have little impact on the quality of the plan.

The current NCCI plan uses a single split point of \$5,000. A subjective assessment of whether the \$5,000 split point should be raised can be made by judging how close those graphs are to linear. Based on that test, it appears that the \$5,000 split point works well

EXPERIENCE RATING PLAN

for the largest risk size ranges. Because the smaller risk size ranges show some linearization error, it would probably be inappropriate to significantly increase the split point.

A subjective assessment of whether the current split point should be reduced can be made by looking at the relative proportions of primary and excess losses. Using the \$5,000 split point, approximately 30% of total losses are classified as primary. If the split point were significantly reduced, that would potentially lead to an undesirably small percentage of losses to be given primary credibility.

Our conclusion from these subjective tests is that the \$5,000 split point should not be significantly increased or decreased. This conclusion is supported by a comparison of the performance of the optimized RERP plan using the current split point with that of optimized plans using \$2,000 and \$10,000 split points. Exhibit 7b, Sheets 1 and 2 summarize the results of that comparison. That comparison shows that significantly increasing or decreasing the split point results in a deterioration of the performance of the plan as measured by the tests discussed in Section C.3.

D. Alternatives to A Single Split Plan

There are a number of ways of reducing linearization error aside from employing a single split point. In general, however, alternates are either more complex or conceptually less intuitive than the single split plan. One alternative is the multi-split plan. Under this plan, losses are allocated between primary and excess based on a formula. As losses increase in size, a progressively larger portion is allocated to excess. While this approach has potential for increasing accuracy, it is more complex than the single split plan. The PERP is a multi-split plan.

A second alternative is to "transform" losses before using them in the experience modification formula. For example, the experience modification might be based on the logarithm of prior losses rather than the losses themselves. This would have the effect of reducing the impact of unusually bad experience. However, it would be more complex, making the plan more difficult to understand and to explain.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

VII. NUMBER OF YEARS OF EXPERIENCE TO BE USED

A. Introduction

Currently, NCCI uses three years of data in experience rating. Adding years would increase the quantity of data but would decrease the relevance of the data. At some point, the decreasing marginal value of adding one more year of data does not justify the added complication. The following section discusses the value of a five year plan relative to the current three year plan.

The impact on the accuracy of the plan is only one factor that should be considered in deciding whether to go to a five year plan. Another important consideration is the cost and difficulty of implementing such a change. There are a number of practical impediments to changing from a three to a five year plan. In Section C, we suggest an approach which will minimize those impediments.

B. Projected Impact on Plan Performance

The impact on plan accuracy of adding more years of data is primarily a function of two opposing factors. The first factor is simply that adding more years increases the size of the sample used to project each risk's future experience. As such, more weight can be given to the risk's own experience, projections of the risk's future experience are likely to be more accurate, and the plan's accuracy will be increased. If this were the only factor, it would be possible to directly estimate the impact of such a change on individual risk credibility. For example, all other things being equal, a risk with 33.3% credibility for three years of data would have 45.5% credibility if five years of data were used. Thus the weight given to the risk's own experience would increase by 37% ($45.5/33.3 - 1$). These figures are calculated using the relationship:

$$\text{Credibility} = (\# \text{ of Years}) / [(\# \text{ of Years}) + ("k")]$$

Where "k" is a constant.

EXPERIENCE RATING PLAN

Sample Calculation of Credibility Given "N" Years of Data *

	N=3	N=4	N=5
Example 1	33.3%	40.0%	45.5%
Example 2	50.0	57.1	62.5
Example 3	75.0	80.0	83.3

* Assuming each year is equal in size and relevance.

In practice, however, the increase in credibility due to more data is at least partially offset by the decreasing relevance of the progressively older data. This factor is more difficult to quantify. In order to estimate its impact we compared the credibilities indicated by four regressions performed on Florida data. The results of those regressions are summarized on Exhibit 10.

The regressions underlying Exhibit 10 relate the primary loss ratio in year 1 to those in years 2, 3, 4, and 5. (Year 1 corresponds to policy year 1986. Year 5 corresponds to policy year 1982). As year 1 is regressed against years further into the past it becomes progressively less relevant and therefore we would expect the resulting credibilities to decrease. This is, in fact, the pattern that emerges on Exhibit 10.

In order to determine which of the two offsetting factors (increasing credibility due to more data and decreasing credibility due to decreased relevance) is more important in practice, we compared the performance of an optimized five year plan with that of an optimized three year plan. The procedure for optimizing each plan was the same as that described in Section V.C.3. The performance of each optimized plan is summarized in Exhibit 7b, Sheet 3. Based on the results shown in that exhibit, the use of five years of experience improves the performance of the plan whether the RERP or the Alternate Formula modification is used.

It should be noted that the data used in our tests for the two additional years were at 3rd report, because NCCI does not currently validate individual risk data at 4th or 5th report. We consider it likely that similar test results (Exhibit 7b, Sheet 3) would be obtained based

EXPERIENCE RATING PLAN

on data at 4th and 5th report, if such data were available. However, the use of 3rd report data adds somewhat to the uncertainty of the test results.

From a theoretical perspective, the ideal approach would be to include as many years as are available, and to assign weights to the years in proportion to their reliability for projecting future losses. However, it might not be possible to determine the ideal weights with much accuracy, and the resulting ERP would be more complicated (e.g., development and trend factors would have to be reflected separately for each experience year) and more difficult for insureds to understand. It is not likely that this approach would be practical.

The ideal approach can, however, be useful as a theoretical benchmark against which to compare alternatives conceptually. The current three year plan gives no weight to the fourth and fifth most recent years, while a similar five year plan would give full weight to the fourth and fifth years. The ideal approach most likely falls between these two; i.e., it is likely that the fourth and fifth years should be given weights between zero and the weights implicit in the five year plan (roughly the same as the weight given to the third year, after considering the effects of trend, loss development and law amendments). Further, given the use of a single trend factor, loss development factor, etc. for all policy years combined in calculating ELRs, the single factor can provide a closer approximation for individual risks in the case of a three year plan than a five year plan, because the exposure volume for an individual risk can be growing or declining over time. This consideration was taken into account in the comparison of optimized plan results discussed above (Exhibit 7b, Sheet 3) by "normalizing" the expected loss ratio for all three or five years on a combined basis rather than year by year.

C. Costs Associated with Adding Fourth and Fifth Years

There would be substantial implementation costs as well as ongoing costs associated with the addition of a fourth and fifth year to the experience rating plan.

The implementation costs would include:

1. Research to verify or rebut the improvement in accuracy indicated by our study, and to determine the appropriate parameters for the revised experience rating plan (ELR's, D-ratios, and credibility formulas).
2. Revision of the experience rating manual, forms, and computer programs.

EXPERIENCE RATING PLAN

3. Education of the public as to how inclusion of the additional two years will increase accuracy. Many policyholders already question the appropriateness of using the oldest year in the current three year experience rating plan.

The main areas of ongoing additional cost would be:

1. Additional editing and correction of fourth and fifth reports would entail work by both NCCI and the insurance companies. Currently, the fourth and fifth reports are used for retrospective rating and, hence, those for retrospectively rated risks are probably more reliable than those for other risks. NCCI also uses the fourth and fifth report data in studying loss development for Excess Loss Factors and class rate relativities, and in research. However, the level of accuracy required on an individual risk basis is not as high for such analyses as for experience rating.
2. Accumulation of the additional unit reports in the experience rating files would increase costs and would slow the process significantly. Each unit report shows the changes from the prior report. NCCI stores each of these incremental reports rather than only the cumulative values. Only claims with changes are listed in a given unit report. Although fewer claims have changes in the fourth and fifth unit reports than in earlier unit reports, use of the fourth and fifth reports in experience rating would require storage of the preceding first, second and third reports for those policy years.
3. Computer usage required for experience rating would be increased because of the increased size of the experience rating files and because of the additional computations required.

D. Conclusions

Based on our test results, it appears likely that the accuracy of the experience rating plan would be improved by expanding the experience period to five years from the current three years. Further testing based on data from additional states and, preferably, using fourth and fifth report data for the two additional years should be done before deciding to go ahead with this change.

EXPERIENCE RATING PLAN

Inclusion of the fourth and fifth years of experience would entail significant implementation costs as well as substantial ongoing costs.

In addition to the impacts on accuracy and cost, extension of the experience rating plan to five years could affect the perception of the plan's reasonableness by policyholders. Some policyholders already consider it inappropriate to use data as old as the oldest year currently used in experience rating; the addition of two older years would exacerbate this perception.

Expansion of the experience period to five years might also affect the benefits of risk management perceived by some insureds. On one hand, it will take longer for an improvement or deterioration in actual claim experience to fully impact the experience rating calculations. On the other hand, temporarily good or bad experience will impact the rates for a longer time period. Our judgment is that these possible perceptions probably would have little or no impact on risk management practices.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

VIII. ADMINISTRATION OF THE EXPERIENCE RATING PLAN

In addition to reviewing the formulas used in the RERP for actuarial soundness, we have also reviewed the administration of the plan. Based on that review, we have reached the following conclusions:

1. The calculations described in Section III are performed by computer. We have reviewed a sample worksheet from the computer programs used by NCCI and have confirmed that the calculations in the sample were done correctly. The experience rating worksheet that we reviewed shows the data and describes the calculation. It is sent to the carrier of record and is made available to the insured and the agent/service representative. Thus, the experience rating calculations are ultimately reviewed by many parties, and unusual results are likely to be questioned and otherwise brought to the attention of NCCI.
2. The loss and payroll data used is collected from the insurer under the workers compensation statistical plan. The data contains losses valued by the insurers, and payrolls audited by insurers. Thus, there appear to be reasonable safeguards against the submission of false data by insureds to obtain lower premiums.
3. The data is routinely reviewed by NCCI for reasonableness. Unusual values are referred back to the reporting insurer for explanation. If an adequate explanation is not provided, the data is not included in the experience rating calculation. Part I of this Examination reviews the data checks and systems of NCCI that are relevant to experience rating.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

IX. PREMIUM IMPACT OF THE REVISED EXPERIENCE RATING PLAN

NCCI performs a test of the potential change in the premium that may be caused by the change to the RERP in each state for which such a change is proposed. The experience modification factors issued in 1986 and 1987 in each state were re-calculated using the revised formula. If the average experience modification factor for a given state was found to change in the same direction for both years by more than two percent, a special adjustment was made to ELR's to eliminate the change.

Based on the 1986 and 1987 results, 9 states showed a need to adjust ELR's in order to maintain the same average experience rating off-balance. The states and the adjustment factors that were multiplied by the ELR's are shown below:

Colorado	1.03
Oregon	1.03
Maine	1.04
Maryland	.95
Mississippi	1.02
Minnesota	1.03
Tennessee	1.10
Rhode Island	.98
Utah	.97

Table III in Section IV.F shows the average experience modification factors in the four test states after the expected losses for each risk in the experience rating period were adjusted so that the average ratio of actual to expected losses was 1.0. This adjustment of expected losses is comparable to the assumption that ELR's and D-ratios are accurate for average experience rated risks. A review of this table shows that the RERP increased the average experience modification factor in three of the four states and decreased it in one of the four states. On average, premium would have increased very slightly if no other changes were made.

Table III shows that if ELR's and D-ratios used in both the PERP and the RERP were accurate, the implementation of the RERP would not produce a significant premium impact. The slight change in the average modification noted above could easily be due to random differences in the type of loss by risk, rather than a fundamental change caused by the change in formula.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

X. TREATMENT OF MULTI-STATE RISKS

Multi-state risks that have exposures in one or more of the states with interstate experience rating plans are issued a single experience modification factor for all such states combined. Those multi-state insureds that also have operations in states that do not use interstate rating rules, have a separate experience modification factor based on only the experience in each of these states.

As mentioned in Section III.F, when interstate rating rules apply, the experience rating plan values for W and B (and hence the credibilities), are evaluated in each state using the total expected losses of the risk in all interstate rated states. The W and B values that are used for the risk are the average W and B values of the states involved, using the state expected losses as weights. In this manner, the experience rating plan reflects the credibility that results from the combined volume of expected losses in all states, while giving appropriate consideration to each state's credibility formula parameters.

The interstate experience rating rules allow the experience of large multi-state risks to be assigned much higher credibility than if the risk's experience in each state were individually rated. We believe that this increases the accuracy of the rating of most such risks.

The interstate experience rating rules may increase the potential for inaccurate experience modification factors in certain circumstances. If the exposure mix by state for an experience rated risk changes between the time of the experience period and the time the experience modification factor will be applied, then the experience in the states may be given inappropriate weight. One solution to this problem is to calculate an experience modification factor for each of the interstate rated states credibility values based on the combined volume in all interstate rated states. Each state's resulting modification factor could then be applied to the prospective manual premium generated in that state. Note that this is different from the current NCCI intrastate rating approach. The credibilities would still be based on the combined volume in all interstate rated states, but the weighting would be by the prospective period manual premiums, not by the historical period expected losses.

The advantage of the approach described above is that it accounts for differences in a risk's indicated modification by state. A potential disadvantage, however, is that it may result in too much credibility being given to states with relatively little volume in the experience period. This results from the fact that the credibilities are based on the combined volume in all states, and the weight given to a state's modification is based on the state's volume in

EXPERIENCE RATING PLAN

the prospective rather than the experience period. It is not clear whether this disadvantage is likely to outweigh the advantage of this method in practice. We, therefore, do not recommend that NCCI adopt this modification to their interstate rating rules.

EXPERIENCE RATING PLAN

XI. EXTENSION OF THE PLAN TO SMALL RISKS

Not every risk is eligible to be rated under the RERP. Eligibility is determined by a minimum manual premium which varies by state. The eligibility requirement effective April 1990 ranged from a \$2,000 annual premium for Kansas to a \$6,000 annual premium for Louisiana. Given an average ELR factor of approximately .30, this range corresponds to a range of approximately \$600 to \$1,800 in annual expected losses.

Currently, the majority of risks (approximately 75%) fall below the minimum premium for eligibility, and are therefore charged the manual rate irrespective of their actual historical experience. Extending the ERP to these risks would involve a significant increase in the amount of data which NCCI would need to maintain and process. One method of reflecting actual experience which does not involve extending the entire ERP, is to offer a credit for loss free experience.⁶ In order to maintain the balance of the plan, these credits would need to be offset by debits applied to the rates of all other small risks. In this section we discuss a methodology for calculating the indicated credits and debits for a three year experience period. This methodology is illustrated using data from the states we have reviewed.

We have calculated the indicated credit and debit for small risks in three steps. The first step is to estimate the percentage of small risks which are likely to be claim free during the experience period. The second step is to determine the credibility (and therefore the indicated credit) of claim free experience. The final step is to calculate a debit for risks with at least one claim in the experience period which, when offset against the credit given for claim free experience, leaves the plan in balance.

A. Probability of Claim Free Experience

NCCI does not maintain loss information by year for small risks. As a result, data was not available to directly calculate the probability of claim free experience for those risks. We have, therefore, approximated three years of experience for a small risk by observing one year of experience for risks for which data is available. One year of experience for

⁶ In the following discussion, a risk will be considered to have had a claim if it has incurred losses greater than zero as of the evaluation date. Thus, a risk which has had only claims which closed without payment would be considered claim free.

EXPERIENCE RATING PLAN

experience rated risks with annual expected losses of \$3,000 or less was used to develop estimates of the three year experience of smaller risks. The following is an illustration of the application of this method. If a claim free credit is implemented, we recommend that NCCI apply this method to estimate the probability of claim free experience.

The following table summarizes the experience of rated risks with annual expected losses of \$3,000 or less.

Table V - Experience Rated Risks with annual Expected Losses of \$3,000 and less

Policy Year	Average Expected Loss	Percent Claim Free During Year	Percent with One or More Claims
1982	1,783	39.4%	60.6%
1983	1,952	36.6	63.4
1984	1,945	37.6	62.4
1985	2,023	38.6	61.4
1986	1,987	43.1	56.9
1988	2,076	49.0	51.0
All	1,944	40.6	60.4

The states used for this review were Florida, Maine, Nebraska, and Utah.

These probabilities were then adjusted to reflect the average three year expected loss for small risks. As shown in Exhibit 14, Sheet 2, the average annual premium for small risks for policies incepting in the period October 1, 1987 - September 30, 1988 was \$963. Assuming an average ELRF of .30, the average three year expected loss for these risks is \$867 ($= \$963 \times .30 \times 3$). In order to compare this average to the \$1,944 average calculated above, an adjustment must be made to put the two figures on the same cost level. Since the \$1,944 average is based on the period from 1982-1988, while the \$867 average is based on data for 1987-1988, it is necessary to adjust for approximately 3.1

EXPERIENCE RATING PLAN

years of loss cost inflation⁷. If we assume that claim costs are trending at 10% per year, an \$867 average expected loss for 1987-1988 corresponds to a \$645 average 3.1 years earlier ($645 = 867 \times 1.10^{-3.1}$). A claim free probability of 40.6% for expected losses of \$1,944 corresponds to a claim free probability of approximately 74.2% ($= 40.6\% \times [645/1944]$) for expected losses of \$645. This represents the estimated probability that the average small risk will be claim free for three years.

B. Credibility of Claim Free Experience

If the Alternate Modification Formula described in Section III.C is adopted, the credit that would be given for claim free experience of small risks, if they were eligible for experience rating, is:

$$1-M = 1 - \frac{[(1-Z_p)E_p + (1-Z_e)E_e] \times M_p}{E}$$

Where

- M = The total premium modification
- M_p = The primary modification
- E = Total expected loss
- E_p = Expected primary loss
- E_e = Expected excess loss
- Z_p = Primary credibility
- Z_e = Excess credibility

Since Z_e = 0 for small risks and M_p = 1-Z_p this formula reduces to:

$$\begin{aligned} 1-M &= 1 - \frac{[(1-Z_p) \times (E_p + E_e)]}{E} \\ &= Z_p \end{aligned}$$

⁷ A further refinement that has not been made in this illustration would be to adjust for differences in the average cost levels by state.

EXPERIENCE RATING PLAN

Thus, under the Alternate Formula, the credit indicated for claim free experience for small risks is equal to their primary credibility.

As shown in Exhibit 13, the indicated three year primary credibility for the average sized small risk (using the optimized Alternate Formula) is 7.1%.

C. Debit for All Other Eligible Small Risks

If 74.2% of small risks with three years of available experience are given a credit of 7.1%, the remaining 25.8% of eligible small risks must pay more than the manual rate in order to maintain the balance of the plan.

The magnitude of the debit which balances a 7.1% credit depends on the ratio of the expected loss for claim free small risks to the expected loss for all small risks. Since the probability of being claim free varies inversely with the size of the risk, claim free risks will probably represent less than 74.2% of the total expected loss for small risks. For the sake of this example, we have estimated that claim free small risks account for 65.0% of the expected loss for all small risks. This estimate can be refined by obtaining the distribution of unrated risks by size.

Given that the claim free proportion of expected losses is 65.0%, the magnitude of the debit which balances a 7.1% credit is 13.2% ($= 7.1\% \times 65.0\% / 35.0\%$).

In order to maintain the balance of the plan, all eligible risks must participate. If participation were voluntary, risks that would receive a debit would withdraw from the plan resulting in a net credit to small risks.

A risk would be considered eligible if:

1. the risk failed to satisfy the minimum premium requirements for eligibility in the Experience Rating Plan, and
2. the risk had premium for at least three completed years.

EXPERIENCE RATING PLAN

D. Implementation

The following is a description of how the Claim Free Credit Plan (CFCP) would work in practice. The first three years a small risk is insured, it would not be eligible for the CFCP and would therefore be charged the manual rate irrespective of its actual loss experience. If that risk is claim free for those three years (we estimate that approximately three fourths will be), the following year it will receive a credit of 7.1%. The risk will continue to receive the 7.1% credit as long as it remains claim free. If the risk has a claim, it will receive 13.2% debits for the following three years, irrespective of its loss experience during those years.

As discussed above, this plan would be balanced in that the total credits given in a year are expected to be offset by the debits given. Balance is, however, only one consideration in evaluating a plan. Other considerations include the equity of the plan and the degree to which it encourages loss control.

With respect to equity, the CFCP improves the equity for the average small risk but may create significant inequities for individual risks. This is true for both risks receiving a debit as well as those receiving a credit. For example, consider a large unrated risk. The expected losses underlying the manual premium for this risk may reflect an expectation of one or more claims in three years. Nevertheless, if this risk's claim experience were as expected, it would receive a significant debit for having had a claim. In fact, if more than one claim is expected for this risk, it is possible that it will receive a debit even if its experience were better than expected. Clearly for this risk, the current system would be more equitable than the CFCP.

Inequities exist for very small risks as well. For these risks, the credibility of their actual experience (i.e. the degree to which it helps us project their future experience), is very low. The issue in this case is not whether a given risk deserves a debit. A single claim in three years is almost certainly worse than expected experience for very small risks. The issue for these risks is the magnitude of the modification. The CFCP is likely to produce too large a modification for risks significantly smaller than the average unrated risk. For example, consider a group of small unrated risks that are expected to have one claim in thirty years. If the manual premium is exactly accurate for each of these risks, it is likely that roughly one in ten will have a claim over any three year period. The remaining 90% will be claim free. In this case, both the claim free risks, as well as those that experienced a claim, deserve little, if any, modification to next year's manual premium. For risks this small, three years of experience may be too little data to make a credible distinction between a chance occurrence of a claim and one that reflects true differences in expected loss. The CFCP,

EXPERIENCE RATING PLAN

however, will give 10% of the risks fairly large debits (based on the credibility of the average sized unrated risk) and the remaining 90% credits. As a result, for these risks the current system of charging manual rates regardless of prior experience may be more equitable than the CFCP.

With respect to the goal of promoting loss control, the CFCP is somewhat superior to the current system. A disadvantage of the CFCP, however, is that it does not distinguish between a risk that had one small claim three years ago and one that has had a number of large claims in each of the last three years. As a result, risks whose loss control systems mitigate damages or minimize the number of claims get no benefit.

The equity and loss control incentive of the CFCP could be improved by using credits which vary by the risk's expected loss and debits which vary by both the risk's expected loss and the frequency and severity of its loss experience. Such a plan would, however, be considerably more complex and difficult to administer than the form of the CFCP described above.

We recommend against implementing a Claim Free Credit Plan of the type studied in this report, because of the inequities discussed above. Alternative approaches could reduce these inequities by varying the credits and surcharges according to the size of the risk and possibly according to the sizes of claims, but such a plan would be significantly more complicated and difficult to administer.

E. Conclusions

In this section, we have described and illustrated a method for reflecting claim free experience in the premium of small risks. Based on the data for the states we have reviewed, the indicated credit for a small risk with three years of claim free experience is approximately 7%. In order to balance that credit, eligible small risks with at least one claim in three years should be debited approximately 13%. If the decision is made to implement the CFCP, we recommend that NCCI estimate the indicated credits and debits using the method we have described (including the noted refinements).

A CFCP is a compromise between the equity and loss control incentive of a full experience rating plan and the ease of operation of the current system of manual rates for small risks. If introduced, the CFCP would improve the equity of the premium charged to average sized unrated risks (i.e., those not eligible for experience rating). It is, however, likely to

EXPERIENCE RATING PLAN

result in less equity than the current system for the largest and the smallest unrated risks. For large unrated risks (i.e., those close to but below the experience rating threshold) the CFCP may result in debits for risks whose experience is no worse than expected. For very small risks, the CFCP is likely to produce a larger swing in premium than is warranted by the credibility of actual experience. On average, the CFCP would cause unwarranted premium increases for large unrated risks and unwarranted decreases for the smallest risks.

We recommend against implementing a Claim Free Credit Plan of the type studied in this report, because of the inequities discussed above. Alternative approaches could reduce these inequities by varying the credits and surcharges according to the size of the risk and possibly according to the sizes of claims, but such a plan would be significantly more complicated and difficult to administer.

It should be noted that the credibility that would be assigned to the larger unrated risks, if they were eligible for experience rating, is high enough (see Exhibit 12) to suggest that experience rating would improve the accuracy of the rates for such risks. Our understanding is that NCCI has slowed the updating of eligibility requirements so that inflation will cause smaller risks to become eligible. We consider this appropriate.

EXPERIENCE RATING PLAN

EXPERIENCE RATING PLAN

XII. EXPERIENCE RATING PLAN OFF-BALANCE IMPACT ON RATEMAKING METHODOLOGY

A. Impact of Off-Balance on Overall Rate Change

Standard premiums are used by NCCI in the determination of overall rate level change indications. These premiums reflect the impact of experience modification factors. NCCI standard ratemaking formulas indicate how much the premiums after the impact of experience modification factors should change. Through the use of standard premiums in the ratemaking formula, the premium level change anticipates any systematic off-balance inherent in the experience rating plan.

For example, suppose a state has consistently had an off-balance of 1.10. That is, standard premiums are 10% above the premiums produced by manual rates. If a 5% premium level change is indicated, this means that standard premiums should increase by 5%. If the off-balance remains 1.10, and rates are increased by 5%, premiums will also increase by 5%. Thus, the actual level of experience rating off-balance is not important in determining the correct premium level change, provided that the off-balance remains constant over time.

Conceptually, there are two ways for a change in premium level to occur. A change in rates (and/or rules) will produce a change in premium, and a change in the average off-balance of the experience rating plan will also produce a change in premium. If the average off-balance of the experience rating plan remains constant or varies randomly around a constant level, then an indicated change in standard premium level can be achieved by an identical change in manual rates. This is the procedure used by NCCI in most circumstances. We agree that it is appropriate in most circumstances.

There are some circumstances in which the average off-balance has changed or is expected to change in a systematic way. Depending on the causes of the systematic changes, special adjustments may be needed to achieve the appropriate changes in premium level.

There are three main categories of potential causes of systematic changes in experience rating off-balance:

EXPERIENCE RATING PLAN

1. Changes in rules or calculations: Any change in experience rating rules, calculations of ELR's, D-Ratios, or credibility parameters, or the experience rating formula itself has the potential to affect the average off-balance in a systematic way.
2. Outdated ELR's and D-Ratios: If ELR's and D-Ratios are not updated regularly, they may no longer reflect the underlying loss costs in the experience rating periods for which they are used. Consequently, the average off-balance may change in a systematic manner. In general, NCCI updates the ELR's and D-Ratios whenever rates are revised. The updated ELR's and D-Ratios should normally be reasonably accurate, even in cases where NCCI and regulatory officials have disagreements regarding the rate changes themselves. The areas of disagreement (e.g., trend, loss development, expense levels, profit margin) usually have little impact on ELR's and D-Ratios.
3. Changes in the risks insured: The population of insured risks may change over time. This can cause the average experience modification factor to change as well. For example, larger risks with lower than average experience modification factors may have a greater tendency to opt for self-insurance. Consequently, if there is a trend toward self-insurance and all else remains constant, the average experience modification factor for the remaining risks will rise. Other non-random changes in the characteristics of the population of insured risks may cause changes in the average experience modification factor as well.

In categories 1 and 2, above, the change in off-balance would distort the overall rate change if no adjustment were made. If such a change occurred in the experience period used in estimating trend, the trend estimate would be distorted and should be recalculated to eliminate this distortion. Ideally, the loss ratios used in calculating the trend factor would be adjusted to reflect the future (or at least a common set of) experience rating plan rules and formulas (category 1) or appropriate ELR's and D-Ratios (category 2). Where that approach is not practical, it may be possible to restate the loss ratios used in the trend calculation at manual rates. The latter approach (using loss ratios based on manual premiums) is more susceptible to distortion by a shift in the mix of business (see discussion of category 3., below), but should generally provide a reasonable estimate of trend.

If the change described in category 1 occurs during or after the experience period used in ratemaking (usually one policy year and one accident year), then an explicit adjustment should be made to the proposed manual rates, so that the change in average off-balance will not result in an overall premium level that is inappropriately high or low.

EXPERIENCE RATING PLAN

If the situation described in category 2 affects the loss ratios in the experience period used in ratemaking, then those loss ratios should be adjusted to the approximate levels that would have occurred if appropriate ELR's and D-Ratios had been in effect in those periods. This would put the experience years on a basis more comparable with the prospective rating period, since appropriate ELR's and D-Ratios are presumably being proposed for the prospective rating period.

In category 3, above, the resulting change in off-balance represents a partial adjustment in standard premiums to reflect a larger change in loss costs. In effect, the experience rating calculations adjust the standard premiums so that the loss ratios used in ratemaking are affected less by the shift in mix of business than they would be if manual premiums were used in ratemaking. An analogy can be made to the classification rating system: a shift of business among classifications would cause the average classification differential (analogous to the average off-balance) to change, but would not distort the overall rate change. Experience rating does not fully reflect the change in the mix of business, because of the credibility factors, so it does not completely eliminate the change in loss ratios.

We do not consider a change in the ratemaking procedure to be needed when changes in off-balance occur as a result of the causes in category 3, for two reasons. First, it would rarely, if ever, be possible to measure the impact of such a change, separating it from random variations. Second, the trend factor automatically makes the appropriate adjustment to the projected loss ratios in cases where the change in mix of insureds occurs as a trend over a period of years.

B. Past NCCI Adjustments for Changes in Off-Balance

Category 1: Changes in the experience rating plan rules and/or calculations have occurred over the years. In some cases, NCCI has made an adjustment to manual rates to reflect the change in the average off-balance. Such an adjustment was made when NCCI expected the average off-balance to change due to a change in experience rating eligibility requirements. However, there have also been circumstances in which NCCI could reasonably expect a change in off-balance, but made no offsetting adjustment to manual rates.

For example, the calculation of ELR's described in Section IV of this report reflects a change in the trend removal factor that has been implemented within the past few years. Previously, in the calculation of ELR's, trend was removed from the manual rates to the

EXPERIENCE RATING PLAN

point where the ELR's were equivalent, from a trend perspective, to the statistical plan data underlying the classification relativity calculation. However, the experience rating plan experience period was normally later by one to two years. Thus, in periods of upward trends, the ELR's were underestimated. NCCI recognized this in the late 1980's and corrected the ELR calculation to properly reflect trend to the experience rating plan experience period. When this change was implemented, however, no off-setting adjustment was made to the rates. The change in the ELR calculation increased the expected losses used in experience rating, causing a decrease in the average experience modification factor (if all else were constant). Consequently, manual rates should have been simultaneously adjusted upward to maintain the same premium level. In some states where there were significant delays in updating rates and ELR's (which would compound the shortfall in premiums resulting from the trend removal change), the new procedure for trend removal was implemented gradually over a period of years to mitigate this impact.

Because the Revised Experience Rating Plan (RERP) was not expected to change the average off-balance, no separate adjustments to rates were made when the RERP was implemented. Individual state data was used to test whether a change in off-balance resulted from implementation of the RERP. If a significant change in off-balance was observed in the test, then NCCI made a special adjustment to the ELR's in that state to eliminate this change (discussed in greater detail in Section IX).

The changes in the experience rating system recommended in other sections of this report may cause changes in the average off-balance. When changes of this type occur, adjustments should be made in the ratemaking procedure so that the proper overall premium level change is achieved.

Category 2: In some states there have not been regular updates of ELR's and D-Ratios due to long time lags between approved rate changes. This situation is commonly accompanied by a large rate increase indication by NCCI. Since the upward trends in loss ratios are not reflected in increased ELR's and adjusted D-Ratios, it can be expected that the average experience rating off-balance will rise over time in such a state until a rate change is approved and ELR's and D-Ratios are updated. As discussed earlier, this will cause two distortions in the ratemaking procedure if no adjustments are made. First, the trend rate will tend to be understated, because the standard premiums underlying the most recent policy years' loss ratios will reflect higher average off-balances, resulting in lower loss ratios. (Note: these lower loss ratios could cause the trend rate to be overstated in filings in later years if ELR's and D-Ratios are then updated regularly.) Second, the average off-balance reflected in the latest policy year and accident year loss ratios, which are used in calculating

EXPERIENCE RATING PLAN

the overall rate change, will be higher than that expected for the period in which the proposed rates will be used, since ELR's and D-Ratios will be updated if the rates are revised. This too causes a tendency toward underestimation of rates. However, in this case the problem is not that the indicated premium level change is distorted but that the manual rates need to be increased by an even larger percentage in order to achieve the indicated premium level increase. This may be politically difficult, but it should be recognized that if no adjustment is made, the stated rate change will be greater than the actual premium level change. The stated rate change is the change that affects the risks that are too small to meet the eligibility requirements for experience rating. The reason such risks would need a larger rate increase is that, in effect, some increases would already have occurred on average for experience rated risks, because of the impact of their own experience on their rates, and this would have reduced the indicated overall rate change.

NCCI recognizes the potential for changes in off-balance when ELR's have become outdated. NCCI has sometimes, but not always, explicitly made adjustments to the ELR's that were otherwise calculated in order to reduce the changes in off-balance.

The special adjustments made by NCCI to ELR's in order to prevent or reduce large changes in off-balance are not the most accurate approach. If the new ELR's are known to be understated, the average experience modification factors will remain overstated. This preserves an inequity between experience rated risks and non-rated risks, as well as between large and small rated risks. It would be more accurate to allow the experience modification factors to decrease but to increase the manual rates (which, in turn, would affect the ELR's through the ELRF's) so that the correct overall premium change is achieved.

However, as noted previously, the bigger increases that would result for small risks may raise problems with public acceptance. In such cases, it may be appropriate to phase in the increases in ELR's and resulting decreases in average off-balance over time. However, it is important to keep track of the impact of this on average off-balances so that they do not result in a distorted picture of trends or loss ratios in subsequent filings.

C. Historical Trends in Off-Balances

Exhibit 5 shows the average experience rating modification factors for experience rated risks. On a countrywide average basis, the average modifications are reasonably close to

EXPERIENCE RATING PLAN

1.000 and do not appear to exhibit a significant trend. On an individual state basis, there are some significant differences from 1.000 and some significant trends.

Exhibit 16 shows the average annual change in the average off-balance over two five year periods, 1983 through 1987, and 1986 through 1990. These average changes were calculated for each of the states where we have average modification factors in Exhibit 5, Sheet 1. In Exhibit 5, the average modification factors for individual states only include intrastate ratable risks. Using the premium data in Exhibits 14 and 15, we have calculated the percentage of total premium accounted for by ratable (both intrastate and interstate) risks in each state. The average off-balance was approximated in each state by adjusting the average intrastate experience modification factor to reflect the percentage of premium that is ratable.

This will be an accurate approximation only if the average interstate experience modification is the same as the average intrastate experience modification. There is evidence, as shown in Exhibit 5, Sheet 1, that on a countrywide basis the average intrastate experience modifications are generally lower than the average intrastate experience modifications. However, since we are interested in examining changes in the average experience modification factors over time, we consider it unlikely that this approximation distorts the results observed.

Exhibit 16 shows that trends in average off-balance appear in many states. The earlier trend period, 1983 through 1987, shows that 10 out of 32 states had upward trends at the 5% significance level and no states had downward trends at the 5% level. If the data were truly random, we would expect to find approximately equal numbers of upward and downward trends, and only about 1 or 2 states with significant trends. The later trend period, 1986 through 1990, shows that 7 out of 33 states had significant trends; 4 of the 7 had upward trends and 3 had downward trends. While the numbers of upward and downward trends are about equal for this later period, there are still more states with significant trends than would normally result if the off-balances were truly random. Thus, there is statistical evidence of non-random influences on average experience rating off-balances (as could be expected based on the discussion in Section XII.B.).

EXPERIENCE RATING PLAN

D. Conclusions and Recommendations

Standard NCCI methodology does not address changes in experience rating off-balance, although adjustments have been made by NCCI in some cases. The implicit expectation is that if rate revisions are made on a timely basis (regardless of whether the full amount of the requested rate revision is granted), then off-balance movements should be relatively small and have insignificant effects on overall rate levels. As Exhibit 5 demonstrates, however, a number of states have experienced significant off-balance movements.

We recommend that standard NCCI methodology identify off-balance levels and movements during the experience periods used for trending and rate level indications. An attempt should be made to determine the cause of significant off-balance swings whenever they are seen.

Proper action in response to significant off-balance swings would be a function of the cause identified. We would recommend that adjustments not be made when changes are attributed to a change in the mix of risks which are insured. The situations in which we would often expect that adjustments would be appropriate include:

1. a change in the experience rating plan itself (e.g., rules, such as eligibility requirements, or formulas such as those for calculating ELR's) or
2. delays in updating ELR's and D-ratios, due to prior delays in the approval of rate changes.

In these cases, some distortion could be expected to occur (if no adjustments are made) in the overall rate change indication, through misestimation of the trend factor and/or through an inconsistency between the average off-balance underlying the latest policy year and accident year loss ratios and that likely in the future period for which rates are being estimated.

One or both of the above situations have occurred in recent years in many states. The trends observed in Exhibit 16 suggest that such situations have in fact caused distortions in several states. However, the data underlying Exhibit 16 excludes interstate risks, because their effect on individual state off-balances has not been compiled by NCCI. Interstate risks account for over half of the total premium volume.

EXPERIENCE RATING PLAN

We have recommended certain adjustments (Section XII.A) in the ratemaking procedure to eliminate these distortions. However, to implement those adjustments, it is necessary to develop data on the average off-balances on an individual state basis, including interstate risks.

We recommend that NCCI develop data on average off-balances on an individual state basis, including interstate risks, for all policy years and calendar/accident years used in a rate filing (including those underlying the trend calculation). This data is essential both for monitoring average off-balances (to help detect distortions) and for adjustments to correct for the distortions.

NCCI has sometimes included appropriate adjustments in its rate analysis, but often has not. In some cases, the adjustments made by NCCI were designed to reduce or eliminate a change in average off-balance (by adjusting the ELR's), while it would have been more accurate to allow the off-balance to change and to make an offsetting adjustment to the manual rates. If an adjustment is made to the ELR's in order to mitigate a change in average off-balance that would otherwise occur, this should be disclosed in the filing. It should be recognized that this type of adjustment represents a choice of stability in place of accuracy. Also, it is important to keep track of such adjustments and take them into account in subsequent rate analyses; if this is not done, they can result in a distorted view of trends or of experience loss ratios in subsequent filings.

Interstate³	.989	.950	.978	.988				
Countrywide⁴	.997	.970	.989	1.002				

¹ Ratable risks are those risks with experience modification factors. Note that 1986 and prior may include self-insured risks; 1987 and subsequent exclude self-insured risks.

² Sheet 2 of this exhibit shows the average factors before excluding self-insured Risks for 1983 to 1989. Removal of Self-Insured risks had a big impact for Tennessee. For the remaining states, the impact appears to be minor relative to the normal year to year fluctuations.

³ 1987 and subsequent weighted by expected losses; 1986 and prior weighted by premiums.

⁴ Intrastate and Interstate weighted by expected losses.

Notes:					
<ol style="list-style-type: none"> Subsequent Period Loss ratios are shown on a manual basis and after application of the experience modification factors calculated with several different formulas. Quintiles are based on the loss ratios of the experience period at manual rates. Manual refers to the loss ratio of the subsequent period on a manual rate basis. This is the NCCI Revised Plan with the credibility formulas re-calculated to minimize the sum of squared differences between modified loss ratios and 1.000. This is the NCCI Revised Plan adjusted to apply a primary experience modification to expected excess losses in the rating formula. Credibilities have been optimized to reflect this new formula. The sum of squared differences between the quintile loss ratios (first table) and 1.000 multiplied by 10,000. The mean squared difference between an individual risk's subsequent loss ratio at manual rates and its experience modification factor.

13. Loss Limitation Factor 1.000 - (12)	.852	.818	.735	.655

¹Calculation adapted from NCCI workpapers concerning 5/1/90 proposed Nebraska rate filing.

²The state average cost per case for all hazard groups combined is adjusted for each hazard group using countrywide differentials based on the latest 1st, 2nd, and 3rd reports of Statistical Plan Data.

³Excess ratios are the proportion of total (indemnity and medical) losses in excess of the loss limitation (1).

Interstate³	.989	.950	.978	.988				
Countrywide⁴	.997	.970	.989	1.002				

¹ Ratable risks are those risks with experience modification factors. Note that 1986 and prior may include self-insured risks; 1987 and subsequent exclude self-insured risks.

² Sheet 2 of this exhibit shows the average factors before excluding self-insured Risks for 1983 to 1989. Removal of Self-Insured risks had a big impact for Tennessee. For the remaining states, the impact appears to be minor relative to the normal year to year fluctuations.

³ 1987 and subsequent weighted by expected losses; 1986 and prior weighted by premiums.

⁴ Intrastate and Interstate weighted by expected losses.

Within Quintile - Mean Squared Errors of Individual Risk Loss Ratios⁷

Loss Ratio Quintile ²	Manual ³	PERP	RERP	Optimized RERP ⁴	Alternate Plan ⁵
First 20%	.520	.115	.168	.134	.128
Next 20%	.178	.065	.069	.065	.051
Middle 20%	.198	.146	.174	.166	.171
Next 20%	.127	.132	.142	.142	.150
Last 20%	1.570	.197	.240	.173	.195
All Groups	.555	.129	.154	.131	.134

Notes:

1. Subsequent Period Loss ratios are shown on a manual basis and after application of the experience modification factors calculated with several different formulas.
2. Quintiles are based on the loss ratios of the experience period at manual rates.
3. Manual refers to the loss ratio of the subsequent period on a manual rate basis.
4. This is the NCCI Revised Plan with the credibility formulas re-calculated to minimize the sum of squared differences between modified loss ratios and 1.000.
5. This is the NCCI Revised Plan adjusted to apply a primary experience modification to expected excess losses in the rating formula. Credibilities have been optimized to reflect this new formula.
6. The sum of squared differences between the quintile loss ratios (first table) and 1.000 multiplied by 10,000.
7. The mean squared difference between an individual risk's subsequent loss ratio at manual rates and its experience modification factor.

14. Loss Limitation Factors ⁸	.852	.818	.735	.655
15. ELR Factors (13) x (14)	.387	.371	.334	.297

¹Calculation adapted from NCCI workpapers concerning 5/1/90 proposed Nebraska filing.

²Premiums adjusted to 9/1/89 rate level, losses adjusted to 7/1/88 benefit level, developed to ultimate and trended to midpoint of proposed rates. Includes offset for change in minimum premium multiplier.

³Premiums adjusted to 9/1/89 rate level, losses adjusted to 7/1/88 benefit level and developed to ultimate.

⁴Midpoint of experience rating plan experience period.

⁵Inverse of weighted average of law amendment factors. Losses by injury type used as weights.

⁶Inverse of weighted case incurred development factors to ultimate. Development factors are those used in pure premium exhibits excluding the adjustment to policy year aggregate level. Weights are losses by serious, non-serious, and medical, after adjustment to 7/1/88 benefit level.

⁷Unweighted Average.

⁸From Exhibit 2.

CALCULATION OF LOSS LIMITATION FACTOR¹

	Hazard Group			
	<u>I</u>	<u>II</u>	<u>III</u>	<u>IV</u>
1. 10% of Proposed State Reference Point (Loss Limitation)	49,000	49,000	49,000	49,000
2. Average Fatal Cost ²	119,737	141,392	168,856	191,139
3. Ratio to Average for Fatal (1) / (2)	.41	.35	.29	.26
4. Excess Ratio for Fatal ³ (From Harwayne tables)	.683	.742	.801	.830
5. Average Perm Total Cost ²	184,818	216,698	224,500	282,912
6. Ratio to Average for Perm Total (1) / (5)	.27	.23	.22	.17
7. Excess Ratio for Perm Total ³ (From Harwayne Tables)	.821	.859	.868	.911
8. Average Major Perm Partial Cost ²	59,877	61,996	69,415	75,375
9. Ratio to Average for Major Perm Partial (1) / (8)	.82	.79	.71	.65
10. Excess Ratio for Perm Partial ³ (From Harwayne Tables)	.320	.334	.376	.411
11. (A) Fatal Weight Factor	.019	.028	.059	.115
(B) Perm Total Weight Factor	.024	.034	.043	.060
(C) Major P.P. Weight Factor	.361	.396	.481	.475
12. Weighted Average Excess Ratio	.148	.182	.265	.345
13. Loss Limitation Factor 1.000 - (12)	.852	.818	.735	.655

¹Calculation adapted from NCCI workpapers concerning 5/1/90 proposed Nebraska rate filing.

²The state average cost per case for all hazard groups combined is adjusted for each hazard group using countrywide differentials based on the latest 1st, 2nd, and 3rd reports of Statistical Plan Data.

³Excess ratios are the proportion of total (indemnity and medical) losses in excess of the loss limitation (1).

PRIOR EXPERIENCE RATING PLAN - LOSS LIMITATION FACTORS ¹				
STATE	HAZARD GROUPS			
	I	II	III	IV

Interstate³	.989	.950	.978	.988				
Countrywide⁴	.997	.970	.989	1.002				

¹ Ratable risks are those risks with experience modification factors. Note that 1986 and prior may include self-insured risks; 1987 and subsequent exclude self-insured risks.

² Sheet 2 of this exhibit shows the average factors before excluding self-insured Risks for 1983 to 1989. Removal of Self-Insured risks had a big impact for Tennessee. For the remaining states, the impact appears to be minor relative to the normal year to year fluctuations.

³ 1987 and subsequent weighted by expected losses; 1986 and prior weighted by premiums.

⁴ Intrastate and Interstate weighted by expected losses.

I. INTRODUCTION

As part of its examination of NCCI, the NAIC has requested that we review four miscellaneous areas.

- I. Objective (8a) - Compare the expected loss and expense ratios of minimum premium insureds to those for all classes of insureds combined. (Loss and Expense Ratios of Minimum Premium Insureds)
- II. Objective (8b) - What recognition does NCCI give to additional premium expected to be collected from surcharges imposed on policyholders in residual markets? As these markets increase or decrease, is this expected change in revenue recognized? (Residual Market Surcharges)
- III. Objective (8c) - Does the NCCI ratemaking formula accurately account for any off-balance due to the experience rating plan? Does NCCI adequately adjust expected loss rates (ELR) and "D" ratios to maintain off-balance at a reasonable level? What improvements could be made in NCCI's procedures? (Experience Rating Plan Off-Balance)
- IV. Objective (8d) - Test for any consistent tendency of the calendar/accident year loss ratio used in a rate filing to be higher or lower than the corresponding policy year loss ratio, after adjusting for trend. This objective was approved by the NAIC's Examination Oversight Group as an additional area of research. (Calendar/Accident Year vs. Policy Year Loss Ratios)

At the request of the Examination Oversight Group, the topic of Experience Rating Plan Off-Balance has been added to our report in Section IIB, Part 7 - Experience Rating. The other three topics will be covered here.

MISCELLANEOUS

II. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

Objective (8a) - Loss and Expense Ratios of Minimum Premium Insureds

1. Minimum premium risks appear to have consistently worse loss ratios than all other risks. These results are based on a comparison of losses to standard premiums excluding the expense constant. Due to the relatively small premium contribution from minimum premium risks and the size of the loss ratio differential, their effect on overall loss ratios is small. It is not clear what loss ratios will ultimately result from NCCI's current program of minimum premium multipliers. NCCI should continue to study the loss ratio experience of small risks. (Page 11)
2. Adequate data to study the expense experience of minimum premium risks is not available. However, based on data from the 1982 study of expenses by size of risk, the expense provisions for very small risks appear to be slightly greater than their expense needs. (Page 11)
3. If premium levels for minimum premium risks were increased, either through increasing the minimum premium multipliers or adding a loss constant, insurers might be more willing to provide voluntary coverage to these risks. On the other hand, there are a significant number of minimum premium risks and there is likely to be some dissatisfaction after a price increase targeted at minimum premium risks. Due to the low impact of minimum premium risks on the overall loss ratio, we believe that the policy of whether or not to change the pricing of minimum premium risks should be governed by its practical effects rather than its actuarial significance. (Page 11)
4. If the decision is made to adjust multipliers and maximum minimum premiums to the point that average rate levels for minimum premium risks contemplate reasonable profitability, then these factors, particularly the multipliers, will need to be determined by an analysis of loss experience for risks of minimum premium size. While countrywide experience would be appropriate to determine average multipliers for minimum premium risks, it must be noted that the amount of experience by state for minimum premium risks is often significant and the credibility of such experience would need to be explored. While we have compared the amount of minimum experience by state to the amount of experience available for classification ratemaking, it may well be the case that the credibility due minimum premium experience by state will be different from the indicated credibility due a comparable volume of classification ratemaking experience. (Pages 11-12)

MISCELLANEOUS

Objective (8b) - Residual Market Surcharges

In general, we believe that the standard NCCI procedures to reflect additional revenue from residual market policies are reasonable. However, we have a number of concerns regarding some related issues. These include: the potential future problem of double-counting adverse experience through a single set of experience modification plan parameters applied to both voluntary business and assigned risk business; the need to improve explanatory material in the rate filing; the need to reflect net premium programs in all states as a standard methodology; and, when data becomes available as to the collectability of ARRP premium surcharges, the need to replace the assumed 85% collectable percentage with a figure based on actual experience. (Pages 20-21)

Objective (8c) - Experience Rating Plan Off-Balance

At the request of the Examination Oversight Group, we have included the response to this objective in our report entitled Section IIB, Part 7 - Experience Rating.

Objective (8d) - Calendar/Accident Year vs. Policy Year Loss Ratios

In general, the policy year and accident year loss ratios used in recent rate filings appear to be reasonably consistent with each other. Calendar/Accident Year 1988 appears to be an exception. The difference appears to be caused by inconsistencies between policy years 1987 and 1988 and calendar year 1988 premiums. NCCI could not identify all of the causes of the apparent premium anomaly. This does not appear to be a problem with respect to 1991 filings which are based on calendar year 1989 and policy year 1988. However, we recommend that NCCI continue to investigate the reasons for the premium differences in those states where they are most pronounced. We also recommend that NCCI strengthen the process for editing carriers' calendar and policy year premium reports for consistency. (Pages 29-30)

MISCELLANEOUS

III. LOSS AND EXPENSE RATIOS OF MINIMUM PREMIUM INSUREDS

A. Background

NCCI calculates a minimum premium amount for each class in states where NCCI produces full manual rates. The minimum premium formula is:

$$\text{Minimum Premium} = \text{Rate} \times \text{Multiplier} + \text{Expense Constant}$$

In addition, there is a maximum minimum premium, which varies by state. Finally, the change in the multiplier is limited to 10 per revision (e.g., the multiplier can move from 35 to 45). The multiplier in the formula is targeted to be the annual payroll (in hundreds of dollars) of a single employee at the statewide average weekly wage. When the multiplier is increased, NCCI estimates the additional premium and offsets the manual rates to implement the change on a balanced basis. Exhibit 1 displays the historical minimum premium multiplier by state, as well as the maximum minimum premium and the expense constant.

B. Loss Ratios of Minimum Premium Insureds

1. Data Available

In order to research the loss experience of minimum premium risks, NCCI provided us with the following data for each state separately for minimum premium risks and all other risks:

- standard premium, excluding expense constants;
- risk count;
- losses (split by Medical and Indemnity).

This data was available for three separate policy years, but only at first report.

MISCELLANEOUS

2. Analysis

Based on data for the states we analyzed, minimum premium risks comprise approximately 0.3% of total standard premium for all states combined. Only two states, Iowa and South Dakota, had a percentage of premium greater than 1% over the three year period (see Exhibit 2). No state showed a percentage of premium greater than 2% in any year. This would imply that the credibility of minimum premium risk experience should be relatively small. However, later we will show that the relative premium volume of minimum premium risks is comparable to the premium volume of a large number of rate classifications.

On a risk count basis, minimum premium risks are more significant (see Exhibit 3). For policy years 10/1/85 and 10/1/86 minimum premium risks were approximately 8% of the total, while for policy year 10/1/84 minimum premium risks were 6% of the total for all states combined. (Note that these percentages are slightly understated on a countrywide basis. NCCI indicated that for a non-minimum premium risk, each state with premium was counted as one risk. Therefore, a two-state risk would register two policy counts, one in each state.)

For policy year 10/1/86, the percentage of policy counts varies from a low of 0.34% for Montana to a high of 22.22% for Utah. Most states are in the 6-10% range.

3. Loss Ratios

The minimum premium risks have higher loss ratios than all other risks. Table 1 shows the countrywide loss ratios at first report for minimum premium risks compared to all other risks:

Table 1

(1) <u>Policy Year</u>	(2) <u>Minimum Premium Loss Ratio</u>	(3) <u>All Other Loss Ratio</u>	(4) <u>Relativity (2)/(3)</u>
10/1/84	.620	.552	1.123
10/1/85	.751	.514	1.461
10/1/86	.783	.531	1.475

MISCELLANEOUS

The loss ratios are based on standard premium excluding the expense constant. This was done so that all risks, both minimum premium risks and all other risks have the same target cost ratio in each state. This table is derived from data in Exhibit 4.

However, the loss ratio relativities of minimum premium risks compared to all other risks vary substantially from state to state. For example, Iowa has a three year average relativity below the countrywide relativity while Alabama has a three year average relativity above the countrywide relativity (See Exhibit 4, Sheet 7).

In addition, the loss ratio relativities within state can vary substantially from year to year. For example, the District of Columbia shows two years where the minimum premium loss ratio relativities are less than 1.0 and one year with a loss ratio relativity well in excess of 1.0.

Table 1 indicated that the loss ratios of minimum premium risks are higher than all other risks on a countrywide basis. However, the effect of the minimum premium risks on the overall loss ratio is not significant, as demonstrated by Table 2:

Table 2

(1) <u>Policy Year</u>	(2) <u>Minimum Premium Loss Ratio</u>	(3) <u>All Other Loss Ratio</u>	(4) <u>Combined Loss Ratio</u>
10/1/84	.620	.552	.553
10/1/85	.751	.514	.515
10/1/86	.783	.531	.532

Our analysis here and in the following subsection is based on a comparison of premiums and losses at first report for minimum premium risks and all other risks. Therefore, an underlying assumption of this analysis is that the premiums are at comparable levels of accuracy including the effects of audits, and that losses for minimum premium risks will develop at rates similar to those of other risks. To the extent that these assumptions are not met, our conclusions would vary. This may represent a consideration for policy makers in making decisions that relate to pricing for small and minimum premium sized risks.

MISCELLANEOUS

C. Expected Loss Ratios of Minimum Premium Insureds

The premiums used in the analysis in III.B were earned premiums at collected levels. For both the minimum premium risks and the other risks, they reflect the manual rates in effect at the time the policy was written. For the minimum premium risks, they also reflect the minimum premium multipliers and maximum minimum premiums in effect at the time the policy was written. The minimum premium multipliers in the experience period were less than those based on the average weekly wage formula for all states.

To analyze the overall equity of the minimum premium, it would be appropriate to estimate loss ratio relativities for minimum premium risks if the minimum premium multipliers were at the level indicated by the formula. This is a complex task, since as multipliers are increased, small risks that were previously not minimum premium risks would become minimum premium risks. In addition, as the multiplier is increased, more risks would be subject to the maximum minimum premium. The maximum minimum premium is not tied directly to any index. Therefore, adjusting minimum premiums on level becomes a complex task.

As a first step in analyzing the equity of the current minimum premium program, we adjusted the minimum premiums at collected level by the ratio of the indicated multiplier (based on the statewide average weekly wage) and the actual multiplier in effect during the policy period. The results of this analysis for the policy year 10/1/86 to 9/30/87 appear in Exhibit 5.

It is important to realize that we have not reflected the impact of the maximum minimum premiums. This would make the adjusted minimum premiums smaller and the loss ratios larger. Exhibit 5 demonstrates that after our adjustments, the loss ratios of minimum premium risks are less than the loss ratios of all other risks. Note that both the minimum premium rates and the other than minimum premium rates are based on the manual rate level in effect when the policy was written. From Exhibit 5, we see that the adjusted minimum premium countrywide loss ratio is below the all other loss ratio. This, by itself does not mean that the current minimum premium program overcharges these risks. The actual minimum premium rates are the result of the total program which includes an indicated multiplier based on the average weekly wage, a maximum change in multiplier (currently 10), the maximum minimum premium and the change in maximum minimum premium (currently \$50 per revision, until a maximum of \$750 is reached). Limitations on changes in multipliers will restrict the movement towards the indicated multiplier. For example, we compared the last multiplier in effect for the policy year starting 10/86 with

MISCELLANEOUS

the indicated multiplier based on the average weekly wage. Then we assumed that multipliers would increase by 10 annually, while the average weekly wage would increase by 3% annually. Based on this scenario, after 10 years 3 out of 37 states had reached the indicated multiplier. After 15 years 6 out of 37 had reached the indicated multiplier. If we assumed a wage increase of 4% per year, then after 10 years and 15 years, only one state had reached the indicated multiplier.

The loss ratio experience of minimum premium insureds is worse than that of other insureds. However, determining the exact extent of the difference is a complex task. The use of a multiplier based on the annual wage of one average employee may over-react to the poorer loss ratio experience of minimum premium insureds. We recommend that NCCI continue the analysis of the relative loss ratio experience of small risks to ensure the reasonableness of the minimum premium program.

D. State Credibility of Minimum Premium Loss Experience

In order to examine the credibility of individual state minimum premium experience, we did not directly attempt to measure the credibility of the loss experience, due to the lack of extensive historical experience. Instead, we attempted to compare the statewide relative premium volume of all minimum premium risks combined to that of various rate classifications.

We proceeded as follows:

1. In our study of classification (Section IIB-Part 4), we obtained payroll information by class, for a number of states.
2. Using this payroll, we calculated a premium at present rates for each class.
3. For each state with data available, we sorted the classes by size of premium.
4. For each class, we calculated the percentage of total statewide premium volume which that class formed.
5. We then calculated the aggregate premium for all classes with individual premium less than a certain percentage of the statewide total. For example, in Connecticut, minimum premium risks formed .19% of the statewide total premium (see Exhibit 2, three

████████████████████

MISCELLANEOUS

year total). Thus, for Connecticut, we accumulated the aggregate premium for all classes that had premium less than .19% of the statewide total. We also counted the number of classes with non-zero premium that had less than .19% of the statewide total premium. Similar calculations were performed for the other states.

The results of this analysis appear in Exhibit 6. This exhibit shows, at least on an aggregate basis, that minimum premium risks have volumes comparable to a large number of classes. The aggregate premium volume of these classes is significant.

Therefore, at least on a premium volume basis, there appears to be no reason not to examine minimum premium experience on a statewide basis along with the classification review. However, the credibility resulting from a given volume of minimum premium experience may differ from the credibility due to a comparable volume of classification experience.

E. Expense Experience of Minimum Premium Insureds

1. Data Available

NCCI has not performed an analysis of expenses by size of risk since the 1982 study. (This study and the issue of expenses by size is discussed in Section IIB, Part 2 of our report.)

In the 1982 study, data was not separately categorized for minimum premium risks. However, based on the size categories that were analyzed, we have prepared an exhibit which shows the required general expenses by size and compares it to the general expense dollars generated by the provision in manual rates and the expense constant (see Exhibit 7). Although data for other acquisition expense was also collected, the manual rate provision does not separately isolate other acquisition expense from total production expense. Therefore, a comparison of required other acquisition with generated other acquisition is not possible. In the analysis that follows, we are treating risks less than \$300 in premium size in 1982 as a proxy for minimum premium risks. Assuming a 10% per year premium change, a \$300 policy in 1982 is equivalent to a \$400 policy in 1985, and a \$640 policy in 1990.

MISCELLANEOUS

2. Analysis

Based on the 1982 experience of all policies less than \$300, insurers incurred \$64.60 in general expenses per policy. The recommended general expense provision for those policies was \$70.12. This indicates a slight redundancy.

For the premium size interval \$200 - \$299, the 1982 experience indicates an expense deficiency, while for the two smaller premium size intervals (\$0 - \$99, and \$100 - \$199), the 1982 experience shows a redundancy. (See Exhibit 7).

F. Conclusions and Recommendations

1. Minimum premium risks appear to have consistently worse loss ratios than all other risks. Due to the relatively small premium contribution from minimum premium risks and the size of the loss ratio differential, their effect on overall loss ratios is small. It is not clear what loss ratios will ultimately result from NCCI's current program of minimum premium multipliers. NCCI should continue to study the loss ratio experience of small risks to ensure the reasonableness of the minimum premium program.
2. Adequate data to study the expense experience of minimum premium risks is not available. However, based on data from the 1982 study of expenses by size of risk, the general expense provision in the rates for very small risks appears to be slightly greater than the insurance companies' expenses necessary to handle these small risks.
3. If premium levels for minimum premium risks were increased, either through increasing the minimum premium multipliers or adding a loss constant, these minimum premium risks would be more desirable to insurers. On the other hand, there are a significant number of minimum premium risks and there is likely to be some dissatisfaction after a price increase targeted at minimum premium risks. Due to the low impact of minimum premium risks on the overall loss ratio, we believe that the policy of whether or not to change the pricing of minimum premium risks should be governed by its practical effects rather than its actuarial significance.
4. If the decision is made to adjust multipliers and maximum minimum premiums to the point that average rate levels for minimum premium risks contemplate reasonable profitability, then these factors, particularly the multipliers, will need to be determined by an analysis of loss experience for risks of minimum premium size. While countrywide

MISCELLANEOUS

experience would be appropriate to determine average multipliers for minimum premium risks, it must be noted that the amount of experience by state for minimum premium risks is often significant and the credibility of such experience would need to be explored. While we have compared the amount of minimum experience by state to the amount of experience available for classification ratemaking, it may well be the case that the credibility due minimum premium experience by state will be different from the indicated credibility due a comparable volume of classification ratemaking experience.

MISCELLANEOUS

IV. RESIDUAL MARKET SURCHARGES

A. Background

The residual market for workers compensation has been growing in most states. As residual market risks form a greater and greater percentage of the total market, increased attention has been focussed on how prices are determined for these risks. In addition, over the past several years, NCCI has introduced a number of new programs that serve to increase premium charges for some or all residual market risks.

However, programs to charge residual market risks rates that are different from voluntary risks are not new. According to NCCI, the first such program was introduced in Alaska on 1/1/82 when premium discounts were removed for risks in the residual market. Alaska then added a rate differential in 1984. Starting in 1987, NCCI began expanding these residual market programs with removal or reductions in premium discounts for residual market risks approved in Iowa and Kentucky, and a rate differential for a segment of the residual market introduced in Maine. In 1988, these programs began spreading more rapidly. Today, various programs have been filed and approved in virtually all NCCI states.

This Section will review following items:

- Identification of Residual Market Surcharge Programs;
- Ratemaking Adjustments for Residual Market Surcharge Programs;
- Estimating Rate Level Effects of Various Surcharge Programs;
- NCCI Concerns Regarding Net Premium Programs;
- Conclusions and Recommendations.

B. Identification of Residual Market Surcharge Programs

Exhibit 8 summarizes state residual market surcharge programs such as:

1. Removal of premium discount.

In states with this program, risks in the residual market receive no premium discount. However, a number of states have approved variations to this program, so that the discount

MISCELLANEOUS

will be reinstated in full for certain risks. For example, in Missouri, a residual market risk with an experience modification factor of 1.05 or less is entitled to premium discount. In Maine, only risks in the "Accident Prevention Account", (which is a subset of the residual market), lose their premium discount.

2. Reduction in premium discount.

The standard premium discount offered to residual market risks (that are eligible) is based on the stock discount table. However, a number of states have approved the use of non-stock discounts (which are lower) for residual market risks.

3. Rate or pure premium differentials.

In states with these programs, the rate charged to a residual market risk is higher than the voluntary market rate. The differentials vary by state, but range up to a current high of 29% over the voluntary rate. Some states apply this surcharge only to risks above a certain minimum size. Note that standard NCCI practice is to use the same rating values (i.e., the components used to calculate the experience modification factor) for both the voluntary and assigned risk markets. Thus, a risk will have the same experience modification whether it is insured in the voluntary market or the assigned risk market.

In a situation where the rate level indications are determined on a combined (voluntary and residual market basis) and the rating values are also based on combined experience, then the combined total premium generated should be reasonable (assuming proper ratemaking techniques).

In this situation, if the residual market loss experience is worse than the voluntary market loss experience, the residual market will tend to have above average mods while the voluntary market will have below average mods.

Now consider a situation, where based on the adverse loss experience of the residual market, a rate surcharge is applied to the residual market risks, but the experience mods are calculated in the same fashion as described above.

In this case, there is a risk of double-counting the residual market adverse experience, once in the rate level and once in the experience mod calculation.

Problems with potential double-counting are discussed further later in this subsection.

MISCELLANEOUS

4. Flat dollar surcharge.

As a variation on the rate differential program, in Florida, risks in the assigned risk plan are charged a flat fixed dollar amount surcharge on a per risk basis.

5. Assigned Risk Adjustment Program (ARAP).

This program adjusts the premium upward for assigned risks that are experience rated, based on their actual historical loss experience (i.e., it is a prospective adjustment). This program, like all the other residual market programs, was created to respond to the fact that the residual market loss ratio experience was worse than the voluntary market experience. However, the ARAP, does not target all risks, but only surcharges those risks with adverse historical loss experience.

6. Assigned Risk Rating Program (ARRP).

This program adjusts the premium upward based on actual losses during the experience period. In other words, it acts somewhat like a retrospective rating plan. This program is only applied to larger sized risks, with the actual cutoff varying by state.

C. Ratemaking Adjustments for Residual Market Surcharge Programs

NCCI classifies the premium adjustment programs into two types, standard premium programs and net premium programs. The standard premium programs are all those programs where the premium adjustment affects a risk's standard premium. This would include the programs mentioned in items 3, 4, and 5, above. (That is, the rate differential, the rate surcharge, and the ARAP.) The net premium programs are those where the risk's net premium is modified, but the standard premium remains unchanged. This would include the programs mentioned in items 1, 2, and 6, above. (That is, the adjustments of premium discount, and the ARRP program.)

For the standard premium programs, NCCI practice is to always include the additional revenue in the premium base (since it is reported with the Designated Statistical Reporting Level (DSR) standard premiums and is not readily separable), and to adjust the on level calculations to reflect the current level of the various surcharges. The exact details on how these adjustments are made can be complex. They are discussed in more detail below.

MISCELLANEOUS

For the net premium programs, the additional revenue must be estimated since it is not included in the reported standard premiums. NCCI chooses whether or not to reflect this additional revenue based on their assessment of the situation in the particular state. If the additional revenue is reflected, adjustments are also made to the premium on level factors.

NCCI has indicated that they have four different methods to reflect standard premium programs in their on level factor calculations. Originally, there were only two methods, but these methods are being replaced by two additional methods. The original two methods performed adequately when adjusting premiums to current level for the purpose of determining the overall rate level indication. However, NCCI states that they introduced distortions in trend factors when the relative size of the assigned risk market was changing. Therefore, NCCI introduced the second two methods to adjust for this distortion. All four methods are described below.

In addition, we describe the kinds of adjustments NCCI makes to estimate the effects of the net premium programs.

1. Standard Premium Method 1.

In some states, assigned risk surcharge programs are introduced on a revenue neutral basis. That is, all rates are reduced to reflect the additional revenue from the assigned risk plan. When this happens, and the assigned risk market share is constant, there may be no need to reflect the surcharge program in the on level factor calculation, since there is no additional revenue created by the program on a total market basis. We have not included an example demonstrating this method simply because the on level calculation would be identical to that in a state with no residual market premium programs.

2. Standard Premium Method 2.

In this method, separate on level factor calculations are performed for the voluntary market and for the assigned risk market. The two on level factors are weighted together using the current policy period's respective market shares as weights. Several examples of this method are attached as Exhibit 9. In Alaska, the on level factor is a weighted average of the voluntary and assigned risk on level factors. Use of this factor will put voluntary premiums on the latest voluntary rate level and assigned risk premiums on the latest assigned risk rate level assuming the voluntary and assigned risk market shares are constant. In other words, the on level factor represents the average rate level change for voluntary and assigned risks, combined. For Arizona, the assigned risk on level factor is first divided

MISCELLANEOUS

by the current assigned risk rate deviation factor, before it is weighted with the voluntary on level factor. This, in effect, will put all premiums on the current voluntary rate level.

3. Standard Premium Method 3.

In this method separate indications are calculated for voluntary and assigned risks and the experience is combined. Therefore, there is no explicit consideration of the voluntary and assigned risk market share. An example of this method is attached as Exhibit 10 (Louisiana).

4. Standard Premium Method 4.

In this method, separate on level calculations are performed for the voluntary and assigned risk premiums. The weighting methodology has been revised by use of a "market share adjustment factor". The purpose of this factor is to make adjustments when the assigned risk market share is changing. Thus, historical premiums are brought to the current rate levels and the current market share level. Examples of this method are attached as Exhibit 11. The market share adjustment factor is .999 for Iowa and .997 for Indiana and is applied to the combined voluntary and assigned risk on level factor that is calculated via method 2. Documentation on the derivation of the market share adjustment factor is not included along with the standard rate filing materials. NCCI provided us with a sample calculation of a market share adjustment factor for Florida, which resulted in a factor of 1.000 for Calendar Year 1989 and a factor of .999 for Policy Year 1989 (Exhibit 12).

After rearranging the terms in the formula used by NCCI, the market share adjustment is calculated by dividing two on level factors. The formula for the numerator is :

$$\frac{\text{Voluntary Rate} \times \text{Current AR \%} + \text{Current Voluntary \%}}{\text{AR Rate}}$$

This factor converts premium at current rate level and current market share to the voluntary rate level.

The denominator is:

$$\frac{\text{Voluntary Rate} \times \text{Projected AR \%} + \text{Projected Voluntary \%}}{\text{AR Rate}}$$

MISCELLANEOUS

This factor converts premium at current rate level and projected market share to the voluntary rate level.

If the assigned risk market share is projected to increase, this would result in a market share adjustment of greater than 1.00. This, in turn, would increase the on level premiums and decrease the rate level change, all other things being equal.

D. Estimating Rate Level Effects of Various Surcharge Programs

The rate effect of the various surcharge programs are required for calculating on level factors. This section will highlight the techniques and data sources used by NCCI to accomplish this task.

1. Rate surcharges

If the surcharge applies on a flat percentage basis to all assigned risks, then the rate level calculation is straightforward. Several states have rate surcharges applying to risks above a certain premium size. Exhibit 13 shows the calculation of the rate level effect and the corresponding voluntary offset based on a 25% surcharge on the amount of premium over \$2,000.

Assigned risk policy size information is determined from the PICS (Policy Issue and Capture System). The market share data is determined from the financial calls (for total market data) and Quarterly Assigned Risk Financial Data (for assigned risk data).

2. ARAP

NCCI estimates the projected cost of the ARAP by re-rating historical experience on a risk by risk basis as if the ARAP were in effect. Exhibit 14 shows the supporting data for a Georgia filing.

3. ARR

Based on data from the PICS system, NCCI generates a distribution of premiums by size. Next, NCCI estimates an expected loss ratio for assigned risks starting with the target cost ratio from a rate filing and eliminating loss adjustment expense and any loss based assessments. This is further adjusted for the assigned risk loss ratio differential net of any

MISCELLANEOUS

assigned risk rate programs that modify the standard premium. Then, based on the expected loss ratio and Table M, an average surcharge amount is calculated based on the loss ratio distribution underlying Table M, the expected loss ratio, and the surcharge formulas of the ARR. (Table M is a tool used in the construction of the retrospective rating plan. With Table M, one can estimate the distribution of risks by loss ratio for each premium size group.) Finally, it is assumed that only 85% of the additional ARR premium will be collectable.

A sample of these calculations appears in Exhibit 15.

4. Adjustments to premium discount.

From a distribution of risks by size, NCCI calculates premium before and after the change in discount program. The ratio of these two amounts is the rate level change for assigned risks. Exhibit 16 shows a sample calculation.

E. NCCI Concerns Regarding Net Premium Programs

According to NCCI, they have a number of concerns regarding their methods for estimating the impact of the net premium programs. However, they claim that most of their filings do reflect the impact of these programs in their on level factor calculations.

Difficulties with the ARR program (the surcharge program based on actual current policy period loss experience) cited by NCCI are as follows:

1. NCCI does not use actual loss experience. Instead, they project the distribution of risks by loss ratio by using the Table of Insurance Charges (also known as "Table M").
2. The final ARR premium is based on loss experience as of 18 months past the effective date of the policy. NCCI is concerned that this premium may not be collected, and therefore on level premiums may be overstated. (Current NCCI procedure assumes that 15% of the surcharge premium will not be collectable.) This issue has some important regulatory repercussions. If an individual carrier is unable to collect premium that is due under the residual market rating mechanism, is it equitable to charge all policyholders in the state for this revenue shortfall?

MISCELLANEOUS

3. According to NCCI, if the ARRP succeeds in its aims, it will cause large risks in the assigned risk plan to seek coverage in the voluntary market. If this happens, the net premium impact may be smaller than estimated under the above methodology.

F. Conclusions and Recommendations

In general, we believe that the standard NCCI procedures to reflect additional revenue from residual market policies are reasonable. However, we have a number of concerns regarding some related issues. These are presented below.

1. Potential problem of double-counting adverse experience.

There are two areas where this problem may arise.

- a. The use of a single set of experience modification plan parameters for voluntary and residual market risks in states that have rate differential programs. The experience rating parameters (i.e. expected loss rates) are the same whether a risk is paying the lower voluntary rate level or the higher assigned risk rate level. Under certain situations, this could serve to double-count the adverse experience of risks in the assigned risk plan. On the other hand, a uniform set of rating values makes administration of the experience rating plan easier. There are three elements that could interact to cause double-counting of residual market adverse experience; higher residual market rates, experience rating values, and ARAP.

NCCI could test whether double-counting exists by adding some additional calculations to their estimates of the impact of ARAP. These additional calculations should include an estimation of loss ratios of assigned risk business and voluntary business after the impact of ARAP, higher residual market rates, and experience modification factors. The goal of all three programs is to have risks pay an equitable price. Double-counting would be a problem if the combined effect of more than one rating program reduced the loss ratio for an identifiable group of residual market risks below that of a similar group of voluntary risks.

At the present time, we would characterize the issue of potential double counting as a design consideration for future surcharge programs rather than as something likely to be a problem with current plans. Based on a review of several states, the overall

MISCELLANEOUS

impact of the current assigned risk plans was quite a bit less than the current assigned risk revenue shortfalls.

b. The application of a single offset for assigned risk rate differentials applied to all classes results in a larger than necessary offset for some classes and a smaller than necessary offset for others. Classes that are heavily written in the assigned risk market will not have their manual rates lowered enough to fully offset surcharge income. This may or may not result in assigned risk insureds being overcharged, depending on the magnitude of the surcharge program, and the concentration of the class in the assigned risk market. NCCI should study this situation to see if a practical equitable solution can be devised.

2. Improve explanatory material in the rate filing.

The standard rate filing does not contain sufficient information to review the calculations underlying the derivation of all the assigned risk plan premium adjustment factors. NCCI should improve the supporting materials.

3. Net premium programs contemplating additional revenue for assigned risk policyholders should be reflected in all states as a standard methodology.

We believe the filing should measure the impact of all premium revenue sources in calculating rate level indications as a standard procedure. If there are compelling reasons to modify or exclude the calculated effect of the assigned risk plan net premium programs, NCCI could treat this like any other data anomaly.

4. When data becomes available as to the collectability of ARRPs premium surcharges, NCCI should replace the assumed 85% collectable percentage with a figure based on actual experience.

V. EXPERIENCE RATING PLAN OFF-BALANCE

At the request of the Examination Oversight Group, we have included the response to this objective in our report entitled Section IIB, Part 7 - Experience Rating.

MISCELLANEOUS

[REDACTED]

MISCELLANEOUS

VI. CALENDAR/ACCIDENT YEAR VS. POLICY YEAR LOSS RATIOS

A. Background

This section of the report was requested by the NAIC in June, 1991 as additional research. The objective of the analysis was to test for any consistent tendency of the calendar/accident year loss ratio used in a rate filing to be higher or lower than the corresponding policy year loss ratio, after adjusting for trend.

B. Description of Tests

1. Loss Ratio Tests

Our loss ratio tests compared the following pairs of calendar/accident year and policy year loss ratios:

Policy Year 1986 and Calendar/Accident Year 1987 ("PY86 & AY87")

Policy Year 1987 and Calendar/Accident Year 1988 ("PY87 & AY88")

Policy Year 1988 and Calendar/Accident Year 1989 ("PY88 & AY89")

These are the pairs of ratios which, for most states, were used in developing the rate indications for filings effective in 1989, 1990 and 1991 respectively.

NCCI provided us with the premium and loss data for each of the years. This information was adjusted as follows:

- policy year premiums were developed to ultimate;
- losses were developed to ultimate;
- losses were adjusted to a common benefit level;
- premiums were adjusted to a common rate level.

████████████████████

MISCELLANEOUS

NCCI also provided us with medical and indemnity trend factors. The trend factors provided were derived from the 1989 through 1991 filings, by adjusting each actual factor used in the filings to an average annual basis.

From this data, we calculated the loss ratios as follows:

$$\frac{\text{Adjusted Losses}}{\text{Adjusted Standard Earned Premium}}$$

The calendar/accident year loss ratio was then divided by:

$$(1 + \text{Trend Factor})^{6.7/12}$$

to reflect a common claim cost level as is reflected in the policy year loss ratio. (Based on NCCI's countrywide distribution of premium written by month, the average accident date for the calendar/accident year is approximately 6.7 months after the average accident date for the previous policy year.)

The resulting loss ratios are shown on Exhibit 17.

In our report on premium and loss development factors (Section IIB, Part 1), we concluded that the adjustment of calendar year premium to current rate level does not consider the contributions to calendar year premiums arising from audit adjustments to older policy years. The magnitude of the error varies by state based on rate level changes, growth in exposures, and premium earning patterns. We estimated that, for most states, the theoretically correct value of adjusted calendar year premiums would be less than two percent higher than that resulting from NCCI's current calculations.

Based on this conclusion, a tendency for the calendar/accident year loss ratio to be higher than the policy year loss ratio is not unexpected. The next step of our analysis was to adjust the calendar year premiums for this estimated understatement in the current rate level adjustment. The purpose of our adjustment was not to derive a precise estimate of the current rate level factor for each state and for each calendar/accident year. Rather, the purpose was to calculate an average adjustment factor to apply to the NCCI current rate level factor.

MISCELLANEOUS

Thus, for each state we calculated the average adjustment factor taking into account:

- Average annual increase in premium levels (over the period 1985 - 1989);
- Average annual change in rate levels (over the same period);
- Policy year premium earning pattern.

The adjustment factors were derived using the approach described in Section IIB, Part 1, "Premium and Loss Development Factors". The factors resulting from this approach are summarized on Exhibit 18.

We adjusted each of the calendar year premiums by the factor, and recalculated the loss ratios. The resulting loss ratios are shown on Exhibit 19.

On Exhibit 20, we have calculated the ratio of the calendar/accident year loss ratio to the policy year loss ratio for each state and each pair of years. Exhibit 21 provides a summary of the results for each policy year and calendar/accident year combination. We observe that the PY86 & AY87 (Exhibit 21, Sheet 1) and the PY88 & AY89 (Exhibit 21, Sheet 3) loss ratios are reasonably consistent. On average, the calendar/accident year loss ratio is less than one percent higher than the policy year loss ratio, and approximately half of the states have policy year loss ratios which are greater than the calendar/accident year loss ratio. We conclude that, for these years, there is not a significant difference between the accident year and policy year loss ratios.

For PY87 & AY88 (Exhibit 21, Sheet 2), the results are different. The calendar/accident year loss ratio is consistently (nearly 75% of the states) and materially (2% to 7% on average) higher than the policy year loss ratio. To further explore possible reasons for these differences, we have compared the underlying premiums.

2. Premium Tests

NCCI provided us with premium data for policy years 1987 and 1988, and calendar year 1988. We would expect that, after adjusting the premium data to reflect:

- Policy year development to ultimate;
- Adjustment to common rate levels; and,

MISCELLANEOUS

- Matching companies,

the calendar year premium would usually be between the two policy years' premiums, and would generally be close to the average of the two policy years' premiums.

Exhibit 22 compares the premium values. On the exhibit, we have ranked the three premium values for each state. We would expect the calendar year premium to have a ranking of 2, indicating that it is between the two policy year values. Exhibit 22 shows that this occurs in fewer than half of the states (fourteen of thirty-five). Further, we note that for eighteen of the remaining twenty-one states, the calendar year premium was the lowest of the three. This suggests that the calendar year premiums are understated or the policy year premiums are overstated.

This can also be seen in the thirty-five state totals. The calendar year premium (\$17.1 billion) is less than the surrounding policy year premiums (\$17.5 billion and \$17.9 billion).

As with the loss ratios, we have recalculated the calendar year premiums to reflect the current rate level adjustment described above. The results of this calculation are shown on Exhibit 22, Sheet 2. While the adjustment does bring a few states closer to our expectation, the results still suggest an inconsistency in the two premium bases.

We requested that NCCI investigate the causes for these inconsistencies and determine whether they are evident in the other years. Exhibits 23 and 24 present the comparisons for two other calendar year/policy year combinations. Exhibit 23 shows the premiums for policy years 1986 and 1987 and calendar year 1987. (Sheet 1 shows the unadjusted calendar year premiums; Sheet 2 shows the calendar year premiums after reflecting the current rate level adjustment.) Exhibit 24 shows the premium rankings for policy years 1988 and 1989 and calendar year 1989. (NCCI indicated that individual states' premium data cannot be shown since the information was not yet used in state rate filings. The premiums used in Exhibit 24 do not reflect the current rate level adjustment.) While there are some states for which the premiums exhibit inconsistencies (for example, Michigan and Oklahoma for calendar year 1987), the totals are in line with our expectations. For these years, calendar year premiums are between the policy year premiums for approximately two-thirds of the states, and the countrywide totals are reasonable.

These exhibits suggest that, while there appear to be some inconsistencies in the policy year and calendar year premiums in all three years, the differences are most pronounced in calendar year 1988.

[REDACTED]

MISCELLANEOUS

This observation is consistent with the results of NCCI's investigation. In reporting on their investigation, NCCI stated:

"There appear to have been some data problems in the past causing possible distortions in the calendar year premiums. We found that the policy year 1/2 / 1st development factors (12 months to 24 months) seem to be inconsistent from year to year for a few carriers. This suggests that companies may have changed the way in which they code their policy year premium for the half report (12 months). This can cause a one time shift in the calendar year premium."

NCCI further stated:

"When we investigated individual carrier data as mentioned above, we noticed that the identified problems were more concentrated in calendar year 1988."

Finally, NCCI indicated that:

"...given the time constraints, we were unable to account for all of the differences."

The premium comparisons above, and the results of NCCI's investigations, lead us to conclude that the differences between the policy year and calendar/accident year loss ratios observed above are likely to be due largely to inaccuracies or inconsistencies in the premium data underlying the loss ratios.

We recommend that NCCI continue to investigate the reasons for the premium differences in those states where they are most pronounced. We also recommend that NCCI strengthen the process for editing carriers' calendar and policy year premium reports for consistency.

C. Conclusions and Recommendations

Our tests focused on:

Policy Year 1986 and Calendar/Accident Year 1987 ("PY86 & AY87")
Policy Year 1987 and Calendar/Accident Year 1988 ("PY87 & AY88")
Policy Year 1988 and Calendar/Accident Year 1989 ("PY88 & AY89")

████████████████████

MISCELLANEOUS

For each state, and for each pair of years, we calculated the following ratio:

$$\frac{\text{Calendar/Accident Year Loss Ratio}}{\text{Policy Year Loss Ratio}}$$

after making appropriate adjustments to put the loss ratios on a common level with regard to rates, benefits and trend.

For PY86 & AY87 and PY88 & AY89, the average ratios are less than 1.01. That is, the calendar/accident year loss ratio is less than one percent higher than the policy year loss ratio. For these two pairs of years, approximately half of the states have policy year loss ratios which are less than the calendar/accident year loss ratios and for half of the states the relationship is reversed.

However, for PY87 & AY88, nearly 75 percent of the states have calendar/accident year loss ratios exceeding the policy year loss ratio, and the average ratio is 1.049. These results suggest that the calendar/accident year 1988 loss ratio is overstated and/or the policy year 1987 loss ratio is understated.

The comparative exhibits presented in this report, coupled with NCCI's investigation into some observed premium differences, suggest that the PY87 & AY88 loss ratio inconsistencies are attributable largely, or entirely, to premium data problems. Further, NCCI's investigation suggests that the problem is concentrated mostly heavily in calendar year 1988.

In general, the policy year and calendar/accident year loss ratios used in recent rate filings appear to be reasonably consistent with each other. Calendar/Accident Year 1988 appears to be an exception. The difference appears to be caused by inconsistencies between policy years 1987 and 1988 and calendar year 1988 premiums. NCCI could not identify all of the causes of the apparent premium anomaly. This does not appear to be a problem with respect to 1991 filings which are based on calendar year 1989 and policy year 1988. However, we recommend that NCCI continue to investigate the reasons for the premium differences in those states where they are most pronounced. We also recommend that NCCI strengthen the process for editing carriers' calendar and policy year premium reports for consistency.

Note: Data based on 1982 Special Call for distribution of Expenses by Size of Risk for Stock Companies

Predicted Expenses based on the following formula:

(Avg Policy Size - Avg Expense Constant in 1982) x (General Expense Indication used in 1982) + (Portion of Proposed Expense Constant for General Expense)

where: Avg Expense Constant in 1982 = 36.00

General Expense Provision = 7.5%, 4.9%, 4.7%, and 3.1%
Expense Constant Portion for General Expense = 62.63

Predicted Expenses based on Individually calculated expenses weighted by number of policies

Average of all Policies: 0.024

EXPLANATORY NOTES

The following items should be noted in this exhibit:

- 1) ARAP represents the Assigned Risk Adjustment Program, a pricing mechanism for experience rated assigned risks to share in the underwriting losses generated by the residual market.
- 2) ARRP represents the Assigned Risk Rating Program, a loss sensitive rating program for assigned risks developing annual standard premium in excess of a specified amount. This amount is specified in this exhibit for the affected states.
- 3) APA represents the Accident Prevention Account in Maine.
- 4) Mod represents the experience modification, a value sometimes used in determining subjectivity to residual market programs.
- 5) Differential implies assigned risk rates which are a specified percentage over voluntary or advisory rates.
- 6) Pure Premium Differential implies assigned risk pure premiums which are a specified percentage over voluntary or statewide pure premiums.
- 7) Reduction of Premium Discounts represents the application of non-stock premium discounts in lieu of stock premium discounts for assigned risk insureds.
- 8) Programs with two dates are those no longer in effect, where the second date represents the elimination date.

**ASSIGNED RISK
ADJUSTMENT PROGRAM
(ARAP)**

ASSIGNED RISK ADJUSTMENT PROGRAM

Purpose

The purpose of this filing is to provide a revised pricing mechanism for experience rated assigned risks to share in the underwriting losses generated by the assigned risk market. This proposal will surcharge risks with a record of losses greater than expected under the experience rating plan.

Background

The residual market is intended to serve as the market of last resort to ensure the availability of workers compensation and employers liability insurance to all employers required by law to provide this coverage but unable to obtain it through the voluntary market.

Between 1984 and 1988, the residual market suffered an operating loss exceeding 4.4 billion dollars. Carriers writing voluntary insurance continue to absorb the increased burden being placed on them by the rapid expansion of the residual market. In NCCI jurisdictions, the subsidy for both 1987 and 1988, amounted to just over 12%. This means that for every dollar of voluntary market premium, 12¢ must be used to subsidize the increased loss experience in the residual market. These subsidies are causing severe financial hardships to insurance carriers. As a result, competition among voluntary carriers has diminished.

The residual market has evolved into more than a market of last resort. Nineteen-eighty-eight (1988) data shows that the number of risks and the amount of premium have grown significantly in the past five years. In 1984, assigned risk plans administered by NCCI provided coverage for 253,000 risks. During 1988, there were approximately 580,000 risks covered by plans administered by NCCI. The written premium for these risks accounts for approximately 2.9 billion dollars, representing 19.3% of the total written premium in those jurisdictions.

The residual market has become the largest segment of the total workers compensation insurance market. Its premium volume now more than doubles that of the largest single private writer of workers compensation and employers liability insurance.

Proposal

It is proposed that the attached Assigned Risk Adjustment Program (ARAP) be implemented six months from the approval of this program or from the latest rate filing effective date whichever is later.

Impact

The proposed surcharge will range from 0 to a maximum of +49% of standard premium. The average surcharge will vary between 10% to 15% of standard premium, depending largely on the distribution of risks by size in the assigned risk pool and the extent of the rate level deficiency of assigned risk pool business in a given state.

Implementation

In order to implement this proposal, the attached exhibit illustrates the changes required in the Experience Rating Plan Manual.

ASSIGNED RISK ADJUSTMENT PROGRAM (ARAP)

Administration Rules and Procedures

1. **Eligibility** - A risk shall be eligible for the Assigned Risk Adjustment Program if it is eligible for an experience rating modification. The application of this program is mandatory for all eligible insureds and shall apply to all assigned risk policies written for such insureds.

2. **ARAP Surcharge Formula** -
 - (a) After the calculation of the experience modification factor "M" for a particular risk, the weighted test ratio "R" is calculated

$$R = \frac{(0.5 - 0.5W) A_p}{M \cdot E_p} + \frac{(0.5 + 0.5W) A}{M \cdot E}$$

where:

- W is the weighting value
- A is the actual losses, as limited on a per accident basis
- A_p is the actual primary losses
- E is the total expected losses
- E_p is the expected primary losses
- M is the experience modification

All values are those used in the experience modification calculation.

- (b) If "R" is greater than 1.0, a surcharge factor "S" will be calculated using the following formula:

$$S = 1 + \frac{(0.08) E (R-1)^{1.25}}{(E + 3)^{0.5}}$$

where:

- E is the total expected losses of the particular insured shown in thousands. "E" shall not exceed 40.
R is the weighted test ratio calculated in 2(a). "R" shall not exceed 2.0.

- (c) The surcharge factor "S" will appear on all rating forms. This surcharge factor will be applied to the standard premium developed in the state(s) where effective.

3. The surcharge is limited to a maximum of 49% of standard premium. Only insureds with expected losses equal to or greater than \$40,000 will be subject to the maximum surcharge. The following table shows sample maximum surcharges by risk expected loss size.

<u>Risk Expected Losses</u>	<u>Maximum Surcharge</u>
2,500	9%
5,000	14%
10,000	22%
25,000	38%
40,000 and over	49%

4. Definitions

For the purposes of this program, the following definitions apply:

- (a) Weighted Test Ratio - A comparison of the risk's actual losses to the modified expected losses. A ratio greater than 1.00 is subject to the ARAP surcharge. This test ratio is limited to 2.00.
- (b) ARAP Surcharge Factor - The factor is applied to the normal standard premium when the insured is an assigned risk. This factor is determined by a formula using the weighted test ratio.

5. Experience rated risks with multi-state operations shall be subject to the Assigned Risk Adjustment Program in states that have approved it. For risks with interstate exposure, the "R" (test ratio) and the "S" (surcharge) values will be computed on a full interstate basis. In ARAP states, "S" will be used to develop the surcharged premium in those states only.

GEORGIA

CALCULATION OF ARAP SURCHARGE FACTOR

The impact of ARAP on Georgia Assigned Risk premium is 13.3%.

NCCI uses experience rating data files to calculate an ARAP surcharge factor for every assigned risk policyholder (risk) which was experience rated during 1986, and had a risk identification number available in NCCI's PICS database. The formula used and a sample calculation can be found in Exhibit 1, Page 3. After all individual calculations are completed, we obtain a weighted average using the latest available year's expected loss as weights. This average is our estimate of the effect of introducing the ARAP program.

It can reasonably be assumed that results in the prospective rating year will not differ substantially from what would have been developed in the historical rating year (as if the plan were in effect at that time).

Exhibit 1, Page 2 summarizes the results by size of modification and size of expected loss. The top part of the exhibit show how the ARAP surcharge impacts insureds grouped by size of experience rated modification (Mod) in ascending Mod order. The bottom part illustrates this same comparison by expected loss range. On both parts, the last column is the distribution of the latest historical year's expected loss for each category. NCCI has also estimated the proportion of risks not experience rated using the standard premium found in the PICS database.

An interpretation of the ARAP formula can be found in Exhibit 1, Page 4.

FORMULAS USED TO CALCULATE THE ARAP SURCHARGE
AND INTERPRETATION

The surcharge(s) is calculated for each risk using the following formula:

$$S = 1 + \frac{(.08) \cdot \bar{E} \cdot (R-1)^{1.25}}{(\bar{E} + 3)^{.25}}$$

where $R = \frac{(.5 - .5W)A_p}{E_p \cdot M} + \frac{(.5 + .5W)A}{E \cdot M}$ and capped between 1 and 2

M = Experience Rating Modification (Mod)

and from the rating sheet as contained in NCCI Experience Rating files:

A_p = Actual Primary Losses

E_p = Expected Primary Losses

A = Actual Total Losses

E = Expected Total Losses

W = Weight from Mod Calculation

\bar{E} = Expected Total Losses In Thousand Dollar Units Limited to 40

Sample Calculation:

Assume: $M = .99$ $A = 50,000$
 $A_p = 9,000$ $E = 30,000$
 $E_p = 12,000$ $W = .11$ (Revised Experience Rating Plan)

$$R = \frac{(.5 - .5(.11)) 9,000}{12,000 (.99)} + \frac{(.5 + .5(.11)) 50,000}{30,000 (.99)}$$

$$= \frac{4,005}{11,880} + \frac{27,750}{29,700} = 1.27$$

$$S = 1 + \frac{(.08) 30 (.27)^{1.25}}{(30 + 3)^{.25}} = 1 + \frac{.4671}{3.7445} = 1.12$$

Explanation of ARAP Formulas

The experience rating formula is designed to use a risk's past loss experience (actual losses (A) versus expected losses (E)) to predict the risk's future experience. The formula relies more on the risk's primary losses (A_p) rather than their excess losses, i.e. the prediction is based more on loss frequency than on loss severity. In depending more on frequency, the effect of a "one-time" catastrophe is significantly diminished.

To make the residual market more self-supporting, the ARAP formula relies more on total losses (A) when calculating a surcharge factor. However, for smaller risks, the ARAP formula only goes halfway towards recognizing the full total losses by giving half weight (W) to primary losses (A_p). This once again minimizes the impact of a single catastrophe loss.

As risk size increases, the ARAP formula goes more than halfway toward relying on total losses (A) to calculate the risk's surcharge.

The "R" formula is the first step in determining the ARAP surcharge. If the result of the "R" formula is greater than 1.0 a surcharge is calculated by substituting the result of the "R" formula (limited to a maximum of 2.0) into the "S" equation. The ARAP surcharge determined in the "S" equation depends not only on actual versus expected losses, but also on the magnitude of expected losses (expected losses in the "S" formula are limited to \$40,000).

The surcharge as calculated in the "S" equation will limit automatically at the maximum surcharge for each expected loss size. The smallest risks just eligible for experience rating will have a maximum surcharge of +9%, where risks over \$40,000 in expected losses can be surcharged up to +49%.

ASSIGNED RISK RATING PROGRAM

1. State: Georgia
2. Effective Date: 11/20/90
3. Assigned Risk Rating Plan Eligibility Level: \$50,000
4. Average Surcharge Amount: +8.1%
5. Expense Constant: \$140
6. Loss Conversion Factor: 1.120
7. Tax Multiplier: 1.102 State
1.223 "F" Class Only
8. Expense and Development Ratio: 0.469

NOTE: These factors are based on the expenses and loss development factors proposed in the latest rate filing.

IMPORTANT NOTICE TO

Workers Compensation Assigned Risk Policyholders

Your Policy Is Written through the Assigned Risk Plan

All workers compensation assigned risk policyholders with audited standard premium equal to or greater than the Assigned Risk Rating Program eligibility level are subject to the Assigned Risk Rating Program. This is effective for new and renewal policies in the following states:

The Assigned Risk Rating Program (ARRP) will adjust your premium, based on your actual loss experience, valued eighteen months after the effective date of the policy. You will then be required to submit any additional premium. Depending on your premium size and amount of losses, this additional premium could range from 0% to 100% of your audited premium. Please see the Assigned Risk Rating Program Endorsement for details. This form is attached to your policy.

Applicable effective date of policy: _____

Please read carefully, sign below and return a copy to:

[Servicing Carrier Name]
[Servicing Carrier Address]

This notice must be returned with ten (10) working days to maintain the requested effective date.

Signature of Officer, Sole Proprietor or
Partner.

I understand the above Notice and am unable to obtain coverage in the voluntary market.

DUPLICATE

Note: The size and style of type can be changed at the carrier's discretion.

GEORGIA
ASSIGNED RISK PROGRAM

Assigned Risk Rating Program (ARRP)

Summary

(1) Calculated average Surcharge due to operation of loss-sensitive formula (See Exhibit 2B)	0.095
(2) Amount assumed uncollectible	0.150
(3) Adjusted average Surcharge = (1) x [1.000 - (2)]	0.081

GEORGIA

GEORGIA
ASSIGNED RISK PROGRAM

Calculation of Overall Expected Pure Loss Ratio for Assigned Risks

(1) Expected Overall Loss Ratio (Vol. & A/R From Exhibit 2E)	0.594
(2) Expected Loss Ratio differential of Assigned Risks to all risks assuming overall rate adequacy and implementation of ARAP. See Exhibit 3A	1.229
(3) Expected Overall Loss Ratio for Assigned Risks (1) x (2)	0.730

GEORGIA
ASSIGNED RISK PROGRAM

Calculation of Average Surcharges by Premium Range for ARR

Definition of Terms and Formulas #

-
- R - Retrospective premium
 - TM - Tax multiplier = $1 / [1 - \text{tax provision (including assessment)}]$
 - b - Basic premium
 - c - Loss conversion factor (in this case, LAE)
 - L - Actual losses
 - E - Expected losses
 - r - L / E - Ratio of actual to expected losses
 - Table M (or "Table of Insurance Charges") entry ratio
 - R - $(b + cL) \times TM = (b + crE) \times TM$
 - G - Maximum premium
 - $(b + cR_G E) \times TM$, where R_G is the maximum entry ratio

$$\longrightarrow R_G = \frac{G / TM - b}{cE}$$

- H - Minimum premium
- $(b + cR_H E) \times TM$, where R_H is the minimum entry ratio

$$\longrightarrow R_H = \frac{H / TM - b}{cE}$$

- X_G - Table M charge at entry ratio R_G
- requires the knowledge of R_G and the Expected Loss Group , which depends on
- expected average loss dollars.

- X_H - Table M charge at entry ratio R_H
- S_H - Savings at entry ratio R_H , where $S_H = X_H + R_H - 1$

Thus,

$$\text{Average Surcharge} = \left[\left(b + (L \times LAE) \right) \times TM \right] - 1$$

Where $L = \text{ARRP formula loss ratio} = \text{Expected loss ratio} \times (1 - X_G + S_H)$

since losses over the maximum (X_G) will not enter surcharge formula, while the insured receives no credit for having losses below the level which generate the minimum surcharge (S_H).

Note that this last formula differs from those found in Snader because ARRP is not a "balanced" plan.

Note: For the average surcharge estimate formula, loss development is included in the losses for presentational purposes and is not included in the expense (b) development ratio. Since the ultimate sum is assumed to be the same, this has no effect on the estimated average surcharge.

The definitions and formulas (except for L) can be found or derived from Snader, Richard H., "Fundamentals of Individual Risk Rating", published by the Casualty Actuarial Society.

GEORGIA
ASSIGNED RISK PROGRAM

CALCULATION OF THE AVERAGE SURCHARGE BY RANGE

(1) Premium Range	(2) R _G	(3) R _H	(4) Expected Loss Group *	(5) X _G	(6) X _H	(7) S _H	(8) Average Surcharge
0 - 24,999			84				0.000
25,000 - 49,999			62				0.000
50,000 - 99,999	1.29	0.81	53	0.463	0.584	0.394	0.107
100,000 - 249,999	1.52	0.81	42	0.301	0.484	0.294	0.163
250,000 - 499,999	1.75	0.81	34	0.181	0.413	0.223	0.207
500,000 - 999,999	1.92	0.81	30	0.129	0.376	0.186	0.221
Over 1,000,000	1.92	0.81	23	0.061	0.315	0.125	0.227

* Uses ELG's of R-1257.

Example for the 100,000 - 249,000 Range :

$$G = 1.64$$

$$H = 1.00$$

$$R_G = 1.52$$

$$R_H = 0.81$$

Expected Losses - \$ 109,380

$$\longrightarrow \text{E. L. G.} = 42$$

Given $R_G = 1.52$ and E. L. G. = 42

$$\longrightarrow X_G = 0.301$$

Given $R_H = 0.81$ and E. L. G. = 42

$$\longrightarrow X_H = 0.484$$

$$S_H = X_H + R_H - 1 = 0.294$$

$$* \quad L = (\text{ELR}) \times (1 - X_G + S_H) = 0.730 \times (1.000 - 0.301 + 0.294) = 0.725$$

$$\begin{aligned} \text{Average Surcharge} &= ([\text{Basic Premium Factor} + (L \times \text{LAE})] \times \text{TM}) - 1.000 \\ &= ([0.241 + (0.725 \times 1.120)] \times 1.104) - 1.000 = 0.163 \end{aligned}$$

GEORGIA
ASSIGNED RISK PROGRAM

Calculation of Basic Premium Factor

(1a) Loss Adjustment Expense (From NCCI Rate Filing)	1.120
(1b) Subsequent Inj. Trust Fund (Related to Losses) (From NCCI Rate Filing)	1.029
(2) Target Cost Ratio (Voluntary & Assigned Risk) (From NCCI Rate Filing)	0.6843
(3) Expected Loss Ratio ((2) / [(1a) x (1b)])	0.594
(4) Tax Multiplier (From NCCI Rate Filing)	1.104
(5) Expenses ([1.000/(4)] - (3))	0.312
(6) Basic Premium Factor ((5) - ([(1a)-1.000]x(3)))	0.241

GEORGIA
ASSIGNED RISK PROGRAM

Summary of Loss Ratio Differentials

(1) Loss ratio differential in the absence of any surcharge programs (See Exhibit 3B)	1.462
(2) Estimated impact of ARAP (See Exhibit 1)	1.133
(3) Loss ratio differential assuming ARAP (Std. premium basis) = (1) / (2)	1.290
(4) Assumed Assigned Risk market share	0.168
(5) Differential of A/R ELR to (Voluntary plus A/R ELR) (Std. premium basis) :	

$$V \times (0.832) + P \times (0.168) = 1.000$$

$$V \times (0.832) + V \times (1.290) (0.168) = 1.000$$

$$0.832 V + 0.217 V = 1.000$$

$$1.049 V = 1.000$$

$$\implies V = 0.953$$

$$\implies P = 1.229$$

TOTAL	\$3,565,073,728	\$1,944,677,313	0.545		

* Developed to a fifth report and brought to 7/1/89 premium level.

** Developed to an ultimate report using paid losses to a fourth report, ex-bulk losses from a fourth to eighth report and including IBNR losses from an eighth to ultimate report.

*** Adjusted for effect on assigned risk net premium of 1.081 due to (1) removal of assigned risk premium discounts.

Note also that the Voluntary and the Assigned Risk do not sum to the statewide. This is because the methodology used in the calculation of the statewide on-level factors and rounding problems involved in separate Voluntary and Assigned Risk loss development factors, where the Assigned Risk factors are for indemnity and medical combined.

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM

1. The NCCI files loss costs with provisions for:
 - a. Prospective losses by classification which reflect loss development, trend, and anticipated benefit levels
 - b. Assigned risk subsidies to be paid by the voluntary market
 - c. Loss-based assessments
 - d. Loss adjustment expense
 - e. Disease loss components
2. The NCCI distributes information relating to its loss cost calculations including (1) alternative approaches for loss development and trend, (2) information on benefit change calculations, (3) information on judgmental decisions such as classification relativity capping, (4) the difference between voluntary and residual market experience overall (and by classification, if relevant), etc.
3. The NCCI also distributes historical and factual information with regard to:
 - a. Premium taxes
 - b. Assessments
 - c. Historical information on other insurer operating expenses with appropriate categorization and adjustment for policyholder size and assigned risk service expense considerations
 - d. Premium comparisons
 - e. Individual insurer loss experience compilations
 - f. Expense studies by size of policyholder

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM (CONT.)

4. The NCCI administers an Experience Rating Plan, which is common to all policyholders within a state.
5. The anniversary rating date rule continues.
6. Existing state limitations on individual insurer independence with respect to classification definitions and relativities are continued.
7. The NCCI committees of insurers become advisory.
8. The Classification and Rating Committees continue to assist in adjudicating questions of class definitions and other roles permitted by the state regulator.
9. The NCCI continues to establish residual market plan manual rates.
10. For the voluntary market, the NCCI no longer files:
 - a. Provisions for expenses related to premium tax, production, and general overhead
 - b. Provisions for profit and contingencies
 - c. Expense constants
 - d. Premium discounts
 - e. Minimum premiums
11. The NCCI adjusts rating plans, where necessary, to exclude expenses as noted above. The relevant plans pertain to experience rating, retrospective rating, schedule rating, excess loss rating for employers liability, and other miscellaneous rating items.

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM (CONT.)

12. State regulators, using the NCCI as their statistical agent, develop rules and procedures to maintain and improve the level of data accuracy and availability. This might include increases in field inspections and verification of insurer reported data.
13. Filing procedures for individual insurers are streamlined in a manner analogous to the ISO process, including standardized filing forms appropriate for workers compensation insurance and loading factors that remain in effect until changed by the insurer or disapproved by the regulator.
14. Schedule rating is permitted or not permitted based on current state law and regulation. Where schedule rating is permitted, NCCI filings could include schedule rating, but individual insurers could file independent schedule rating plans.
15. State rating laws remain basically unchanged. Prior approval laws continue to be administered as prior approval for NCCI loss cost filings and for individual company loading factors or other deviations from NCCI advisory material.
16. NCCI continues its other field operations work and its role in maintaining policy forms.

SUMMARY

BACKGROUND

The National Association of Insurance Commissioners (NAIC) has adopted a system for implementing loss costs in property/casualty lines of insurance other than workers compensation. Under the loss cost system, advisory organizations are responsible for the following activities:

- Collecting historical loss information from insurers.
- Developing past losses to ultimate and trending to future cost levels.
- Distributing and/or filing prospective loss cost information.
- Developing and filing rating manuals and supplementary rating information (excluding the final rate pages).
- Developing and filing policy forms and endorsements.

In a loss cost system, insurers must individually determine and file final rates referencing, where appropriate, material filed by the advisory organization. Each insurer's rates are intended to reflect its own method and expense of operation and to the extent credible, its own loss experience.

This approach seeks to promote competition and maximize benefits to consumers. Efficiencies gained through the joint collection and analysis of loss information are preserved, while independence is enforced in the areas of expenses and profits.

The NAIC is investigating the implementation of a similar loss cost system for workers compensation insurance. However, prior to taking action, the NAIC has requested this evaluation of the practical considerations of implementing a nationwide workers compensation loss cost system.

Some of the specific areas identified in the evaluation specifications are the following: (1) minimum premiums, (2) rating plans, (3) premium discount plans, (4) schedule rating plans, (5) expense constants, (6) experience rating systems, (7) policyholder dividend plans and practices, (8) retrospective rating plans, (9) anniversary rating date rules, (10) other rate-related rules, (11) distribution of

SUMMARY

expense data to insurers, (12) changes to the Insurance Expense Exhibit, (13) rate changes to in-force policies, and (14) rate filings with retroactive effective dates.

This report presents the results of the evaluation.

APPROACH

Our approach to achieving the objectives of this project was as follows:

1. Identify the important practical issues using input from the following sources: National Council on Compensation Insurance (NCCI), Insurance Services Office (ISO), insurers, regulators, agents/sales representatives, and policyholders, among others.
2. Examine how those issues are addressed by the procedures actually implemented in workers compensation loss cost states and by ISO for other property/casualty lines of insurance.
3. Describe the structure of a model loss cost system for the NAIC and the practical implications of variations from that model.

In our analysis we focused on the operations of the NCCI and the commercial insurance system in states with an administered-pricing system.

While some states have independent rating organizations which perform some or all of the same functions as NCCI, this report is prepared as part of an examination of the NCCI, and thus the focus of the report is on the NCCI. The conclusions are generally applicable to independent bureau states, but a complete analysis of state-to-state variations is beyond the scope of this report.

Most states have an administered-pricing system which require the NCCI or independent rating organization to obtain prior approval of filings proposing gross rates including insurer operating expenses and profit. The focus of this study is the identification of practical implications of the implementation of a loss cost system for those administered pricing states.

SUMMARY

States without an administered pricing system require the rating organization to file loss costs (in addition to or instead of gross rates). These filings are subject to either prior approval or open competition rating laws. We utilized the loss cost experiences of this second group of states in our analysis.

SUMMARY AND RECOMMENDATIONS

Chart 1 attached to the cover letter outlines the elements of a workers compensation loss cost system "typical" of existing workers compensation loss cost systems, supplemented by concepts from the ISO where appropriate. This typical system provides a reasonable basis for a model workers compensation loss cost system.

As more states adopt loss cost systems that permit greater individual insurer independence, assuring the accuracy of workers compensation data becomes more difficult. The NCCI and independent state advisory organizations should therefore be charged with taking the steps necessary to assure data accuracy.

ADMINISTERED-PRICING SYSTEMS

In NCCI administered pricing states individual insurers generally adhere to rules and rating plans filed on their behalf by the NCCI. Most importantly:

1. NCCI classification definitions and rate relativities are followed by individual insurers.
2. The NCCI collects data on individual policyholder experience and calculates an experience rating modification for each eligible policyholder. The experience modification applies to that policyholder regardless of which insurer provides coverage.
3. The Anniversary Rating Date Rule limits the frequency with which a policyholder can change rates by changing insurers. The rule provides that if a policyholder moves from one insurer to a second insurer during the policy term, then the second insurer must use rates in effect for the second insurer at the original rating date of the

SUMMARY

policyholder. The second insurer must also use the experience modification calculated by the NCCI at the original rating date of the policyholder. When the original rating period expires, a new experience modification is calculated and the current insurer's rates at that time become applicable to the policyholder.

The decisions of the NCCI with respect to ratemaking procedures in the state and with respect to rate filing actions are made by committees of insurers. A committee of insurers also adjudicates disputes between policyholders and insurers with respect to the appropriate classification definitions.

Individual insurers are permitted to vary from NCCI rates in one or more of the following ways:

1. Uniform deviations from NCCI rates for all classifications¹
2. Schedule rating which adjusts individual policyholder rates²
3. Policyholder dividends³

After a rate filing is approved, revised rates are immediately applicable to each insurer without further action by the insurer. Any filed deviations are applied automatically to the newly approved NCCI rates.

In addition to the individual policyholder information used for the experience rating process, the NCCI collects premium, payroll and claim experience from insurers through a number of different data calls. The insurers are required to convert their collected premiums to the premium level of the NCCI before deviations or schedule rating. This adjusted premium is referred to as Designated Statistical Reporting (DSR) level premium.

¹Applicable in nearly all states.

²Applicable in approximately a dozen states.

³Applicable in all states. Outside the jurisdiction of rating organizations.

SUMMARY

The operation of the system in NCCI administered-pricing states is described more fully in Chapter 2.

OBJECTIVES OF A LOSS COST SYSTEM

The advantages of a loss cost system include the following:

1. Independent insurer decision-making is encouraged. A loss cost system should facilitate and encourage initiatives in pricing and operations that will improve the workers compensation system.
2. The appearance of cartel-like behavior among insurers will be reduced or eliminated as collective activities are limited.

If not properly structured, the potential disadvantages of a loss cost system include the following:

1. Increased risk of inadequate, excessive, or unfairly discriminatory rates.
2. Deterioration in data quality.
3. Reduced incentives for workplace safety.
4. Increased cost to operate the workers compensation system.
5. Increased confusion to policyholders, insurers, agents/sales representatives, and regulators.

These potential disadvantages can be minimized by properly structuring the loss cost system.

In comparing the objectives of a loss cost system for workers compensation with the objectives for a loss cost system for other lines of insurance, the following fundamental differences should be considered:

1. For other lines of insurance, the residual market is not managed by the voluntary market advisory organization. For purposes of this study we were

SUMMARY

instructed by the NAIC to assume that the NCCI continues to be responsible for the management of residual market rates. Therefore, unlike the situation for ISO, the NCCI necessarily remains involved in developing gross rates for some markets.

2. The NCCI administers a common Experience Rating Plan applied to all policyholders in the state, no matter which insurer provides coverage. This gives policyholders a common basis on which to measure their workers compensation experience. There is no comparable system in other lines of insurance. Maintaining the experience rating system in that form may imply some limits on the independence permitted to individual insurers.

A TYPICAL LOSS COST SYSTEM

Our examination of existing workers compensation loss cost systems and ISO loss cost systems for other lines of insurance did not reveal any insurmountable obstacles to the implementation of a loss cost system for workers compensation. Ease of implementation and potential long-term effects depend on the structure of the loss cost system adopted.

Chart 1 outlines the characteristics common to existing workers compensation loss cost systems. The Chart also describes historical and factual expense information that the NCCI might collect and distribute. The system outlined in Chart 1 could be implemented with minimal disruption to the workers compensation system consistent with the loss cost concept.

The loss cost system characteristics which differ among loss costs states are the following:

1. Loss adjustment expenses are either (1) included in the advisory organization loss costs or (2) excluded from loss costs and included in individual insurer loadings.
2. Individual insurers are either (1) required to use the advisory organization classification definitions and rate relativities or (2) permitted to establish their own definitions or rate relativities.

SUMMARY

3. Individual insurer loading factors either (1) remain in effect when NCCI loss costs change or (2) must be re-filed when NCCI loss costs change.
4. Uniform filing forms have not been developed to simplify the administration of the regulatory compliance process.

There are many alternatives to this typical loss cost system.

EVALUATION OF THE TYPICAL LOSS COST SYSTEM

Benefits

While the typical loss cost system outlined in Chart 1 may be considered by some to be a minimum step towards a loss cost system, this typical loss cost system includes the two primary features of a loss cost system. It requires that insurers establish their own margins for operating expenses, profit, and contingencies, and decision-making in establishing loss costs is vested in the rating organization rather than insurer personnel. These are also two of the key changes in the ISO loss cost system.

Although the impact of any system change is uncertain, the typical system is likely to have a more significant effect on workers compensation than the system being implemented by ISO will have on other property and casualty lines. For example, the role of dividend competition for workers compensation is likely to be significantly reduced in a loss cost system as it is replaced by competition through loading factors. The transformation from dividend competition to initial price competition is evident in the experience of loss cost states. In the ISO lines, on the other hand, initial price competition, not dividend competition, was the norm before the conversion to loss costs.

Risks--Data Accuracy

The loss cost system in Chart 1 is not obtainable without risk in the area of the accuracy of the data used for overall loss cost analysis by the NCCI. The NCCI depends on individual insurers to report premium converted to the designated

SUMMARY

statistical reporting (DSR) level. For many years insurers have been reporting DSR premium when the only necessary conversions relate to uniform deviations or schedule rating, apparently without significant problems.

However, the loss cost system described in Chart 1 might permit more individual insurer deviations from NCCI loss cost relativities by classification. For this type of deviation, determining the DSR premium is more difficult for the insurer, and verifying the accuracy of the DSR calculation is more difficult for the NCCI. There has not been sufficient experience with this type of system to be confident that accuracy will be achieved without special monitoring efforts by the NCCI. Additional NCCI audit efforts should be required as loss cost systems permitting classification flexibility are introduced.

In the long run, the NCCI may be able to revise statistical plans and reporting procedures to become less reliant on individual insurer DSR calculations.

Perceptions

The system described on Chart 1 permits the NCCI to collect historical expense information, adjust the data to a common basis, and report the data to insurers and regulators. This continued involvement in the expense area may, for some, leave the impression that the system has not sufficiently accomplished the objectives of a loss cost system.

ALTERNATIVES TO THE TYPICAL LOSS COST SYSTEM

Areas of increased insurer independence and reduced rating organization involvement might include the following:

SUMMARY

1. Components of Loss Costs
 - a. Include provision for loss adjustment expenses in individual insurer loadings. This item would be excluded from NCCI loss costs.
 - b. Include provision for residual market subsidies and/or loss-based assessments in individual insurer loadings. These items would be excluded from NCCI loss costs.
2. Experience Rating Plan
 - a. Allow individual insurers to file for the use of their own experience rating adjustments on top of the experience modifications determined by the common NCCI-administered Experience Rating Plan. This approach provides some insurer independence, but maintains a common experience rating plan and the common data base.
 - b. Maintain the NCCI as a statistical agent collecting individual policyholder data and providing that data to insurers that use the common data to apply their own experience rating plans. This approach grants insurers independence from a common experience rating plan, but it maintains the common data base.
 - c. Abandon the use of common experience rating plans and common policyholder data bases. This approach provides maximum independence to insurers.
3. Classification independence
 - a. Permit insurers to subdivide NCCI classifications.
 - b. Permit insurers to use their own classification relativities.
4. Anniversary rating date rule--allow modifications to the rule.

SUMMARY

5. Individual insurer filing forms--require new filings when NCCI rates change.
6. Expense data--restrict the NCCI from the compilation and distribution of any expense information.

These areas are discussed below.

Components of loss costs

The typical loss cost system as presented in Chart 1 of the cover letter, provides that loss costs include adjustments for the following: loss development, trend, anticipated benefit levels, residual market subsidies, loss-based assessments, and loss adjustment expense. Although excluding adjustments for any of these items does not necessarily impair the system, the workers compensation rating system is complex, and all insurers may not be able to properly adjust for these factors. Even a small number of insurers improperly calculating loss costs could result in inadequate, excessive, or unfairly discriminatory rates.

These risks are greatest if adjustments for loss development, trend, anticipated benefit levels, and residual market subsidies are not included. Almost all loss cost systems allow the rating organization to include these adjustments.

Existing loss cost systems vary in their treatment of loss adjustment expense and loss-based assessments, but advisory organizations are generally permitted to include these factors in the advisory loss costs.

Premium-based assessments are generally excluded from loss costs.

Experience rating plan

The weight of history and the practice in loss cost states suggest that continuing a common centrally administered plan is desirable. The common plan may (1) encourage workplace safety in ways which may not be achieved through individual

SUMMARY

insurer action, (2) reduce policyholder confusion and (3) permit policyholders to compare their experience to that of other similarly-classified policyholders. The use of a common plan has been viewed as a way to achieve equity among policyholders. Moreover, if there were no common experience rating plan then there are technical issues related to the off-balance in the individual insurer experience rating plans which might affect loss cost adequacy. Further study of the effects seems desirable before taking action to replace a common plan with individual insurer plans.

However, permitting the use of approved individual insurer plans in addition to the common centrally-administered plan is an alternative that minimizes the potential disadvantages listed in the OBJECTIVES OF A LOSS COST SYSTEM section above. Insurer proposed and regulator approved rating plans would be designed to produce adequate and equitable rates. The process of calculating DSR premium would be similar to the process now required to calculate DSR premium when schedule rating is applied. Incentives for workplace safety would probably remain unchanged, because the NCCI common plan remains a factor in the policyholders premium. Control of cost and policyholder confusion would be in the hands of the insurer that proposes to use such a plan.

Classification independence

It is generally recognized that data accuracy is greatest when the data affects the insured's premium. From this perspective, maintaining the common experience rating plan helps to assure uniform classification coding.

Thus, if insurer classification definitions vary too far from the NCCI classification, there is an increase in the risk of classification errors.

In addition to the need for data accuracy in the experience rating plan, the NCCI ratemaking system requires that insurers convert their premium data to NCCI DSR level. This conversion process is critical to the accuracy of NCCI loss cost levels. Too much variation in definitions may affect insurer accuracy and limit the ability of NCCI to audit this process.

SUMMARY

By maintaining an enhanced NCCI field audit program it may be possible to better assure data accuracy under a flexible classification system. However, this will probably require increasing NCCI's role as a statistical agent. Specifically, NCCI enforcement authority may need to be increased, and increased costs may result.

Anniversary rating date rule

The anniversary rating date rule has two components:

1. The NCCI prepares experience rating modifications effective on the anniversary rating date, which approximates the policyholder renewal date.
2. The manual rates of the policyholder change only on the anniversary rating date, subject to the same flexibility now provided for in the NCCI Experience Rating Plan.

Item 1 is required to maintain a centrally-administered experience rating plan, while item 2 is a convenience in maintaining item 1. The anniversary rating date rule is assumed to apply when the NCCI calculates premium at current rate level. If the rule were totally eliminated, the NCCI would need to collect additional data and/or apply approximations to adjust for the change in procedure. Typically both parts of the rule are maintained in the system. This is the simplest process.

One alternative is the following: (1) experience modifications are promulgated at the anniversary rating date, (2) a policyholder can change insurers and obtain the benefit of the new insurer's rates for the period from the date the policy changed until the anniversary rating date, but (3) at the anniversary rating date, the insured's rates would change based on the revised experience modification and based on the new insurer's rates at the anniversary rating date. The policyholder receives the benefit of the new insurer's rates at the transfer date for the short-term period until the anniversary rating date.

SUMMARY

Filing forms

Potential regulatory delay, with resulting inaccuracies in rate levels, makes it undesirable to require companies to file a revised form with every NCCI loss cost change.

The automatic process also simplifies the designated statistical reporting (DSR) process for data reporting. If insurer premiums do not change at the same date that the NCCI loss costs change, then the insurer must do a special conversion of premium to DSR level for the short time period until a uniform, or nearly uniform, relationship to the new NCCI loss costs is reestablished.

Distribution of expense data

The individual workers compensation loss cost states have not addressed the role of the advisory organization in the compilation and distribution of expense information. The system approved for ISO lines of insurance permits ISO to distribute historical factual expense information. We propose that NCCI be permitted to proceed as follows:

1. Collect historical general and other acquisition expense data from insurers.
2. Adjust the data to a common basis with respect to policyholder premium size distribution, residual market servicing carrier fees, and variations in rate level.
3. Summarize the adjusted expense data into groups such as stock insurer, non-stock insurers, national insurers, regional insurers, small insurers, and large insurers.
4. Distribute that information to insurers, regulators, and others.

SUMMARY

The disadvantage of this approach is that the NCCI appears to maintain a role in insurer expense analysis. The advantages are that the adjusted data is more meaningful than publicly available expense information, and the comparative data would be useful to regulators as well as insurers in evaluating the reasonableness of an insurer's filed loading factor.

With regard to this issue, it is important to note that regardless of the NCCI expense role in the voluntary market, the NCCI appears to maintain a role in insurer expense analysis because of its involvement in the residual market system. Overall, we conclude that the benefits of the distribution of this historical information outweigh the disadvantages. ISO also plans to distribute historical expense information.

Studies of expense by size of policyholder

Objective studies of general and other acquisition expenses by size-of-risk are likely to be available to regulators and insurers only if historic information is collected, analyzed, and distributed by the NCCI. If multi-company studies of expense by size of risk are not available to insurers and regulators, then it is likely that insurer operating expense discounts will become more market-driven rather than cost-driven. In the typical system, the NCCI would continue conducting these studies and make the information available to insurers and regulators

Distribution of premium tax and assessment information

In the typical system, this would include historical and factual information on premium tax levels and assessment levels in the state, and how the assessments are handled in the loss costs.

SUMMARY

TRANSITION ISSUES

To minimize the costs and confusion associated with the transition to loss costs, we suggest the following:

1. There should be as much consistency as possible in the loss cost implementation procedures among states.
2. Consideration should be given to deferring the transition to a loss cost system until ISO has completed its own program of loss cost implementation for other property and casualty lines; late 1992 or early 1993 was suggested by many of those we interviewed during this examination.
3. The transition should coincide with the NCCI's usual state rate review schedule.
4. The implementation procedures should include an educational effort by the NCCI and perhaps other interested organizations for the affected parties. This would include regulatory personnel, insurer personnel, and agents/sales representatives. The timing for loss cost implementation should allow for this educational effort.

REPORT STRUCTURE

Chapter 1 discusses the issues related to loss costs identified in our interviews, reviews of testimony, and other research. Chapter 2 describes current NCCI rate-related procedures in administered-pricing states. Chapter 3 describes NCCI and independent rating (advisory) organization rate-related procedures in loss cost states. Chapter 4 covers loss cost procedures implemented or under consideration by ISO. Based on the issues identified in Chapter 1 and our analysis in Chapters 2, 3, and 4, we evaluate alternative components of loss cost systems in Chapter 5.

SUMMARY

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM

1. The NCCI files loss costs with provisions for:
 - a. Prospective losses by classification which reflect loss development, trend, and anticipated benefit levels
 - b. Assigned risk subsidies to be paid by the voluntary market
 - c. Loss-based assessments
 - d. Loss adjustment expense
 - e. Disease loss components
2. The NCCI distributes information relating to its loss cost calculations including (1) alternative approaches for loss development and trend, (2) information on benefit change calculations, (3) information on judgmental decisions such as classification relativity capping, (4) the difference between voluntary and residual market experience overall (and by classification, if relevant), etc.
3. The NCCI also distributes historical and factual information with regard to:
 - a. Premium taxes
 - b. Assessments
 - c. Historical information on other insurer operating expenses with appropriate categorization and adjustment for policyholder size and assigned risk service expense considerations
 - d. Premium comparisons

SUMMARY

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM (CONT.)

3. (Continued)
 - e. Individual insurer loss experience compilations
 - f. Expense studies by size of policyholder
4. The NCCI administers an Experience Rating Plan, which is common to all policyholders within a state.
5. The anniversary rating date rule continues.
6. Existing state limitations on individual insurer independence with respect to classification definitions and relativities are continued.
7. The NCCI committees of insurers become advisory.
8. The Classification and Rating Committees continue to assist in adjudicating questions of class definitions and other roles permitted by the state regulator.
9. The NCCI continues to establish residual market plan manual rates.
10. For the voluntary market, the NCCI no longer files:
 - a. Provisions for expenses related to premium tax, production, and general overhead
 - b. Provisions for profit and contingencies
 - c. Expense constants

SUMMARY

CHART 1

ELEMENTS OF THE TYPICAL LOSS COST SYSTEM (CONT.)

10. (Continued)
 - d. Premium discounts
 - e. Minimum premiums
11. The NCCI adjusts rating plans, where necessary, to exclude expenses as noted above. The relevant plans pertain to experience rating, retrospective rating, schedule rating, excess loss rating for employers liability, and other miscellaneous rating items.
12. State regulators, using the NCCI as their statistical agent, develop rules and procedures to maintain and improve the level of data accuracy and availability. This might include increases in field inspections and verification of insurer reported data.
13. Filing procedures for individual insurers are streamlined in a manner analogous to the ISO process, including standardized filing forms appropriate for workers compensation insurance and loading factors that remain in effect until changed by the insurer or disapproved by the regulator.
14. Schedule rating is permitted or not permitted based on current state law and regulation. Where schedule rating is permitted, NCCI filings could include schedule rating, but individual insurers could file independent schedule rating plans.
15. State rating laws remain basically unchanged. Prior approval laws continue to be administered as prior approval for NCCI loss cost filings and for individual company loading factors or other deviations from NCCI advisory material.
16. NCCI continues its other field operations work and its role in maintaining policy forms.

CHAPTER 1

Identification of Loss Cost Issues

In this chapter, we identify issues of importance to various participants in the workers compensation system: insurers, regulators, agents/sales representatives, policyholders, and others. To obtain input from those groups, we reviewed testimony already provided to the NAIC, interviewed additional individuals, and obtained written material from various groups. Appendix A lists the sources of information for this portion of the examination.

Issues associated with the implementation of a loss cost system for workers compensation insurance are similar but not identical to the issues associated with the implementation of loss cost systems for other property/casualty lines of insurance.

The issues can be divided into the following categories:

- I. THE RATING ORGANIZATION
- II. INSURERS
- III. AGENTS/SALES REPRESENTATIVES
- IV. INSURANCE REGULATORS
- V. OTHER ISSUES

The remainder of this chapter is a discussion of these issues.

CHAPTER 1

Identification of Loss Cost Issues

I. THE RATING ORGANIZATION

The current activities of the NCCI which may be affected by the transition to loss costs are discussed below.

A. Material filed by the rating organization

Under a loss cost system, the rating organization files for the loss cost portion of the rate, not the gross rate. The portion of the rate for which the rating organization is responsible could include the following:

- a. Historical losses
- b. Analysis of loss development
- c. Analysis of trend
- d. Adjustments to current benefit level
- e. Residual market subsidies to be paid by voluntary market policyholders
- f. Loss-based assessment provisions for costs such as second injury funds and other special funds, and workers compensation board costs
- g. Loss adjustment expenses
- h. Disease element loss costs
- i. Premium-based assessments for items similar to those listed in item f

These items are discussed in greater detail in Chapter 2.

CHAPTER 1

Identification of Loss Cost Issues

In addition to gross rates by classification, NCCI filings currently include minimum premiums, premium discount plans, schedule rating plans (applicable in some states), an experience rating plan, retrospective rating plans, other rating plans, expense constants, anniversary rating date rules, and other rating rules. Some or all of these items may continue to be filed by the NCCI in a loss cost state.

B. Role of NCCI staff

Decision-making

In the workers compensation administered-pricing states listed in Chapter 2, insurer personnel serve on committees which are directly involved in making decisions concerning the development and filing of rates.

In a loss cost environment, it is generally assumed that insurer committee decision-making is eliminated. This is the case for ISO, and also applies to NCCI ratemaking in open competition states. In these situations, the rating organization staff makes the decisions. Insurer personnel are available to provide technical guidance and professional (not business) advice to the rating organization staff.

Thus rating organization staff might become responsible for decision-making in the following areas:

- Preparation of prospective loss costs
- Filing, negotiation, and refiling of loss costs with insurance regulators
- Development of classification definitions and relativities
- Rating plans including the Experience Rating Plan

CHAPTER 1

Identification of Loss Cost Issues

Distribution of information

In a loss cost system, the rating organization may become responsible for distributing information such as (1) loss cost filings; (2) summaries of expense information for use by insurers, regulators, and others; (3) comparative rate and rating plan information; (4) special studies of the workers compensation system; and (5) evaluations of actual or potential benefit changes.

This information could be made available to a narrow audience--member insurers and regulators on request--or to a broader audience, potentially including any entity requesting and willing to pay for the information, but subject to appropriate confidentiality on individual insurer or policyholder data.

NCCI structure

Some changes in NCCI funding may be desirable. NCCI is funded primarily by premium-based assessments of insurers, which differs from the situation at ISO, where over 70% of financing is from fees for specific services. The assessment process is most suitable for an organization providing similar services to all members, with essentially mandatory membership. If members are allowed to vary their practices from the NCCI's approach, and if NCCI staff is to operate more independently of NCCI's member/owner insurers, then it may become increasingly desirable for financing to be more service-related and less assessment-based. Obviously, the service charges should be structured to enhance competition. More financial independence is also desirable if the NCCI is responsible for providing data to entities other than regulators and member insurers.

In addition to financing issues, the NCCI has testified that it intends to amend its Constitution to permit public representation on its Board. ISO already has one public member on its Board.

CHAPTER 1

Identification of Loss Cost Issues

Within the NCCI structure, the issue arises whether the NCCI should rearrange priorities, e.g., put less emphasis on insurer profitability issues and more on research and benefit pricing. It is not clear how a loss cost environment will change the relative need for various NCCI services. As the loss cost system evolves, NCCI must be alert to the need to redirect efforts appropriately. Changes in NCCI organization and committee structure may be needed.

II. INSURERS

The activities of insurers will be expected to change with the transition to loss costs. Below, we identify the major issues.

A. Degree of independence permitted individual insurers

Currently permitted independence

In administered-pricing states, the NCCI files rates and rating plans on behalf of all insurers. Depending on state law and regulations, individual insurers are permitted one or more of the following:

1. Uniform deviations from NCCI rates for all classifications
2. Schedule rating which adjusts rates for individual policyholders
3. Policyholder dividends

Individual insurer variations from NCCI classifications are not generally permitted.

In a loss cost system, individual insurers may be limited to the same level of flexibility available in an administered-pricing state, i.e., deviations, schedule rating,

CHAPTER 1

Identification of Loss Cost Issues

and policyholder dividends. Alternatively, a loss cost system could be more flexible and allow variations in classification relativities, classification definitions, experience rating, and other rating plans. Some of these variations are discussed below.

Variations in classifications

In establishing a loss cost system, there are two fundamental areas of classification rating that require decisions: variations in classification relativities, and variations in classification definitions.

The current common practice in prior-approval loss cost states is to allow rate deviations (varying multipliers) in only a limited number of classes and few new classifications. Some states require that insurers provide support for the deviation, while others allow more freedom.

It is a common practice in open competition states to allow greater freedom in classification relativities and definitions. In administered-pricing states, the common practice is to permit no variation from NCCI classifications.

Regardless of the classification relativity or definition used by the insurer, the insurer is required to report exposure, premium, and claim experience using NCCI classification definitions and to adjust premiums to the NCCI Designated Statistical Reporting (DSR) level (i.e., the standard rates, advisory rates, or loss costs appropriate in the state). Where rate deviations by class are allowed, the conversion to the NCCI DSR level may not be accurately accomplished.

This requirement that an insurer provide data on the NCCI classification basis, even if the insurer uses a different pricing system, varies from the procedure used in other lines of insurance. In most lines of insurance, insurers report statistical data in a manner consistent with their pricing plans. However, in workers compensation, it is the use of a common experience rating plan that requires insurers to convert their own classification definitions to those of the NCCI. Allowing insurers to create

CHAPTER 1

Identification of Loss Cost Issues

variations in classification definitions introduces a risk to the quality of data used for experience rating, classification ratemaking, and overall cost level calculations.

Variations in experience rating

A fundamental facet of the workers compensation system is the current use by all insurers of a common experience rating plan centrally administered by the NCCI and independent state rating and advisory organizations. Under this system, all insurers apply the same modification factor to a policyholder.

The use of a common experience rating system is considered important because it is intended to encourage policyholder loss prevention in ways which may not be achievable by individual insurer action. It is also argued that the use of a mandatory common experience rating plan is more equitable to policyholders than the insurer-designed voluntary experience rating plans used in other lines of insurance.

The use of a common, centrally-administered plan requires that all insurers report data to the NCCI on a common classification basis. Furthermore, such a plan requires that the NCCI collect individual policyholder data and maintain premium and claim data in the same database. If a common experience rating plan were not continued, the NCCI could maintain separate premium and claim databases, a simpler task than maintaining the current common database.

Accuracy at an individual policyholder level is critical for experience rating calculations; any errors arising in the experience rating process from variations in classifications from insurer to insurer are therefore significant. For classification and overall ratemaking, however, errors in a small number of individual policyholder situations are not usually material to the ratemaking process. Thus, the need to maintain common classifications is reduced if a common, centrally-administered experience rating plan is abandoned.

CHAPTER 1

Identification of Loss Cost Issues

The experience rating plan issue does not arise in the ISO context because (1) plans for ISO lines have generally been voluntary, (2) the plans are applied by insurers rather than ISO, and (3) the plans apply to fewer policyholders.

In workers compensation loss cost states, the use of a common, centrally-administered plan is generally mandatory. Only Michigan permits variations in the experience rating plan.

B. Structure and content of insurer filings

In administered-pricing states, individual insurers are not required to make any workers compensation filings if the insurer intends to follow the NCCI rates. Furthermore, if an insurer chooses to file a deviation from NCCI rate levels, that deviation generally remains in effect until the insurer files a new deviation, regardless of whether the NCCI rates change in the interim.

Loss cost filings

In a loss cost system, all insurers must, at a minimum, file for a loading factor which is applied to NCCI loss costs to produce manual rates. Individual insurers must also file other expense-related rules such as minimum premiums. Depending on the degree of flexibility permitted, insurers may need to file additional rating rules and rating plans.

Filing form

For the loss cost system applicable to ISO lines of insurance, the NAIC has prepared a standard form. In this form, the insurer refers to the ISO loss cost circular and adds its own expense and profit provisions, and perhaps loss deviations. The form requires support for the provisions proposed by the insurer, and is structured so that

CHAPTER 1

Identification of Loss Cost Issues

an insurer can either have it apply only to the most current revision or to future revisions until the form is resubmitted.

In a workers compensation loss cost system, a comparable form is desirable to simplify the insurer preparation and regulator review of individual insurer filings. However, changes to the ISO form are necessary, since workers compensation filings must address issues which are not part of the ISO form. These issues are described below.

First, the standard workers compensation rating system includes the use of expense constants for small risks. A provision in the form to show the proposed insurer expense constant, its justification, and the effect on the insurer expense loading would be desirable.

Second, the workers compensation manual rate structure includes a premium adjustment for expenses by size-of-risk. To determine manual rates for workers compensation, it is necessary for the insurer to consider and file information related to both its overall average expenses for all policyholders and the effect of its premium discount and expense constant programs on the manual rate. The average expense information is required to establish the overall loading factor and to allow the regulator to examine the profit level implied by the loading factor. The effect of the insurer's premium discount and expense constant programs is needed to calculate the loading to be applied to manual loss costs to produce rates which yield the target overall loading factor. The current form for ISO lines of insurance does not consider information of this type.

Third, the ISO form does not elaborate on the insurer's development of its profit provision. The investment income potential for workers compensation is more significant than for many ISO lines of insurance; treatment of investment income on the filing form may thus be desirable. Standardization in the investment income area may be difficult, however, because of the wide variations in state practices.

CHAPTER 1

Identification of Loss Cost Issues

Fourth, depending on how assessment provisions are handled in the loss costs, the individual insurer filing should show how those assessments are treated in the proposed rates.

Finally, the NCCI loss costs include an off-balance for the average effect of experience rating plan modification factors. If insurers are permitted to use their own experience rating plans, separate identifiable adjustments for the plan off-balance for each insurer would be appropriate. ISO requires no such adjustment because the ISO experience rating plan off-balance is assumed to equal to unity for manual ratemaking purposes.

Benefit changes

In a workers compensation system, consideration of benefit changes is required. For most property casualty insurance policies, contractual coverage seldom changes during the term of the policy. In workers compensation insurance, however, changes in benefit level occur regularly, either due to legislative action or to automatic adjustments built into the benefit structure. These adjustments are typically effective based on the date of the accident; thus, these benefit changes affect in-force policies. In the current workers compensation system, the NCCI files for changes to in-force policies when there is a significant benefit change, and the change is accomplished by filing a table of premium adjustment factors which vary by policy effective date.

A loss cost system should accommodate this aspect of workers compensation coverage. Presumably, the NCCI will evaluate the effect of benefit changes on loss costs and prepare the appropriate loss cost filings, including the appropriate loss cost adjustment factors for in-force policies.

CHAPTER 1

Identification of Loss Cost Issues

Regulatory compliance

Two concerns regarding regulatory compliance are potential delays and insurer costs. The extent of regulatory delay depends significantly on the details of the filing process, and particularly on whether insurer rate changes happen automatically with NCCI changes or require individual insurer action.

The costs of regulatory compliance also depend on the details of the process. The expenses of rate filings are now largely included in NCCI costs. The NCCI prepares filings, supplemental supporting information, and expert testimony, and supplies legal representation and expert witnesses. The increase in insurer expenses related to filings in loss cost states will probably not be major if (1) the NCCI continues to bear the costs of achieving approval for the loss cost portion of the rate and (2) insurer filings are generally approved without significant regulatory proceedings. If insurers are required to regularly defend their individual filings in independent regulatory proceedings, compliance costs will increase.

C. Other impacts on insurer practices

Dividend plans

Dividend plans are not necessarily affected by the change to a loss cost system; however, some changes can be reasonably expected. The extent of these changes depends in part on the purpose of the dividend plan from the insurer's viewpoint.

Dividend plans serve varying purposes. For one type of dividend plan, the aim is to return expense savings to policyholders; this type would disappear to the extent that expense savings are reflected in individual insurer loading factors. Another type is intended to provide groups of policyholders a dividend based on better-than-expected loss experience for the group, essentially acting as a group retrospective rating plan. This type is likely to continue unless group retrospective rating arrangements are permitted. Finally, differences in loss costs between individual

CHAPTER 1

Identification of Loss Cost Issues

insurers and the NCCI-approved average loss costs may be treated differently by different insurers. Some may choose to reflect expected differences in the loss cost loading factor, and others may choose to wait until actual results are available and reflect the differences in dividends. Overall, some reduction in dividends is likely.

Changes in dividend structure may produce changes in insurer marketing strategies. In ISO lines, the introduction of loss costs does not change the basis on which insurers compete. However, for workers compensation prior to loss costs, dividend plans may have been a focus of competition. After loss costs, even with minimal pricing freedom, the focus of price competition is likely to shift toward initial cost based on the loading factor, and away from dividends.

Insurer-agent/sales representative communications

Insurers will need to communicate their rate levels to their agents/sales representatives; this could be done by manual rate pages or other means. This is discussed further in the next section.

III. AGENTS/SALES REPRESENTATIVES

The two major issues directly affecting agents/sales representatives are issues that also affect other participants: (1) how the loss cost system will affect the agents/sales representatives' ability to communicate efficiently with insurers and policyholders, and (2) the extent to which the loss cost system might reduce the number of insurers willing to provide workers compensation coverage.

A. Communication

In other lines of insurance, insurers and agents/sales representatives have varying methods of communicating loss cost information. These methods include agents/sales representatives receiving the ISO loss cost manual, agents/sales

CHAPTER 1

Identification of Loss Cost Issues

representatives receiving individual insurer loading factors and instructions on the application of those factors to the loss costs, agents/sales representatives receiving insurer manuals containing insurer final rates, and agents/sales representatives using computer rating systems developed by computer service bureaus.

For workers compensation, the possible means of communication are the same, except that there is currently no significant computer rating service market. If there were significant variation in rates and/or rating approaches between insurers, computer rating services for workers compensation might emerge.

Agents/sales representatives use rate vendor services not only to obtain individual policyholder premium quotes, but also to obtain information regarding the market level of rates and to identify unreasonably high or low rates. For workers compensation, that process has been relatively easy when insurers are limited to uniform deviations, individual risk schedule rating modifications, and policyholder dividends. If increased individual insurer variability is permitted, the need for comparative rating services may be increased.

B. Interstate risks

Workers compensation involves interstate risks at least as often as other lines of insurance. Therefore, for agents/sales representatives as well as insurers, standardization of approaches across states is important. Since the workers compensation system includes independent workers compensation rating/advisory organizations in many of the largest workers compensation states, it may be more difficult to achieve standardization in workers compensation than in the ISO lines of insurance. While the current system is not standardized, implementing loss costs may make standardization even more difficult.

CHAPTER 1

Identification of Loss Cost Issues

C. Market concentration

There is concern that the additional complexities of dealing with a loss cost environment will reduce the number of insurers providing workers compensation coverage. This can affect agents/sales representatives, policyholders, and others. The effect of loss costs on market concentration may be different in smaller states than in larger states. Analysis of this issue is beyond the scope of this study.

IV. INSURANCE REGULATORS

From a workload perspective, the issues discussed in section II.B above with respect to the content of insurer rate filings will also have a significant effect on the regulatory workload.

The overall regulatory objectives of a loss cost system can be viewed as those expressed in the Alternative Model Workers Compensation Competitive Rating Act. These are as follows:

1. To prohibit price-fixing agreements and other anti-competitive behavior by insurers.
2. To protect policyholders and the public against the adverse effects of excessive, inadequate, or unfairly discriminatory rates.
3. To promote price competition among insurers, thus providing rates responsive to competitive market conditions.
4. To provide regulatory procedures for the maintenance of appropriate data reporting systems.
5. To improve the availability, fairness, and reliability of insurance.
6. To authorize essential cooperative action among insurers in the

CHAPTER 1

Identification of Loss Cost Issues

ratemaking process and to regulate such activity to prevent practices that tend to substantially lessen competition or create a monopoly.

7. To encourage the most efficient and economic marketing practices.

Our evaluation of a reasonable loss cost system is based on these criteria.

V. OTHER ISSUES

Other issues which are affected by loss costs concern transitional issues, data quality, the impact on the residual market plans, the potential for needed changes to the Insurance Expense Exhibit, and other issues.

A. Transitional issues

Timing

The foremost transitional issue is timing. Many are concerned that a change to workers compensation loss costs while ISO is completing its transition will create problems for agents/sales representatives, regulators, and insurers. There is some degree of consensus from within the industry that it would be desirable for workers compensation loss costs to begin after ISO is essentially through its transition for the currently scheduled lines of business. This would mean beginning in late 1992 or early 1993.

The reasons for waiting include the fact that attention by insurer, agent/sales representative, and regulator personnel is required for the ISO transition, and multiple transitions may be too much to handle. Furthermore, some expressed the view that it would be desirable to allow ISO to resolve potential problems with the system before introducing it to workers compensation.

CHAPTER 1

Identification of Loss Cost Issues

It is also considered important that the transition occur in a phased manner like the ISO transition, rather than by converting all rates to loss costs at a single date.

Education

The second transitional issue is education for agents/sales representatives, insurer personnel, regulators, and others. To some extent, these groups will have been educated to the requirements of a loss cost system through the ISO conversion. However, the current workers compensation system is different from the pre-loss cost ISO system, and the workers compensation loss cost system is also likely to differ from the ISO loss cost system. Therefore, an active education process by the NCCI, at least at the level of the ISO education process, is reported desirable.

Use of rate freedom

It remains uncertain how quickly, if at all, insurers will use the rating freedom given to them under the provisions of a loss cost system.

B. Data quality

The issue of maintaining data quality was mentioned by most of those we interviewed as being one of their greatest concerns in the loss cost transition for workers compensation.

Data accuracy for individual policyholders is critical for a centrally-administered experience rating system. A loss cost system does not necessarily disrupt that process; however, depending upon the degree of independence available to insurers, the loss cost system does put additional burdens upon the system.

With respect to overall loss cost levels, the accuracy of the NCCI procedures depends on insurer compliances with the Designated Statistical Reporting (DSR)

CHAPTER 1

Identification of Loss Cost Issues

level rules for premiums. The greater the insurer independence, the greater the chance for inaccuracies in the process.

The anniversary rating date rules are also relied upon in the NCCI calculation of earned premium on current level. If the rule is eliminated, additional data or approximate methods will be needed. In the long run, the NCCI may need to change its approach to obtaining premium at current rate level in order to rely less on insurer calculations (DSR) and policy writing rules (anniversary rating date rules).

For classification relativities and experience rating values, the accuracy with which insurers define classes and convert them back to NCCI classifications is important. For reasons including the use of a common experience rating plan, the NCCI has probably been more attentive to classification assignments than is true for other lines of insurance. Changes to the system may reduce the homogeneity of classification data.

In general, it should be recognized that exceptions which can be readily accommodated on a state exception basis become more difficult in a national system.

In addition, the impact on the database will depend on the manner in which loss costs are implemented.

C. Management of residual market plans

The residual market plans are now administered through the NCCI. In administered-pricing states, insurer committees have the decision-making responsibility for residual market plans, including the development of final gross rates. In advisory rate and loss cost states, insurer committees have largely removed themselves from residual market plan decision-making.

CHAPTER 1

Identification of Loss Cost Issues

ISO is moving towards an environment where it will no longer be involved in any gross rate promulgation, voluntary or involuntary. All ISO activity will be limited to loss costs. This is feasible for ISO, because there are separate organizations like Automobile Insurance Plans Service Office (AIPSO) that handle residual market rate filings. This may be desirable for public relations purposes as well as for the purpose of encouraging greater competition. As long as the NCCI is involved with residual market gross rate levels however, the ISO-type separation will not be achieved for workers compensation. The role of NCCI committees in the residual market process may need to be carefully separated from the role of the committees as advisors in voluntary loss costs.

D. Insurance Expense Exhibit data

Currently, Part III of the Insurance Expense Exhibit (IEE) requires insurers to adjust net earned premium to a standard premium basis by adding premium discounts and retrospective rating adjustments. By making these adjustments, premiums for all insurers are intended to be on the same level.

With loss costs, insurers are required to report "premium" at the DSR level in NCCI data calls. If "Standard Premium" were replaced by DSR premium for the purposes of the IEE, a uniform level of data would be available when, if ever, all states are on a loss cost basis. At best, the value of this portion of the IEE will be uncertain for several years. Very likely, this portion of the IEE will never accomplish the purpose it had when essentially all states were subject to administered-pricing systems without deviations. Considering that the NCCI may be permitted to collect and distribute more meaningful data, the NAIC should consider eliminating the section.

CHAPTER 1

Identification of Loss Cost Issues

E. Other perspectives

Some of the comments from the perspective of labor, the general public, and others both inside and outside of the insurance industry follow:

1. Will loss costs really result in increased competition and a reduction in rates? Arguments vary on this issue.
2. Some say that the full benefit of a loss cost system will not be achieved unless the rating organizations are limited to historical loss costs (consideration of trend, loss development, and the like would be the responsibility of individual insurers) and totally removed from the expense issue (no publication of expense information).
3. Will the loss cost system result in fewer insurers and more concentration of the market share by the larger insurers?
4. Will a loss cost system increase the cost of doing business and therefore increase the cost to the policyholder? There are no reliable estimates of the additional cost. The magnitude of any such costs will depend on details of the process by which loss costs are regulated.
5. With increased competition and perhaps lower premiums, will insurer safety activities be reduced, to the disadvantage of workers? Similarly, will changes to the Experience Rating Plan, if any, reduce policyholder incentives for reducing workplace injuries? Unlike the systems in which ISO is involved, the workers compensation system evolved with the intent of encouraging worker safety as well as policyholder financial security.
6. The workers compensation system is under a variety of strains, as evidenced by the increasing residual market, the size of requested rate level changes, and the legislative attention to proposed changes. The loss cost system is not

CHAPTER 1

Identification of Loss Cost Issues

seen as a way to deal with any of these problems. The real problems, some say, include increasing attorney involvement, increasing health costs, inappropriate benefit structures, and erosion of the exclusive remedy rule.

7. Should there be more freedom in rating for large policyholders than for smaller policyholders? It is difficult to separate large from small, but more freedom might reduce the pressure to self-insure.

These issues are generally beyond the scope of this study.

CHAPTER 2 Current NCCI Rate-Related Procedures

This chapter describes the services the NCCI provides to its member companies in the traditional prior-approval, administered-pricing environment. This applies to the following states:

Alabama	Mississippi
Alaska	Missouri
Arizona	Montana
Colorado	Nebraska
District of Columbia	New Hampshire
Florida	Oklahoma
Idaho	South Dakota
Iowa	Tennessee
Kansas	Utah
Maine	Virginia

Procedures in independent bureau states with administered pricing systems are generally similar, but the scope of the study did not require a state by state analysis of the differences. In open competition and loss cost states, the procedures will vary from those described in this chapter. Chapter 3 discusses the main variations. This chapter contains the following sections:

- I. RATE COMPONENTS AND RULES
- II. COMMITTEE ROLES
- III. DISTRIBUTION OF MATERIAL TO AGENTS/SALES REPRESENTATIVES
- IV. RELATIONS TO REGULATORS
- V. POLICYHOLDER SERVICES
- VI. DATA COLLECTION

CHAPTER 2

Current NCCI Rate-Related Procedures

I. RATE COMPONENTS AND RULES

The NCCI rates and rules in administered-pricing states generally determine the premium the policyholder will pay for its coverage, subject to the degree of independence permitted to individual insurers by state law or regulation. The sections below discuss how NCCI filings consider the following: (A) Rates; (B) Expense constants; (C) Premium discounts; (D) Minimum premiums; (E) Anniversary rating date rule; (F) Experience rating plan; (G) Retrospective rating plans; (H) Schedule rating plans; (I) Other rating plans; (J) Policyholder dividend plans and practices; (K) Rate changes for policies in effect; (L) Retroactive rate changes; (M) Distribution of expense information to insurers; (N) Employers liability increased limit percentages; (O) Loss constants; and (P) Residual market classification relativities.

A. Rates

Rates are subject to prior approval and are filed by NCCI on behalf of insurers. The rates the NCCI files in these jurisdictions contain allowances for all losses, expenses, and profit. Specifically, they include the following categories:

Provisions for losses

Workers compensation losses consist of the indemnity and medical benefit payments to injured workers and their healthcare providers for covered injuries. They also include reserves for anticipated future payments for accidents which have occurred. For purposes of ratemaking, there are three major adjustments to losses reported as of a given date.

Loss development

Workers compensation claims take time to settle, pay, and close. As a result, the losses reported under the statistical plan and in the financial data calls are often

CHAPTER 2

Current NCCI Rate-Related Procedures

estimates. Loss development factors adjust the reported losses by the observed historical pattern of the changes in prior loss estimates.

Benefit level changes

Workers compensation losses are governed by the statutory provisions contained in each state's workers compensation act. The benefits under these statutes often change automatically through indexed provisions or amendments. Consequently, historical losses may be adjusted by the average impact of benefit changes contained in the workers compensation act. The NCCI reviews these legislative changes and calculates factors representing their average impact.

Trend

The trend factor adjusts the historical workers compensation losses for expected cost changes over and above the expected changes in the exposure base. The exposure base for workers compensation is generally total payroll, which increases (decreases) yearly by changes in wage rates and employment levels. Thus, workers compensation premiums are indexed to payroll changes.

Provision for Expenses

The expense categories of production; general; and taxes, licenses, and fees are included in the rates.

Production expenses

These are all expenses relating to the production of insurance premiums. They include commission and brokerage and other acquisition expenses, and are usually included as 15% of the manual rate. Premium discounts will reduce this expense

CHAPTER 2

Current NCCI Rate-Related Procedures

percentage for premiums in excess of \$5,000. Premium discounts are discussed in greater detail below.

General expenses

These expenses are for the general operations of the insurers, other than production and claims. The NCCI's Actuarial Committee annually recommends a provision for these expenses after reviewing countrywide experience. Premium discounts reduce this expense percentage for premiums in excess of \$5,000, based on periodic countrywide multi-insurer size-of-risk expense studies.

Taxes, licenses, and fees

These expenses usually consist of the premium tax in each state, premium-based assessments, and taxes such as industrial commission taxes, second injury assessments, and guaranty fund assessments. They also include miscellaneous fees such as insurer licensing fees, rate and policy form filing fees, agency licensing fees, and the policyholder share of employee Social Security taxes. This expense component is not reduced through the application of premium discounts.

Profit and contingencies

This is a provision for underwriting profit and contingencies. Traditionally, the NCCI requests 2.5% of premium for this provision. The NCCI maintains that this is a reasonable value for underwriting profit and contingencies, after the consideration of investment income.

However, this item is often adjusted downward, sometimes to negative values, in response to alternate calculations of the consideration of investment income. The profit and contingency allowance is not adjusted by the premium discount program.

CHAPTER 2

Current NCCI Rate-Related Procedures

Loss adjustment expenses

Loss adjustment expenses are considered in the final rates through a factor applicable to losses alone. The NCCI's Actuarial Committee annually reviews and recommends a loss adjustment factor after a review of countrywide Insurance Expense Exhibit loss adjustment expense averages.

Loss-based assessments

Certain loss-based assessments are included directly in the definition of losses collected by the Statistical Plan and under the financial data calls. Other loss-based assessments are calculated and applied to the losses as a factor.

Disease elements

Some classifications contain extra amounts which are added to produce the final rate. Disease elements recognize the impact of special disease limitations introduced in the ratemaking process, the extra hazard implicit in the multiple-occurrence nature of these losses, and the fact that the long latency period associated with many occupational diseases may result in the exclusion of these losses from the classification data.

B. Expense constants

The expense constant, \$140 in current NCCI filings, is a flat charge added to the premium otherwise produced, and is designed to recognize a minimum expense amount common to all policyholders regardless of premium size. It thus recognizes the fixed elements of general and other acquisition expenses. The expense constant is determined through an NCCI special study by size-of-risk, usually performed once every five years. Between studies, the expense constant is adjusted by inflationary factors. The expense constant is added once per policy.

CHAPTER 2

Current NCCI Rate-Related Procedures

C. Premium discounts

The NCCI promulgates two tables of premium discounts: a stock table and a non-stock table. In each state, an insurer may use either table regardless of whether it is legally structured as a stock, mutual, reciprocal, etc. Generally, an insurer must notify the NCCI of its decision and must use the selected premium discount table on all policies it issues.

Premium discounts recognize that the expenses of insurers do not increase directly with increases in premium volume. Instead, they result in reduced percentage allowances for commission and brokerage and other acquisition and general expenses at higher layers of premiums. The non-stock premium discounts are determined by an NCCI committee and are based on judgement.

For other acquisition and general expenses, the stock premium discount table is based on the same special study of expenses by size-of-risk as the expense constant. Other portions of the discount program are based on judgement.

D. Minimum premiums

The NCCI Basic Manual also provides for minimum premiums. If the premium for a policyholder as otherwise determined by the rates and rules is below the minimum premium, the minimum is charged. The NCCI publishes minimum premiums by classification in each of the administered-pricing states. In general, the minimum premium is calculated as a multiple of the rate designed to represent the annual premium for one average worker. The expense constant is then added. Typically, the minimum premium resulting from this formula is limited to a minimum and maximum amount before publication on the rate pages. When the minimum premium changes, current ratemaking procedures contain an offset to the rates so that this change does not produce additional premium.

CHAPTER 2

Current NCCI Rate-Related Procedures

E. Anniversary rating date rule

The Basic Manual contains a rule stating that if a policy is canceled and then rewritten, the rates, rules, and experience modification factor in effect at the beginning of the original policy period are applicable to the rewritten policy. The NCCI or other rating bureau can reestablish the anniversary rating date.

F. Experience rating plan

The NCCI publishes and administers an Experience Rating Plan mandatory for all eligible policyholders. The rules of this plan are contained in the Experience Rating Plan Manual. The experience of all policyholders is reported to the NCCI by insurers according to the Statistical Plan. The NCCI's experience rating formula compares the individual experience of each policyholder to the average experience expected for similar policyholders, and results in an experience modification factor. In general, a three-year period expiring one year prior to the effective date of the new policy is used, although the rules provide for shorter or longer periods in certain circumstances. Factors greater than unity increase the policyholder's premium, whereas factors lower than unity decrease it. All insurers follow the uniform plan, and a single experience modification factor is issued regardless of the insurer writing the policy. In general, the experience is combined for policyholders with operations in more than one state or with more than one insurance policy.

G. Retrospective rating plans

Five retrospective rating options are published by the NCCI. Retrospective rating is optional for eligible policyholders, subject to insurer and policyholder agreement. Generally, only large-premium-sized policyholders are eligible (eligibility starts at \$5,000 in standard premium). Under retrospective rating, the premium charged to a policyholder depends on the actual loss experience that emerges under the policy. A minimum and maximum premium is agreed on, expressed as a percentage of standard premium. Within the minimum and maximum, the premium is based on

CHAPTER 2

Current NCCI Rate-Related Procedures

the loss record of the policyholder, multiplied by an expense factor.

The first four plans are called tabular plans. The minimum and maximum premium factors are pre-determined based on the expected loss size of the policyholder, and the other parameters of the plan are contained in a table based on these pre-determined minimum and maximum premiums. The fifth plan is more complicated because it allows different combinations of maximum and minimum premiums to be selected. All retrospective rating options automatically include the standard expense provisions and premium discount plans.

H. Schedule rating plans

In twelve states NCCI files a schedule rating plan, in which the premium for a policyholder may be modified in accordance with the filed plan based on individual risk characteristics. There is a minimum and maximum charge or discount for each of the following risk characteristics: premises; classification peculiarities; medical facilities; safety devices; employee selection, training, and supervision; management cooperation with the insurer; and management-safety organization. The overall schedule modification is subject to maximum and minimum values. The schedule rating plans contain minimum eligibility requirements based on premium at manual rates.

I. Other rating plans

In addition to the standard plans, some rating classes are subject to special rules. In the calculation of chemical and dyestuff rating classes, the applicable rates are tempered through a complicated averaging technique so that the more hazardous chemical classifications receive higher rates. Overall, no additional premium is produced through this procedure. Similarly, the rates for maritime coverage are determined through a combination of state act and federal act rates according to a pre-filed formula. Coal mine classes are subject to a different rate manual, rating rules, and experience rating plan. There are also merit rating plans, and loss deductible plans available in some jurisdictions. Michigan has a special plan for the wrecking of buildings, and Florida has a special plan applicable to contracting

CHAPTER 2

Current NCCI Rate-Related Procedures

classes. Other states have implemented an adjustment to the standard experience rating plan for contracting classifications called the Loss Ratio Adjustment Program (LRAP).

J. Policyholder dividend plans and practices

The NCCI does not file, recommend, or administer the dividend plans of any insurers.

K. Rate changes for policies in effect

The amount of workers compensation benefits in a state are determined by that state's legislature. It is customary for legislatures to modify the workers compensation benefit package from time to time. In addition, many state workers compensation statutes automatically adjust benefit levels in response to changes in an index, usually wages. Workers compensation benefit changes affect the benefits for all accidents on or after the effective date of the change.

The impact of these benefit changes are often not known at the time of policy inception, and are not included in the price. The workers compensation policy, however, automatically responds to pay the amount determined by the revised statute. Therefore, to respond to the changes in losses resulting from benefit changes, the workers compensation policy permits the insurer to revise the premium for the unexpired portion of the policy if approval is received by the regulator.

L. Retroactive rate changes

Occasionally, manual rates are not available to agents and/or insurers prior to the effective date of the rates. In that situation, the estimated premium for the policyholder is based on the prior rates. At audit, the final premium is calculated based on the approved rates. From the policyholder's perspective, this appears to

CHAPTER 2

Current NCCI Rate-Related Procedures

be a retroactive rate change.

M. Distribution of expense information to insurers

The NCCI publishes countrywide summaries of the Insurance Expense Exhibit, with loss, expense, and premium information shown by type of insurer (Stock, Mutual, Reciprocal, State Funds, Other). This information is compiled from the individual insurer submissions of the Insurance Expense Exhibits. In addition, the NCCI rate filings contain the expense allowances used in the determination of manual rates.

N. Employers liability increased limit percentages

The standard workers compensation policy includes employers liability coverage up to \$100,000 for bodily injury by accident, \$100,000 for bodily injury by disease, and a \$500,000 policy limit. The NCCI publishes a table of increased limit percentages to provide the premiums for higher limits, if so elected. The same table contains minimum premiums for the increased limits.

O. Loss constants

Loss constants apply in only a few states. Where applicable, one loss constant is used per state, corresponding to the classification with the highest loss constant. Loss constants are not subject to experience rating. Where applicable, the minimum premium includes the loss constant premium so a further addition is not necessary. Loss constants are not applicable if the premium in any state with loss constants is in excess of \$500.

P. Residual market classification relativities

In general, the NCCI files for the residual and voluntary market rates in the same filing. The residual voluntary market rates use the same classification relativities. In some states, the rates for the residual market are at a higher level than the voluntary

CHAPTER 2

Current NCCI Rate-Related Procedures

market rates. In other states, the same rates are used for both markets.

II. COMMITTEE ROLES

The NCCI has four committees directly affecting what is contained in a rate filing in administered-pricing jurisdictions.

A. Actuarial Committee

The Actuarial Committee is directly responsible for the ratemaking methodologies contained in the rate filing. Techniques for loss development, trending, experience periods, classification relativity calculations, credibility formulas, and so forth, are first approved by this committee prior to use in any state. These are the general techniques which become available to the NCCI staff for use in preparing the rate filing. The Actuarial Committee does not review the particular application of the methodologies chosen by the staff for use in any particular state in connection with a specific rate filing. Examples of Actuarial Committee decisions include:

Experience Period

Overall rate levels are determined on the basis of an unweighted average of the indications from the most recent calendar-accident year data and from the most recent completed policy year data.

Loss development methods

Currently available development methods are paid loss development, incurred loss development excluding insurer estimates for Incurred-But-Not-Reported losses (IBNR), and incurred loss development including insurer estimates for IBNR.

CHAPTER 2

Current NCCI Rate-Related Procedures

Regardless of which method is used, the unweighted average of the development emerging in the two most recent calendar years provides the basis for the development factors. NCCI staff independently reviews the specific conditions applicable in a particular state and recommends a method for use in a specific state for a specific filing. However, the Actuarial Committee does not review these recommendations prior to their use in a state filing.

Trending methods

The current procedure results from actuarial committee recommendations. NCCI staff may make specific adjustments, where appropriate, for a given state in connection with a specific filing. These staff decisions are not reviewed by the Actuarial Committee prior to their use.

Other decisions

The NCCI classification ratemaking procedures, including development methods, experience periods, national experience, and credibility, directly result from the decisions of the Actuarial Committee.

In addition, the Actuarial Committee reviews historical countrywide expense data and provides recommendations for the allowances to be used for production expenses; general expenses; miscellaneous taxes, licenses, and fees; and loss adjustment expenses. The committee also determines recommended Premium Discount Tables and expense constants. This review takes place annually and is used by NCCI staff in preparing rate filings in all administered-pricing states.

Other tasks performed by the Actuarial Committee are a review of the percentages for employers liability increased limits, which are then recommended for filing in all states when the Committee determines changes are appropriate, and implementation

CHAPTER 2

Current NCCI Rate-Related Procedures

of special programs. Examples of these special programs include rate differentials for residual markets and the elimination of premium discounts for the residual market.

B. Individual Risk Rating Committee

The Individual Risk Rating Committee reports to the Actuarial Committee. It is responsible for recommending the formulas used under the Experience Rating Plan, the Retrospective Rating Plan, schedule rating plans, merit rating plans, and other plans. The Actuarial Committee has final authority over the Individual Risk Rating Plan Committee.

C. Rates Committee

The Rates Committee reviews the specific rate indications and the specific methodology or methodologies recommended by the NCCI staff prior to their use in a particular state filing. This committee recommends the methodology and rate indication to the individual state's Classification and Rating (C&R) Committee for final approval.

D. Classification and Rating Committees

There are separate Classification and Rating (C&R) Committees for each state. They have final authority over the rate filings filed in their states, and they review all aspects of the rate indication, including the specific methodologies used. They consider the Rates Committee recommendations, but are not bound by them. The C&R Committees authorize the NCCI filings. They are also involved in the decisions whether to litigate or compromise in states where the original rate filing is disapproved.

In addition to their responsibilities concerning rates and rate filings, the C&R Committees also hear appeals by policyholders concerning the application of the

CHAPTER 2

Current NCCI Rate-Related Procedures

classifications and rates to their specific policy. They issue decisions regarding the specific classifications and rates which should be applied to the policies under appeal. The decisions of the C&R Committees on these issues can usually be appealed to the insurance department and/or the courts. The C&R Committees also have jurisdiction over individual classification definitions and new classifications.

III. DISTRIBUTION OF MATERIAL TO AGENTS/SALES REPRESENTATIVES

The NCCI provides a variety of materials to insurers; many of these are available to agents/sales representatives and the general public.

A. Rate and rule manuals

Three NCCI rate and rule manuals are available for agents/sales representatives and insurers.

Basic Manual

The Basic Manual contains the General Rules applicable to all states concerning the premium determination for workers compensation policies. It contains state pages listing exceptions to the General Rules and the rates applicable in a given state. Subscription service is available for updates.

Experience Rating Plan Manual

This manual contains the General Rules and formulas applicable to the Experience Rating Plan. It also contains state pages which list state exceptions and the current experience rating values (Expected Loss Rates, D Ratios, W and B values). Again, subscription service is available for updates.

CHAPTER 2

Current NCCI Rate-Related Procedures

Retrospective Rating Plan Manual

This manual contains the General Rules, formulas, tables, and endorsements applicable to the retrospective rating plan. State exception pages are also provided. Subscription service is available for updates.

B. Experience modification factors

NCCI sends experience modification calculations to the insurer of record 30 days prior to renewal. Additional copies of the experience modification factors are available, for a charge, with a letter of authorization. In addition, the NCCI provides experience modification factors over the phone to authorized requestors (principally agents/sales representatives).

C. Other products and services

The NCCI also provides a brochure containing the products and services it offers. They are available to insurers, as well as outside parties, including agents/sales representatives.

CHAPTER 2

Current NCCI Rate-Related Procedures

IV. RELATIONS TO REGULATORS

The NCCI submits filings to regulators and serves as their statistical agent.

A. NCCI rate filings

Rate filings in administered-pricing states are made with the insurance department and are subject to prior approval. The NCCI government, consumer, and industry affairs department is responsible for making and supporting the filings in each state.

B. Statistical agent

The NCCI is the statistical agent in administered-pricing states. A common Statistical Plan is filed and approved in most of the jurisdictions. Insurers are required to adhere to the Statistical Plan.

V. POLICYHOLDER SERVICES

NCCI provides the following policy services:

A. Policy review

Copies of individual policies are filed with the NCCI's field operations division, where the rates and payrolls are reviewed for compliance with the approved rates and classifications. These policy submissions set up a control procedure whereby the NCCI expects to receive Unit Statistical Reports in accordance with the Statistical Plan.

Unit Statistical Reports contain individual policyholder exposure, premium, and loss data. They are used in the calculations of classification relativities and experience modification factors.

CHAPTER 2

Current NCCI Rate-Related Procedures

B. Classification inspections

Another service provided by the NCCI field offices is individual on-site inspections to review the insurer's application of the correct classification code assignments. These inspections are performed as requested. In addition, inspections are performed on randomly selected risks.

C. Policyholder inquiries

Finally, the NCCI responds to individual policyholder requests concerning the rates and rating procedures it administers.

VI. DATA COLLECTION

The NCCI collects four distinct types of data:

A. Financial data calls

The NCCI bases the overall rate level changes on the data collected on financial data calls. These calls contain insurer aggregate loss and premium data.

Calendar year experience

Premiums and losses by state are on a calendar year basis. Premiums collected are standard earned premium at NCCI rates, standard earned premium at insurer rates (if deviations or schedule rating are used), and net earned premium (premium after the impact of premium discounts and retrospective rating adjustments). The losses are calendar year incurred losses.

CHAPTER 2

Current NCCI Rate-Related Procedures

Calendar-accident year experience

The premium information on this call is the same as that for the calendar year call, except that the history for up to the last 15 years is collected. The losses are split into indemnity and medical components, and paid losses, case reserves, bulk reserves, and IBNR reserves are collected for each accident year.

Policy year experience

The same three types of premium are collected; however, policy year premiums contain premiums for policies written during a one-year period. Ultimately, fifteen years of data will be collected. The losses are those that result from the policies issued in each year. The same indemnity/medical and paid/reserve breakdowns are provided as for the calendar-accident year call.

B. Statistical plan data

Data is continuously reported under the NCCI Statistical Plan as individual policy experience reaches the appropriate maturity. Payroll, premium, and loss information is provided on an individual policy basis. These data form the basis for the Experience Rating Plan modifications and the individual classification rate relativities.

C. Detailed claim information

This data system collects descriptive information on lost-time cases, and it is used to review the individual characteristics of losses in the jurisdictions where it is in place. It is not used directly in ratemaking, except to the extent it may provide information useful to the valuation of benefit changes.

CHAPTER 2

Current NCCI Rate-Related Procedures

D. Other data calls

These data calls are designed to provide supporting information for specific purposes. Information is sought for expense data, including the Insurance Expense Exhibit, state allocations of expenses, and special expense studies by size-of-risk. Information is collected on the impact of schedule rating adjustments, where it is used in the reconciliation of premiums on the other calls. There are also special calls requesting specific information in certain jurisdictions where these data are not available through other sources.

CHAPTER 3 NCCI Procedures in Loss Cost States

This chapter describes the services the NCCI and independent rating organizations provide to insurers in open competition and prior approval states which have already implemented loss costs. These services apply to the following states:

Connecticut
Georgia
Hawaii
Illinois
Indiana
Kentucky
Louisiana

Maryland
Michigan
Minnesota
New Mexico
Oregon
Rhode Island
South Carolina
Vermont

This chapter contains the following sections:

- I. RATE COMPONENTS AND RULES
- II. COMMITTEE ROLES
- III. DISTRIBUTION OF MATERIAL TO AGENTS/SALES REPRESENTATIVES
- IV. RELATIONS TO REGULATORS
- V. POLICYHOLDER SERVICES
- VI. DATA COLLECTION

There are independent rating organizations with jurisdiction in some of the states included in this chapter. The role of the independent rating organization and the relationship between the independent rating organization and the NCCI varies from state to state. Section I, *Rate Components and Rules*, discusses the components of loss costs developed by either the NCCI or independent rating organizations. Sections II through VI, discuss only NCCI procedures.

CHAPTER 3

NCCI Procedures in Loss Cost States

I. RATE COMPONENTS AND RULES

The discussion below relates to two types of loss cost states. The following major subdivisions apply:

1. Open competition states with advisory loss costs that exclude some or all expense and profit. The states listed here require the filing of advisory loss costs. The rate organization might also file advisory rates. Informational filings are made with the insurance departments containing these advisory loss costs.

Georgia
Illinois
Kentucky
Maryland

Michigan
Minnesota
Rhode Island¹
Vermont

¹Rhode Island is a competitive rating state for insurers with greater than 1% market shares, and a prior approval state for others. The NCCI files traditional rates for the insurers with less than 1% market shares.

CHAPTER 3

NCCI Procedures in Loss Cost States

2. Prior-approval states with loss costs. The loss costs filed by the NCCI in these states are subject to prior approval. In addition, individual insurers must file either a multiplier or full rates, also subject to prior approval.

Connecticut
Hawaii
Indiana¹

Louisiana
New Mexico
Oregon
South Carolina

¹Allows advisory rates.

In both sets of states, gross rates are filed for the residual market plans. The sections below discuss how loss cost filings consider the following: (A) Rates; (B) Expense constants; (C) Premium discounts; (D) Minimum premiums; (E) Anniversary rating date rule; (F) Experience rating plan; (G) Retrospective rating plans; (H) Schedule rating plans; (I) Other rating plans; (J) Policyholder dividend plans and practices; (K) Rate changes for policies in effect; (L) Retroactive rate changes; (M) Distribution of expense information to insurers; (N) Employers liability increased limit percentages; (O) Loss constants; (P) Residual market plan classification relativities; (Q) Other assessments; and (R) Classification relativities and definitions. We confine our discussions below to those states where some form of loss cost, either advisory or prior approval, is used.

A. Rates

The provisions included in the loss cost rates create the principal difference between the filings for the administered-pricing states (discussed in Chapter 2) and filings in the loss cost states (discussed in this chapter).

CHAPTER 3

NCCI Procedures in Loss Cost States

Provisions for losses

The rates filed in loss cost states consist of only the loss portion of the premium. States differ as to their treatment of the amount of actuarial adjustment permitted to historical reported losses in the published loss cost rates.

Loss Development

Loss development is always included in the loss costs. Minnesota, however, only allows development up to an eighth report. All other states allow development to an ultimate report. Minnesota, however, publishes pure premiums which include the differential impact of eighth-to-ultimate development as it impacts the more serious indemnity and medical losses. The Minnesota ratemaking report contains information concerning historical eighth-to-ultimate factors which could be used by insurers to convert the published loss costs to an ultimate basis.

Benefit level changes

These are included in all states. Oregon, however, does not permit the use of benefit adjustment factors representing the impact of changes in the maximum and minimum weekly benefits, which are indexed to that state's average weekly wage. Oregon believes that these benefit changes are reflected in the premium through payroll increases.

Trend

Trend is included in all states except for Michigan and Minnesota. Michigan excludes trend in its entirety, but Minnesota includes indemnity and medical trend relativities in the loss costs. The Minnesota ratemaking report provides information on observed trends and provides a method for insurers to include trend if they wish.

CHAPTER 3

NCCI Procedures in Loss Cost States

Provision for expenses

Provision for production expenses; general expenses; taxes, licenses, and fees; and premium-based assessments is excluded in loss cost filings.

Profit and contingencies

Provision for underwriting profit and contingencies is uniformly excluded in the loss cost filings.

Loss adjustment expenses

Loss adjustment expenses are included in a small majority of states (8 of 15 states). States excluding loss adjustment expenses are Georgia, Hawaii, Illinois, Kentucky, Louisiana, Maryland, and Oregon. Loss adjustment expenses are comprised of allocated and unallocated components. Allocated loss adjustment expenses are those specifically attributable to an identifiable claim, such as outside legal expenses. All loss adjustment expenses, both allocated and unallocated, are either included or excluded in the aggregate. We have not found a state which allows one type of loss adjustment expenses, but which excludes the other.

Loss-based assessments

States which include loss adjustment expenses generally also include loss-based assessments. Exceptions are Connecticut and South Carolina, which allow loss adjustment expenses, but exclude loss-based assessments.

Indiana, Rhode Island, and Vermont include loss adjustment expenses, but have no loss-based assessments to include. The states of Connecticut, Georgia, Hawaii, Illinois, Kentucky, Louisiana, Maryland, Oregon and South Carolina all have loss-based assessments but exclude them from the loss cost rates.

CHAPTER 3

NCCI Procedures in Loss Cost States

Disease elements

The disease elements in the loss cost states exclude the expenses and profit in the same manner as the rates for other classes.

B. Expense constants

Expense constants are excluded in all loss cost only filings. They are, however, included in states that allow both advisory rates and advisory loss costs. They are included in Rhode Island.

C. Premium discounts

Premium discounts are excluded in most loss cost only states. However, they are filed on an advisory basis in Hawaii and Rhode Island. They are included in states that allow both advisory rates and advisory loss costs.

D. Minimum premiums

Minimum premiums are included in the states where the NCCI or independent rate organization publishes both advisory rates and advisory loss costs, and they are also included in Rhode Island. In Oregon, the NCCI publishes only the loss cost portion of the minimum premium. Minimum premiums are not published in any other loss cost only states.

E. Anniversary rating date rule

This rule is applicable in all states listed above except Illinois.

CHAPTER 3

NCCI Procedures in Loss Cost States

F. Experience rating plan

The NCCI Experience Rating Plan is mandatory for all eligible policyholders in all of the above states except Michigan. Insurers must file their own plans in Michigan.

G. Retrospective rating plans

States differ in their treatment of NCCI retrospective rating options. Implicit in options 1 through 4 are the standard expense allowances and premium discount schedules. The NCCI includes references to plans 1 through 4 in all states that allow advisory rates as well as advisory loss costs. The Rhode Island filing also references plans 1 through 4. The other loss cost only states do not include references for plans one through four.

Option 5 is more complicated in that some aspects of this plan include expense elements whereas other aspects do not. In advisory-rate states, all values pertaining to option 5 are supported. The practice in loss cost states, however, is to eliminate all reference to the items in option 5 which relate to expenses or which are impacted by expenses. Specifically, the following references are eliminated:

- Expected Loss Ratios - These depend upon the final expense allowances in the manual rates.
- Table of Expense Ratios - These depend on the actual expense needs of retrospectively-rated policies.
- Loss Conversion Factor - These depend upon the expense needs of retrospectively-rated policies.
- Tax Multipliers - These depend upon the specific tax provisions applicable in a state.
- Retrospective Development Factors - These depend on the expense allowances included in the manual rates.

CHAPTER 3

NCCI Procedures in Loss Cost States

Items that are preserved in option 5 for the loss cost states include:

- **Table of Expected Loss Ranges** - This is maintained in some states, but reference to it appears to be eliminated in others. This table indicates which column of the Table of Insurance Charges is applicable to risks of a given size, when size is measured in terms of expected losses.
- **Table of Insurance Charges** - This table is the key to determining the amount to charge for the minimum and maximum premiums agreed to under the retrospective rating option. The net insurance charge is expressed as a percentage of expected losses, and consequently does not include expense provisions.
- **Excess Loss Factors** - This table determines the amount of losses expected in excess of specific loss limitations. The tables in administered-pricing states are expressed as percentages of standard premium which presume the standard expense loadings. A modification to these tables is made in loss cost states to express the losses expected in excess of specific loss limitations as percentages of the loss cost portion of the premium, rather than as a percentage of standard premium. This modification eliminates the impact of expenses in these factors.

H. Schedule rating plans

Of the states considered in this chapter, the rating organizations file a schedule rating plan only in Indiana, New Mexico, Rhode Island, and South Carolina.

I. Other rating plans

In advisory-rate states, the special rating plans continue as they have in the administered-pricing states. For the loss cost only states, these rating plans are adapted to the loss cost environment without difficulty.

CHAPTER 3

NCCI Procedures in Loss Cost States

J. Policyholder dividend plans and practices

The rating organizations do not file, recommend, or administer the dividend plans of any insurers.

K. Rate changes for policies in effect

The NCCI files for an adjustment for outstanding policies in situations where a benefit change has a significant impact on benefit costs in the same manner as in the administered-pricing states discussed in Chapter 2.

L. Retroactive rate changes

We did not find an example of where this occurred in an advisory-rate or loss cost state.

M. Distribution of expense information to insurers

The NCCI publishes countrywide tabulations of historical expense data contained in insurer Insurance Expense Exhibits. Specific expense allowances are shown in NCCI filings in states which allow advisory rates as well as advisory loss costs. There are no voluntary market expense allowances distributed to insurers for the loss cost only states.

N. Employers liability increased limit percentages

These are applied in the traditional manner.

CHAPTER 3

NCCI Procedures in Loss Cost States

O. Loss constants

Loss constants did not apply in any state reviewed in this chapter.

P. Residual market plan classification relativities

Generally, residual market filings are made at the same time as the voluntary market filings, but are filed separately. The residual market maintain the same classification relativities as the voluntary market in the loss cost states.

Q. Other assessments

A few states have assessments which are charged directly to policyholders and are not a part of the workers compensation premium. Examples of states with these assessments are Kentucky and Oregon.

R. Classification relativities and definitions

Some states require adherence to the rating organizations' classification definitions, while others allow individual insurer definitions. Where individual definitions are allowed, data is converted back to NCCI definitions. Of the prior approval states, Oregon allows insurers to subdivide the rating organization's classifications.

Independent insurer classification relativities is a related issue. Of the prior approval states, New Mexico and Oregon allow it. It has not been tested in South Carolina and Hawaii. Connecticut and Louisiana do not allow independent classification relativities.

CHAPTER 3

NCCI Procedures in Loss Cost States

II. COMMITTEE ROLES

The NCCI committees, active in the administered-pricing states, have a restricted role in the loss cost and competitive rating states identified in this chapter.

A. Actuarial Committee and Individual Risk Rating Committee

The activities of the Actuarial Committee and the Individual Risk Rating Committee are the least affected because they operate on a general basis, non-specific to a particular state or rate filing. The basic procedures, tools, and techniques used in the loss cost states are the same as those for the other states. However, these committees do not have any authority concerning a specific state filing.

B. Rates Committee

The Rates Committee does not issue any recommendations concerning the rate filings in the loss cost and competitive rating states. The NCCI staff makes all decisions concerning the specific elements to include, the final methodologies chosen, and the timing and amounts of rate filings.

C. Classification and Rating Committees

Each Classification and Rating Committee relinquishes its authority over voluntary loss costs and residual market rates in each of these states. The NCCI staff is fully responsible for the contents of the rate filings. The Classification and Rating Committees, however, still perform their functions concerning the application of the classification plan to particular policyholders.

CHAPTER 3

NCCI Procedures in Loss Cost States

III. DISTRIBUTION OF MATERIAL TO AGENTS/SALES REPRESENTATIVES

Instead of manual rates, the Basic Manual contains advisory rates or loss costs. In loss cost states, retrospective rating plans 1 through 4 are generally excluded. The same Basic Manual, Experience Rating Manual, Retrospective Rating Manual, and products and services are available in most states. The NCCI does not publish advisory loss costs for Minnesota's voluntary market in the Basic Manual. However, the Minnesota Workers Compensation Insurance Association, Inc. does publish advisory loss costs in its Minnesota Ratemaking Report. This publication is available to agents/sales representatives, insurers, and other interested parties.

Experience modification factors are calculated and promulgated in the same manner as in the administered-pricing states. An exception exists in Michigan, which does not use uniform manuals or a uniform experience rating plan. Consequently, no manual pages or experience modification factors are issued for that state.

IV. RELATIONS TO REGULATORS

The NCCI role with regulators includes the following:

A. NCCI rate/loss cost filings

In the loss cost and competitive rating states, rate filings are made with state insurance departments. The loss costs or advisory rates are informational filings in the competitive rating states, and are subject to prior approval in prior-approval states. The NCCI's government, consumer, and industry affairs department is responsible for making and supporting the filings in each of these states in the same manner as in the administered-pricing states, but without guidance from insurer committees.

CHAPTER 3

NCCI Procedures in Loss Cost States

B. Individual insurer rate filings

In some states, particularly the advisory-rate states, individual insurers can reference the NCCI filing and adopt it as their own. Alternately, they can reference the loss cost component in the states with advisory loss costs, but must file for the other elements constituting final rates. Frequently, a multiplier from the loss costs is all that need be filed. In the prior approval states, a similar referencing can take place. Usually, if approved, the NCCI's loss costs are the mandatory starting point for individual insurer rates. Adjustments to the level of loss costs, for factors relating to losses as well as expenses are frequently permissible.

C. Statistical agent

The NCCI is the statistical agent in the advisory-rate and loss cost states. A Statistical Plan is filed and approved in most of the jurisdictions. Insurers are required to adhere to the Statistical Plan. Where insurers are free to use subclassifications or other adjustments to the NCCI's Statistical Plan, the insurers must convert data back to the NCCI's Statistical Plan for statistical reporting purposes.

V. POLICYHOLDER SERVICES

NCCI provides the following policyholder services:

A. Policy review

Copies of individual policies are filed with the NCCI's field operations division. The rates are not reviewed, but the payrolls and classifications are. These policy submissions form the basis for the control procedure governing the statistical reporting and experience rating requirements expected to emerge in the future as a result of the policy reviewed.

CHAPTER 3

NCCI Procedures in Loss Cost States

B. Classification inspections

Classification inspections continue in the usual manner for the open competition states as well as for the administered-pricing states. As a result of the inspection, the NCCI instructs the insurer on the appropriate NCCI classifications for the risk.

VI. DATA COLLECTION

Of the data collected in NCCI calls, the financial data and the special calls are impacted the most by loss costs. Statistical plan reporting is impacted in a minor way, and the detailed claim call not at all.

A. Financial data calls

The loss information on the three financial data calls, i.e., calendar year call, policy year call, and calendar-accident year call, are no different in the loss cost or advisory-rate states. The reporting of premiums, however, is substantially different. The loss cost and advisory rate states use the concept of a Designated Statistical Reporting (DSR) level for the reporting of the premiums in these states. In the states which allow the NCCI to publish both rates and loss costs, the DSR is usually at the level of the advisory rates published during the applicable time periods. In states that allow only loss costs, the DSR is usually at the level of the NCCI's published loss costs.

The use of advisory rates or loss costs, therefore introduces a complication to the reporting process. Insurers must report amounts they would have charged had they used either the NCCI's published advisory rates or published loss costs. The NCCI requests the Standard Earned Premiums at the DSR level, the Standard Earned Premiums at insurer level (i.e., the actual charged rates), and Net Earned Premiums. The Net Earned Premiums are at insurer level and include the impact of premium discounts and retrospective rating adjustments.

CHAPTER 3

NCCI Procedures in Loss Cost States

This process appears to be working satisfactorily at this time. However, for most insurers in most states the difference between DSR premium and standard premium is a uniform multiplier. As individual insurers deviate by classification from NCCI loss costs, it becomes more difficult for the insurer to maintain DSR premium information and it becomes more difficult for the NCCI to verify the accuracy of the insurer data.

B. Statistical plan data

The statistical plan reporting continues in exactly the same manner in the advisory-rate and loss cost states. The rates and premium reported under this plan are to be the actual rates charged for the policy. The reporting of losses is unaffected.

C. Detailed claim information

Since the detailed claim call collects only loss and claim information, it is unaffected and functions normally in these states.

D. Other data calls

The other data calls are adapted to DSR level concept where appropriate.

CHAPTER 4

Loss Costs as Applied by ISO

This chapter contains the following sections:

- I. ISO APPROACH
- II. STATE REGULATORY CHANGES
- III. CALIFORNIA RATING LAWS
- IV. MATERIALS SUPPLIED BY ISO
- V. MAJOR DIFFERENCES BETWEEN ISO AND NCCI

I. ISO APPROACH

Some important points to consider in a discussion of the ISO implementation of loss costs are:

- Loss costs include loss development, trend factors, and all loss adjustment expenses.
- The change to loss costs is being made gradually, state by state, at state rate revision anniversary dates.
- Rules and rating factors are generally not affected by the change to loss costs.
- Individual risk rating plans will be modified to "key off" of loss costs rather than premiums. This will allow the same plan to apply to insurers with different expense loadings.
- Retrospective rating plans will not be changed. They have been designed to reflect insurers' own expense provisions, rather than the ISO provisions underlying manual rates. Therefore, ISO believes that any modification to the plans is not necessary.

CHAPTER 4

Loss Costs as Applied by ISO

- As of October 1990, approximately 35 states have adopted loss cost procedures. ISO did not expect adoption of loss cost procedures in Texas and Puerto Rico. The status of procedures for the remaining states is pending.
- For automobile insurance, ISO has responsibility for voluntary rates only. ISO is not responsible for residual market rates, except in that it serves as statistical agent for AIPSO. Residual market rates are still determined on a gross basis by AIPSO.

II. STATE REGULATORY CHANGES

The NAIC has two model rating laws: a competitive rating law and a prior-approval law. The competitive rating law has not been changed, since it already refers to ISO loss costs. The prior approval law, which previously required that advisory organization rates be filed for prior-approval, has been modified to require that advisory organization loss costs be filed for prior approval.

Under the NAIC-suggested prior-approval procedure, ISO obtains prior approval of loss cost documents. Insurers are required to complete and file for prior approval a form to reference the ISO document, with an expense and profit load and possibly a loss provision modification.

A standard form has been prepared by the NAIC enabling an insurer to reference files from the ISO rate circular, adding expense and profit provisions, and perhaps loss deviations, in a uniform format. The form requires support for the provisions proposed by the insurer.

In states with use and file rating laws, the ISO loss cost circulars and insurer forms will also be filed and subject to evaluation by the insurance department after the rates have been put into effect.

We have not found any states considering fundamental changes in their rating laws, e.g., changing from use and file to prior approval, as a result of the ISO loss cost change. Instead, states are only modifying their regulations where necessary to accept loss costs instead of rates.

CHAPTER 4

Loss Costs as Applied by ISO

Massachusetts, Texas, and North Carolina have statutory rating organizations for some lines of insurance. In these states, no action has been taken to adopt loss cost procedures for statutory line of insurance.

III. CALIFORNIA RATING LAWS

The California system for Proposition 103 lines of insurance (i.e., excluding workers compensation) is unlike the systems in other states. The ISO loss cost approach is not used in California. Instead, insurers individually file a detailed series of forms in which losses are trended, loaded for expenses and profit, and so forth. All computations are done by the insurers on the forms, with all necessary judgements made by the insurers.

ISO is permitted to maintain a personal automobile data bank which is accessible, for a fee, to insurers. In other respects, ISO continues to operate as a statistical agent in California.

Residual market rates are computed by the California Assigned Risk Pool Association. These rates are uniform for all insurers, and are set by prior approval of the department.

IV. MATERIALS SUPPLIED BY ISO

The standard form developed by the NAIC is structured so that an insurer can have it apply only to the most current revision, or to future revisions until the form is resubmitted.

For commercial lines, ISO will distribute loss cost manual pages to insurers and agents/sales representatives on their mailing list. Manual holders will determine gross rates either by obtaining factors or gross rate pages from insurers. They also may obtain the gross rate information from computer servicing organizations.

For personal lines, ISO will produce a manual containing rules only. Loss costs will be distributed by circular to insurers. No manual pages will be distributed by ISO.

CHAPTER 4

Loss Costs as Applied by ISO

ISO publishes other advisory circulars containing information which may be used by insurers to support their pricing actions, for example, expense data by line and by size-of-risk, loss compilations, trend and loss development circulars, and premium comparisons (for personal lines only, and not in all states).

As stated above, ISO is changing its individual risk rating plans to a loss cost basis. To help insurers adapt to this change, they are distributing explanatory material regarding the change and also are distributing material explaining how an insurer might convert the ISO loss cost plan to its own premium plan.

ISO has prepared educational materials to assist insurers and agents/sales representatives with the transition to loss costs. In addition, they participated in a video teleconference with the Society of Chartered Property and Casualty Underwriters (CPCU) to disseminate loss cost information.

ISO has shifted all responsibility for decisions on actuarial methodology and judgment to the ISO staff. Many of these decisions were formerly made by insurer committees. ISO still has insurer committees, but they act strictly in an advisory capacity.

V. MAJOR DIFFERENCES BETWEEN ISO AND NCCI

The ISO statistical data base is not significantly changing as a result of the implementation of loss costs. However, some major aspects of the ISO data base are different from those of the NCCI workers compensation data base.

The ISO data base is used only for ratemaking. This is unlike the NCCI data base, which is used for experience rating as well as ratemaking. Because of the experience rating requirement, the NCCI data base is a policy data base, where premiums and losses on individual policies can be identified. The ISO data base, however, is actually comprised of a premium/exposure data base and a loss data base, where the two are processed separately. It is thus not possible to match up premiums and losses on individual policies from the ISO data base.

The ISO rules are also more flexible than the NCCI rules in several respects, and this is reflected in the larger number of options in the ISO Statistical Plan. For example,

CHAPTER 4

Loss Costs as Applied by ISO

ISO experience rating plans are optional, while NCCI plans are mandatory. Also, ISO has schedule rating plans permitting premium credits and debits based upon subjective underwriting criteria in all states, while the NCCI does so only in approximately a dozen states.

There is also much less uniformity of policy forms and coverages underlying the data in the ISO data base than is the case for workers compensation. Many insurers have their own special package program or unique coverages and report the experience for these packages or coverages to ISO, but it is specially coded and used in a limited fashion for ratemaking.

ISO has "A-rated classes," broadly defined classes (e.g. metal products manufacturing) where ISO believes that the average loss per exposure for the class is not indicative of the loss potential for any particular risk within the class. For this reason, ISO does not determine manual rates for A-rated classes. The NCCI, on the other hand, has just a limited number of A-rated classes.

Not all ISO data for standard coverages or packages is used for commercial lines ratemaking; several large classes such as composite-rated risks, large A-rated risks, and loss-rated risks are excluded. This data corresponds to larger corporate risks, where it is believed that premiums are not based on ISO manual rates. This varies from workers compensation, since, workers compensation rates are computed based on experience from all risks.

ISO has a three-tiered statistical plan, i.e., a full plan, an intermediate plan, and a mini-plan. The smallest insurers qualify for the mini-plan, while the largest must use the full plan. The mini-plan data is usually excluded from ratemaking calculations for all commercial lines. The intermediate plan data is used for overall rate level calculations, but not for increased limits factor calculations and is used in a limited fashion for other relativity calculations. The NCCI only has one statistical plan for all insurers.

Some insurers have received permission from ISO to submit data in limited detail. Exposure units are typically not provided in these cases, so the data cannot be used for ratemaking.

Package policies represent a fundamental difference between ISO and the NCCI, in

CHAPTER 4

Loss Costs as Applied by ISO

that ISO has package policies and the NCCI does not. For commercial lines, ISO segregates monoline and package data. Furthermore, not all package policy data is included in the ISO data base. Data from the ISO SMP Package Program and certain insurer package programs are included in the ISO ratemaking data base, but other insurer package policies are not. ISO makes the decision whether or not to include an insurer's data.

Conversely, the workers compensation data base currently includes data for all risks and is not affected by package variations. Complete recording is required of all insurers reporting to the NCCI.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

This chapter describes a manner in which loss costs could be implemented for workers compensation in NCCI administered-pricing states with a minimum of disruption to the current system. This plan adopts the features common to existing workers compensation loss cost states on issues specific to workers compensation, and it uses concepts from the ISO loss cost procedures in areas where national issues are involved. The system is referred to as the Typical loss cost system. Many variations to this typical system are possible, and some of these are also discussed.

In this chapter we will discuss assumptions in the following areas:

- I. CONTENTS OF NCCI LOSS COST FILINGS
- II. EXPERIENCE RATING PLANS
- III. INSURER FILINGS
- IV. CLASSIFICATION RATING
- V. RETROSPECTIVE RATING
- VI. SCHEDULE RATING
- VII. RELATIONSHIP BETWEEN NCCI AND INSURER COMMITTEES
- VIII. INFORMATION SUPPLIED TO INSURERS
- IX. RESIDUAL MARKET RATES AND RATING VALUES
- X. POLICY FORMS
- XI. OTHER MANUAL RULES
- XII. DISTRIBUTION OF INFORMATION TO AGENTS/SALES REPRESENTATIVES

CHAPTER 5

A Typical Workers Compensation Loss Cost System

XIII. AVAILABILITY OF NCCI DATA

XIV. TRANSITION PROVISIONS

I. CONTENTS OF NCCI LOSS COST FILINGS

The NCCI would produce loss cost filings in which loss costs are based on historical loss experience modified by loss development, adjustments to current benefit level, and trend. The following additional adjustments would also be included in the loss costs:

- a. Residual market subsidies to be paid by voluntary market policyholders
- b. Loss-based assessments
- c. Loss adjustment expenses, both allocated and unallocated
- d. Disease loss components

As part of the filing, the NCCI would produce loss costs by rate classification. Classification rates would reflect all relevant actuarial procedures, including adjustment for the off-balance in the Experience Rating Plan.

NCCI would also evaluate benefit changes and file in-force policy loss cost adjustment tables.

Currently, the NCCI loss costs include these elements in most loss cost states. A notable exception is Michigan, which does not include trend. Another exception is Minnesota, where the Minnesota Workers Compensation Insurers Association, Inc. (MWCIA) loss costs reflect special treatment of trend and loss development. The

CHAPTER 5

A Typical Workers Compensation Loss Cost System

treatment of loss-based assessments is variable among loss cost states, some include them, but most states exclude them.

These elements are discussed below.

A. Loss development and trend

All states for workers compensation and all states except California for ISO lines have included loss development in the loss costs produced by the rating organization.

One partial exception is Minnesota workers compensation, in which MWCIA loss costs are developed to 8th report, and companies are supplied with information that includes several methodologies with which to calculate development factors from 8th report to ultimate. The Minnesota exception may be viewed as a response to its unique circumstances. Minnesota law provides escalating benefits which have a tendency to increase the loss development "tail" beyond the 8th report. Minnesota also has a mandatory reinsurance pool that covers large claims. This shortens the tail on net of reinsurance data.

All states except Michigan and Minnesota for workers compensation, and all states except California for ISO lines, include trend in the loss costs produced by the rating organization.

While it is true that functioning markets exist in states that have followed alternate paths, to exclude trend and loss development from loss costs for workers compensation would be a major departure from the existing programs. At a minimum, it is likely that if trend or loss development were excluded in whole or in part from the loss costs, additional data must be made available to insurers, and educational efforts would have to be augmented.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

B. Loss adjustment expense

The treatment of loss adjustment expense varies widely among loss cost states in the workers compensation system. Loss adjustment expense is included in the ISO loss costs, except in California.

Insurers divide loss adjustment expense into two categories. The first, allocated loss adjustment expense, (ALAE) refers to claim handling expenses assigned to a specific claim file, for example, attorney fees for a specific case. The second, unallocated loss adjustment expense, (ULAE) refers to claims handling expenses that are not assigned to particular files. These could include the cost of salaries for a claim department.

For liability coverages, allocated loss adjustment expense is defined by ISO to include only the legal defense provided to the policyholder under the terms of the contract. This does not depend on the manner in which the insurer handles claims. ALAE can be included in the overall loss costs and distributed in the ratemaking system to states, territories, and classifications. ULAE by its nature, is not directly chargeable to states, territories, and classification.

For workers compensation, there has not previously been a precise definition of allocated loss adjustment expense for NCCI Statistical Plan purposes. Since the relative proportion of expenses between ALAE and ULAE depends on the extent to which an insurer uses salaried claim personnel or outside claim personnel, the expense distribution varies among insurers. Including only allocated loss adjustment expenses for workers compensation is thus not feasible because insurers may have far different distributions of allocated versus unallocated when compared to the industry, and the resulting loss costs would not properly represent average costs.

Therefore, we propose that all loss adjustment expense be included in the typical system. The alternative is to include no loss adjustment expense. There have been some NCCI attempts to obtain better allocated loss adjustment expense data in the rating system, so it may be premature to eliminate all loss adjustment expense from a nationwide loss cost system.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

Even when loss adjustment expense is included in loss costs, insurers can readily use different loss expense provisions by adjusting their loading factors.

C. Assessments

Workers compensation is unlike most other types of insurance with respect to the range of assessment programs. For example, workers compensation may be subject to assessments for (1) second injury funds, (2) workers compensation board expenses, (3) supplemental benefit funds, (4) reinsurance funds, and so on. The magnitude of the assessments varies widely from state to state, and the assessment base also varies from state to state and program to program. For example, some assessments are based on premium, some on premium after several adjustments, some on paid indemnity losses, and some on total paid losses; some are charged directly to policyholders like a sales tax, rather than included in premiums.

Most of the workers compensation states permit the advisory organization to include loss-based assessments in the loss rate. If loss costs do not include loss-based assessments, it becomes particularly important that the NCCI summarize and report to insurers on the details of assessment provisions.

D. Residual market subsidies

Voluntary loss costs would contain provision for residual market subsidies to be paid by voluntary market policyholders. There are three possibilities. First, if the voluntary and residual markets experience is combined to determine a uniform level of loss costs, then the voluntary loss costs will contain a subsidy, provided the assigned risk experience is worse than the voluntary market. Second, if some but not all of the generally worse than average experience is reflected in the assigned risk rates, then the subsidy will be lower, but will still be positive. Finally, if the assigned risk rates reflect all of the experience differential, then there is no voluntary market subsidy.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

II. EXPERIENCE RATING PLANS

In the typical system there would be a single Experience Rating Plan applied to all policyholders. The rating values underlying the plan would be determined by NCCI as part of the loss cost filing. Therefore, as under the current administered-pricing procedure, the experience modification factor for policyholders would be the same no matter which insurer offers coverage. The modification factors would continue to be calculated by the NCCI or the appropriate rating (advisory) organization. Therefore, the NCCI would continue to collect the policyholder data that underlies the experience modification calculations.

These decisions are discussed below.

A. Experience rating in workers compensation loss cost states

In workers compensation loss cost states, the experience rating plans are generally mandatory. Only Michigan permits variations in the plan among insurance companies.

B. Goals of an experience rating plan

The use of a mandatory common experience rating plan is intended to produce more equity among policyholders than insurer-designed plans or the voluntary plans used in other lines of insurance. If mandatory experience rating were eliminated, the experience rating process is likely to be more market-driven and less cost-driven.

The use of a common experience rating plan, centrally administered and applied to all policyholders, has been viewed as important because it is intended to encourage policyholder loss prevention in ways which may not be achieved through individual insurer action. The use of a common plan can reduce policyholder confusion and permit policyholders to compare their experience to that of other similarly-classified policyholders.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

C. Other issues

If a common experience rating plan is to be used, the NCCI needs to continue collecting individual policyholder data. If a common, centrally-administered plan is not to be used, the NCCI's data collection goals could change. The NCCI could then collect data for exposures and claims, but need not retain the ability to match individual policyholder exposures and losses. This kind of data base is simpler to maintain than the current NCCI database.

Our typical system has a common experience rating plan which applies to both voluntary and residual markets. The rating parameters will be based on the combined experience of the voluntary and residual markets.

There is potentially some logical inconsistency in simply applying a uniform set of experience rating values for companies charging different rate levels. For example, suppose one insurer charges 20% more than another insurer because its loss costs per unit payroll are 20% higher. Use of a common experience rating plan could double-count the adverse experience, since the experience rating parameters are used to measure how much better or worse an individual risk is compared to an average risk. The situation can be handled satisfactorily by the proper selection of the insurer loss cost multiplier. For example, if Insurer A's risks are 20% "worse" than average, then the loss cost differential must be chosen so that the loss cost differential, in combination with the average experience modification, produces the proper amount of premium differential for Insurer A.

III. INSURER FILINGS

Insurers would file a loading factor with the insurance department. This loading factor would adjust loss costs for insurance insurer expenses, profit, and possible differences in expected loss cost levels.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

In addition, insurance companies would file their own premium discount plans, expense constant programs, minimum premiums, and schedule rating, as appropriate.

A form should be developed to assist the insurers with the calculations necessary to derive the multiplier. Workers compensation has an expense structure, which includes expense constants and premium discounts. This is more complex than the expense structures in filings for other commercial lines of insurance. Furthermore, workers compensation is also more commonly subject to assessments than other lines of insurance. The filing form should accommodate these elements of the workers compensation expense structure.

It would also be beneficial to regulators and insurers if NCCI provides some summary expense information. This is discussed in item VIII, below.

The rate multiplier filed by an insurer would remain in effect until it is revised by the insurer or disapproved by the insurance department. That is, if the NCCI files a new set of loss costs, the insurer would automatically adopt the new loss costs with its current rate multiplier unless it files to do otherwise. This includes changes in loss costs caused by changes in benefit levels (i.e., law amendment adjustments). Insurers would be permitted to automatically adopt NCCI in-force loss cost adjustment tables when necessitated by benefit changes and approved by the insurance department.

In cases we studied, the loadings sometimes remained in effect until changed. Of seven prior-approval states three allow loadings to continue, and four do not. The alternative procedure would require that insurers constantly reevaluate their loading and may lead to increased competition. On the other hand, insurance departments would need to process far more filings than they would have to process in the typical system.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

IV. CLASSIFICATION RATING

In the typical system, we assume insurers have limited freedom to establish alternative classification relativities and new classification definitions, so long as provisions are made to redefine the experience in standard classifications for ratemaking purposes. For each state, the degree of permitted independence would be the same in loss cost states as it is in the current system. This approach should be able to maintain the existing level of integrity of data for experience rating, overall loss cost calculations, and classification relativities.

Increasing insurer independence is feasible, but it increases the risk to the accuracy of experience rating, overall loss cost calculations, and classification relativities. Diligence by NCCI and insurers could control those risks. However, particularly during the transition to loss costs, the effort required for that increased diligence may not be available.

The risks to the various elements of the NCCI process were discussed in Chapter 1.

V. RETROSPECTIVE RATING

NCCI would continue to provide support for the loss elements of retrospective rating. Options 1 through 4, which rely on tables that include expense elements, would no longer be available. In any event, the NCCI intends to eliminate these options for other reasons, including the fact that they are not frequently used.

Insurers will have to determine their own expense tables for use in option 5. This should not be a significant problem, because these plans are generally used by more sophisticated insurers.

Furthermore, the NCCI is currently responsible for reviewing insurer retrospective rating plan calculations. That service would be discontinued as a standard practice, but the NCCI could provide the service if requested by an insurer. Again, since retrospective rating plans are generally used by more sophisticated insurers, we do

CHAPTER 5

A Typical Workers Compensation Loss Cost System

not expect that the review service would be frequently used. In order for the NCCI to review an insurers retrospective rating plan calculation, the insurer would need to provide its expense provisions to the NCCI.

VI. SCHEDULE RATING

If schedule rating plans are permitted, the NCCI would be allowed to file advisory plans. Any insurer wishing to file an alternative schedule rating plan would be permitted to do so.

VII. RELATIONSHIP BETWEEN NCCI AND INSURER COMMITTEES

NCCI staff would make all decisions regarding loss cost filings. This would include decisions regarding loss development, trend, the effect of changes in benefit levels, classification relativity capping procedures, and others. If the loss cost filing is subject to approval by a state insurance department, NCCI staff would be responsible for negotiations required in achieving a resolution. These issues would not be referred to committees of insurers.

The NCCI Actuarial Committee could continue to provide advice, but would not be permitted to require staff to adopt procedures generally or in any specific states.

The state Classification and Rating Committee would no longer make state specific recommendations regarding loss cost filings, but they would continue to have a role as referee in classification disagreements between policyholders and insurers.

The Classification and Rating Committee may still advise NCCI staff on establishing new classification codes and/or refining existing class code definitions. However, the specific loss costs to be implemented for individual new classifications would be decisions of the NCCI staff.

The removal of insurer personnel from a decision-making role in the loss cost preparation and filing process is common to all the systems we studied.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

We believe that the use of Classification and Rating Committees (C&R) to referee classification disputes is reasonable given the use of a common classification system. Moreover, this reduces the burden upon insurance departments, which would otherwise need to serve as the first level referee for those classification disputes. This is not an issue for ISO lines where classifications are not necessarily uniform across companies. It should be noted that if common classifications are not required then the classification role of the C&R Committees might no longer be necessary.

VIII. INFORMATION SUPPLIED TO INSURERS

NCCI should supply a broad spectrum of materials to insurers to assist them in making independent decisions about their pricing behavior.

Material to be supplied to insurers should include the following categories:

A. Information relating to NCCI's loss cost calculations

This would include such material as alternative approaches for loss development and trend, and information on judgmental decisions such as classification relativity capping. This is the type of information provided in detail form by the Minnesota Workers Compensation Insurers Association and in summary form in NCCI rate adequacy studies.

Increasing the information supplied to insurers seems valuable in a competitive environment. All states we studied permit the advisory organization to publish as much loss cost (as defined in the state) information as it considers appropriate. The NCCI should be permitted and encouraged to maximize the information it publishes so that insurers can knowledgeably evaluate the appropriateness of industry-wide loss cost provisions in relation to their manner of operation, their views of trend, loss development, and so forth.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

B. Premium tax and assessment information

This would include information on premium tax levels in the state, assessment levels in the state, and how those assessments are handled in the loss costs.

C. Expense information

The NCCI would summarize insurer expense ratio data in a form where (1) expenses are adjusted to eliminate the impact of residual market servicing insurer fees; (2) expenses are shown on a uniform size-of-risk basis, and (3) premiums are put on a common level, for example, the DSR level which is the loss cost level in loss cost states. This information should be provided for a number of categories of insurers including stock insurers, non-stock insurers, small insurers, large insurers, and regional insurers.

Commission variations by size-of-risk would not be addressed by the NCCI.

If multi-company studies of expense by size-of-risk are not available to insurers and regulators, then it is likely that insurer operating expense discounts will become more market-driven rather than cost-driven. Multi-company information on expense by size-of-risk is desirable for developing residual market rates. In this typical system, the NCCI would continue to conduct expense studies by size-of-risk and make that information available to insurers and regulators.

The publication of expense information is potentially subject to more contention. ISO publishes expense data. In workers compensation to date, the expense issue has not been significant, since NCCI generally uses countrywide expense provisions, which would be readily available until a nationwide loss cost system is established. Even after a loss cost system operates nationally, some expense data would be available through the residual market rate filings.

The issue of expenses for ratemaking is more complex in workers compensation than for other lines of insurance due to the regular use of such items as premium discount plans and expense constants. If the NCCI is not permitted to publish any expense information, there is a risk of unnecessary confusion.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

D. Instructions on how to calculate loss cost multipliers

This should include theoretical discussion as to where individual insurers might obtain expense information for their own use.

E. Premium comparisons

ISO publishes premium comparison information for a number of its lines of insurance. It may be desirable for NCCI, or some other party, to do this for workers compensation.

F. Individual insurer loss compilations

Both the NCCI and ISO make available to individual insurers compilations of their own loss data. To increase competition, regulators might encourage insurers, especially larger insurers, to rely more on their own loss data.

IX. RESIDUAL MARKET RATES AND RATING VALUES

The NCCI would continue to develop gross rates and rating values for the residual market. Insurers would be provided with sufficient information to analyze the voluntary and residual market experience separately.

Overall rate level

A residual market loading in voluntary prices becomes more visible in a loss cost environment. Regulators will need to establish a policy on the extent to which residual market rates are self-supporting and the extent to which those rates are supported by subsidies from voluntary rates. The typical system assumes that the residual market subsidy is included in voluntary loss costs.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

Classification rates and rating values

Since policyholders move between the voluntary and residual markets, and since classification data may be sparse in either market separately, it seems reasonable to combine the experience for calculating classification relativities.

The interaction of classification relativities and experience rating plan values discussed earlier also applies to ratemaking for residual markets. The relative distribution of residual market policies and voluntary policies by classification can also affect this calculation. Technical aspects of this issue require future NCCI analysis; in the meantime, the use of common rating values is a reasonable approach.

X. POLICY FORMS

Insurers would be allowed to continue to participate in the design and filing of policy forms. Uniformity of coverage for workers compensation is generally required because of the statutory nature of the benefit.

XI. OTHER MANUAL RULES

The anniversary rating date rule would be preserved under the typical system. This would reduce the strain on the system that calculates experience modifications, compared to alternate scenarios that could eliminate this rule.

The anniversary rating date rule has two components:

- a. NCCI prepares experience rating modifications once a year at a date which approximates the policyholder renewal date.

CHAPTER 5

A Typical Workers Compensation Loss Cost System

- b. Manual rates of the policyholder change only on the anniversary date, subject to the same flexibility now provided for in the NCCI experience rating plans.

Part (a) is required to maintain a centrally-administered experience rating plan, while part (b) is a convenience in maintaining part (a). We propose that both parts of the rule be maintained in this typical system.

The anniversary date rule is assumed to apply in the NCCI calculations of premium at current rate level. If the rule were eliminated, NCCI would need to collect additional data and/or apply approximations to adjust for the change in procedure.

XII. DISTRIBUTION OF INFORMATION TO AGENTS/SALES REPRESENTATIVES

Although insurers and agents/sales representatives may have to change how information is communicated, the situation in workers compensation should not be significantly more complex than other lines of insurance. Companies can provide agents/sales representatives with entire rate manuals or loss cost multipliers and instructions on premium discounts, minimum premiums, and expense constants, if any.

XIII. AVAILABILITY OF NCCI DATA

Summarized data from NCCI, including the information supplied to insurers cited in Section VIII above would be made available to regulators, researchers, and other parties on a request basis. However, distribution of individual policyholder and individual insurer experience would be limited as under the current system.

The issue of allocating costs for the production of this data is an important consideration, but it is not easily considered in isolation from the whole issue of how

CHAPTER 5

A Typical Workers Compensation Loss Cost System

NCCI funds all its operations. In the interests of simplicity, the typical system assumes that regulators will obtain this information free of charge, insurers would receive the "standard" information as part of their membership, and other data for companies and all data for other parties will be obtainable at "cost."

XIV. TRANSITION PROVISIONS

The change from gross rates to loss costs would be implemented gradually on a state-by-state basis as each state is scheduled for a rate review.

The transition would not begin until the implementation of loss costs by ISO late 1992 or early 1993.

The NCCI would begin a series of education and training seminars. Individual seminars would be focused on various target audiences including regulators, small insurers, large insurers, agents/sales representatives, and others. These seminars could be similar to those presented by ISO, but should concentrate on the differences between workers compensation and ISO lines. By then, the various audiences may be more familiar with the general concept of loss costs and how their procedures will need to change. The timing for loss cost implementation should allow for this educational effort.

Even states which have adopted their rating laws or regulations to ISO loss costs may require additional changes to accommodate workers compensation loss costs.
