Abstract

OWL-S is an ontology for describing web services in a way that includes the semantics (meaning) of the web service, including the semantics of its behaviour and the semantics of the static information objects with which it interacts. OWL-S has not been widely used to describe geospatial web services, most of which conform to specifications of the Open Geospatial Consortium (OGC).

This paper describes an approach to the description of OGC web services using OWL-S that takes advantage of the generic OGC specifications to reduce the amount of work involved in creating web service ontologies for OGC web services, and that uses the GetCapabilities document that is provided for all OGC web services.

The approach defines an OWL-S OGC web service ontology that describes the OGC web service specifications (specifically in this case Web Map Service and Web Feature Service), and then shows how a web service ontology may be created by creating instances of the OWL-S OGC ontology and the contents of the GetCapabilities document, thereby reducing the effort involved in creating web service ontologies for OGC web services.

Keywords: web services, ontologies, geospatial, OGC

1 INTRODUCTION

Geospatial web services around the world almost universally conform to standards developed by the Open Geospatial Consortium (OGC¹), a consortium that works towards interoperability for geographic information. These standards define a range of web services with different purposes and functionality, but largely focus on the syntactic aspects of the web services to ensure that it is possible for distributed systems to access and integrate multiple web services from different providers. Little work has been done to comprehensively address the semantic aspects of OGC web services. However, the OGC web services standards each define a document called GetCapabilities that describes the invocation details and functionality of OGC web services with limited semantic information.

Work has also been undertaken in the general information systems community towards developing methods to describe the semantics of web services in ways that allow automated discovery, execution and orchestration of such web services. This work takes the form of web service ontologies: representations that describe what a web service does using a formal specification that can be understood by machines and reasoned about.

This paper proposes a method for the representation of OGC-compliant geospatial web services using OWL-S web service ontologies. This method can be used to automatically populate a web service ontology from the OGC GetCapabilities document, optionally manually augment the web service ontology content with additional semantic information, and use the web service ontology for semantic discovery, execution and workflow chaining of OGC web services.

The structure of the paper is as follows: Section 2 describes a case study that is used to illustrate the work; Section 3 provides background information about semantic descriptions of geospatial web services and their use; Section 4 describes the role and content of the OGC GetCapabilities document; Section 5 presents a summary of the OWL-S web service ontology; Section 6 describes the way in which an OGC GetCapabilities document may be represented in an OWL-S ontology; Section 7 explains how this OWL-S representation may be used by automated systems; Section 8 summarises a demonstration implementation of the approach and Section 9 evaluates and discusses the implications and outcomes of the work.

This paper will provide the reader with an understanding of the semantic issues associated with geospatial web services, as well as showing how OGC web services may be semantically enabled within the bounds of the existing

¹ <http://www.opengeospatial.org/>

specifications and how the functionality provided by web service ontologies may be employed to assist in the automated use of geospatial web services. The work described in this paper was completed as part of the COMPASS² project, a project to develop a geospatial knowledge infrastructure. A number of other papers describe the other aspects of this project, and the interested reader is referred to Stock et al (2009).

2 CASE STUDY

A case study was undertaken to test and evaluate this work. A number of OGC web services were created in the marine science domain with the aim of supporting marine scientists. The goal was to allow scientists to discover these resources and then immediately execute OGC web services without having to take any extra steps, and the approach described in this paper was intended to achieve this end.

The case study particularly focussed around the use of marine instruments, but most of the web services that were created addressed generic aspects of the marine and coastal environment, as these are useful to scientists who study marine instruments, as well as more specific information about the instruments themselves. The generic web services addressed topics including elevation, bathymetry, climate, weather, tides, marine structures and obstructions, conservation and environmental protection. Two geographic areas were covered in the case study: the Severn Estuary near Bristol, UK and the Firth of Forth in Scotland, UK.

For illustrative purposes in this paper, two web services in particular are used:

- a Web Map Service showing bathymetry and elevation in the Firth of Forth and
- a Web Feature Service providing data on climate and oceanography in the Severn Estuary.

The appendices to this paper include the web service ontologies for these two web services.

3 BACKGROUND

3.1 The Benefits of Semantically-Enabled Geospatial Web Services

OGC web services provide a number of functions, some of which are more clearly defined than others. For example, the Web Map Service (de la Beaujardiere, 2006) provides a map or basic feature information in response to a request; a Web Feature Service (Vretanos, 2005) may provide feature

² <http://compass.edina.ac.uk/>

information, or may alternatively allow feature information to be added, edited or deleted; a Web Processing Service (Schut and Whiteside, 2005) may perform almost any geospatial process, with only some core parameters for the request and response defined. In all of these cases, to varying degrees, it is not possible to determine the exact semantics (meaning) of the web service's function or the data it uses from the existing standards, and it is not possible to use the information that is available to automate the process of web service discovery, execution and orchestration.

The most clearly defined of these three examples (Web Map Service) returns a map in response to a request. In this case, the main semantically-undefined component is the data content. Layers are selected by name, but little more is known about the data from a semantic point of view. This means that it is difficult to determine whether two web services provide data that is semantically similar or not. At the other end of the spectrum, very little can be determined from a Web Processing Service using its current representation about what kind of process it performs. Thus one of the most important benefits of semantically-enabled geospatial web services is that they are more meaningfully described so that users (human and machine) are more able to determine whether they provide the function that is required.

Furthermore, the representation of such a description of web service semantics using ontologies provides benefits in terms of automation. Web service ontologies were designed with the intention of describing the most important characteristics of a web service to allow automated discovery, execution and chaining. The formal ontology specification allows such automation to be performed, and in particular, allows inference to be used to perform more intelligent automation of the orchestration process (Gone and Schade, 2008). Thus the use of ontologies augments the functionality that would be available if other descriptive mechanisms were used and permits a wider range of automation.

3.2 Previous Work

A number of efforts have demonstrated and tested the description of geospatial web services with web service ontologies, including SWING (Roman et al 2007), eMerges (Tanasescu et al 2007) and Lutz (2007). However, in these cases, while web services conforming to the OGC standards are described with web service ontologies, the existing GetCapabilities content from the OGC standards is not used. Descriptions are created manually from knowledge of the data set inputs and outputs and axioms may be used to describe pre and postconditions.

Other relevant work that has sought to work together with the existing specifications has examined how OGC web services may be semantically

annotated, and has addressed the role of the GetCapabilities document of the OGC standards. This work proposes methods for adding links in the OGC GetCapabilities document to ontology descriptions, either by including a link from data object descriptions in GetCapabilities to the semantically equivalent concept in a domain ontology, or by linking functionality described in GetCapabilities to the semantically equivalent process in an ontology of web service processes (Maue 2008).

Thus previous work describes OGC web services using web services ontologies alongside the GetCapabilities document, or supplements the GetCapabilities document with links to ontologies. This paper proposes another solution: to store and augment the GetCapabilities content in a web services ontology and use it to assist with the tasks of discovery, execution and orchestration.

Approaching the issue from the other direction, the purpose of web service ontologies is to support dynamic discovery, execution and orchestration of web services. Other work has demonstrated the storage of information about OGC web service specifications and actual web service implementations to support dynamic discovery and execution using feature type catalogues rather than web service ontologies (Stock et al, forthcoming).

4 GETCAPABILITIES

The GetCapabilities document is a central feature of OGC web service specifications. It is mandatory and provides metadata about a web service that implements an OGC specification. A user (human or machine) may execute the GetCapabilities operation on a web service and expect to receive in response a GetCapabilities document that describes the abilities, formats and data offered by the web service. This is intended to allow users to formulate a request after reviewing the GetCapabilities document, and facilitates automated discovery and execution of web services (Whiteside, 2007). The work described in this paper is not concerned with the format of the GetCapabilities request, but only the GetCapabilities document that is the response.

The GetCapabilities document has a set of core components that are included in GetCapabilities documents for all OGC web services, and then each OGC web service specification may nominate additional components that are specific to its own functionality. This paper addresses the core components and the components that are specific to the OGC Web Map Service (WMS) (de la Beaujardiere, 2006) and Web Feature Service (WFS) (Vretanos, 2005). These are described in the following Sections.

4.1 Core Components

The core components of the GetCapabilities document (which apply to all OGC web services) include basic parameters followed by a number of sections with more specific purposes. Beyond this, particular web service specifications may include additional sections. Table 1 shows the core components of the GetCapabilities document for a given web service, documented in the OGC Web Services Common Specification (Whiteside, 2007).

Table 1: Core GetCapabilities Components

Name	Definition	Data Type	Multiplicity ³
version	The version of the specification for the GetCapabilities operation.	Character String.	1
updateSequence	The version of the service metadata document.	Character String.	0..1
ServiceIdentification Section: Information identifying the specific web service.			
serviceType	The type of OGC web service (the specification, for example WMS).	Character String.	1
serviceTypeVersion	The version of the web service specification supported (may be several) by the service.	Character String.	1..*
profile	The application profile supported by the service.	Character String.	0..*
title	The title of the web service, for human consumption.	Character String.	1..*
abstract	A brief narrative description of the web service, for human consumption.	Character String.	0..*
keywords	Unordered list of keywords or phrases.	MD_Keywords (ISO 19115)	0..*
fees	The fees and terms for using the web service.	Character String.	0..1
accessConstraints	Any access constraints that apply on the data from the web service.	Character String.	0..*
ServiceProvider Section: Information about the organisation providing the web service.			
providerName	The name of the organisation providing the web service.	Character String.	1
providerSite	The web site of the service provider.	CI_OnlineResource (ISO 19115)	0..1
serviceContact	Contact name, address and other relevant details.	CI_ResponsibleParty (ISO 19115)	0..1
OperationsMetadata Section: Information about the operations implemented by the service. For each operation (1..*).			
name	The name of the operation.	Character String.	1
DCP	Information for a Distributed Computing Platform supported for this operation.	DCP data structure, consisting of HTTP connect point URLs and get and post URLs and domain constraints (OGC Web Services Common)	1..*
parameter	Details of domains of a parameter for the operation.	DomainType (OGC Web Services Common)	0..*

³ The specifications express multiplicity and optionality separately, but in this table, the two are combined.

constraint	Constraints on a quantity used by this operation that is not a parameter.	DomainType (OGC Web Services Common)	0..*
------------	---	---	------

4.2 Web Feature Service

The OGC Web Feature Service specification (Vretanos, 2005) augments the core components in Section 4.1 with additional components that are specific to the Web Feature Service. Table 2 describes these components.

The Web Feature Service specification also defines valid values for constraints and parameters in the core OperationMetadata Section.

Appendix A contains the GetCapabilities document for the case study severn_co_wfs web service.

Table 2: Additional Web Feature Service Components

Name	Definition	Data Type	Multiplicity ⁴
FeatureType Section: The feature types (and operations on each feature type) that are available for the service. For each feature type (0..*)			
Name	The name of the feature type with namespace.	Qname	1
Title	The human readable title of the feature type (e.g. for menus).	Character String	1
Abstract	An abstract describing the feature type.	Character String	0..1
Keywords	Keywords describing the feature type.	ows:Keywords	0..*
DefaultSRS	The default spatial reference system to be used if an SRS is not specified in the request.	anyURI	0..1
OtherSRS	Other supported spatial reference systems that can be requested.	anyURI	0..*
NoSRS	A label indicating that the feature type has no spatial properties.	CharacterString	0..1
Operations	The set of operations that are supported for the feature type.	OperationsType (enumerated list)	0..*
OutputFormats	The MIME types indicating output formats that may be generated for a feature type.	Character String	0..*
WGS84BoundingBox	The edges of a rectangle or set of rectangles that enclose the data in the feature type.	Ows:WGS84BoundingBox	1..*
MetadataURL	Links to metadata describing the data in the feature type.	MetadataURLType (includes type (e.g. ISO 19115) and format.	0..*

⁴ The specifications express multiplicity and optionality separately, but in this table, the two are combined.

ServesGMLObjectType Section: If the service supports the GetGMLObject operation, the GML object types that are not derived from gml:AbstractFeatureType and that are available from the service, defined in a base GML schema or an application schema. For each object type (0..*)			
Name	The name of the GML object type with namespace.	Qname	1
Title	The human readable title of the GML object type (e.g. for menus).	Character String	1
Abstract	An abstract describing the GML object type.	Character String	0..1
Keywords	Keywords describing the GML object type.	ows:Keywords	0..*
OutputFormats	The MIME types indicating output formats that may be generated for a GML object type.	Character String	0..*
SupportsGMLObjectType Section: The GML object types that the service is capable of serving if it was deployed to serve data from a GML application schema. For each object type (0..*)			
Name	The name of the GML object type with namespace.	Qname	1
Title	The human readable title of the GML object type (e.g. for menus).	Character String	1
Abstract	An abstract describing the GML object type.	Character String	0..1
Keywords	Keywords describing the GML object type.	ows:Keywords	0..*
OutputFormats	The MIME types indicating output formats that may be generated for a GML object type.	Character String	0..*
Filter_Capabilities Section: The parts of the filter encoding specification that are supported by the web service (0..1)			
Spatial_Capabilities	The types of geometry and geometry operations supported by the web service.	Spatial_CapabilitiesType, including Geometry Operands and Spatial Operators (both enumerated lists).	1
Scalar_Capabilities	The types of operations that are supported by the web service relating to comparisons and arithmetic.	Scalar_CapabilitiesType, including Logical Operators, Comparison Operators and Arithmetic Operators and Functions (enumerated lists)	1
Id_Capabilities	The types of identification that are supported by the web service (GMLObjectId and FeatureID).	Id_CapabilitiesType (enumerated list)	1

4.3 Web Map Service

The OGC Web Map Service specification (de la Beaujardiere, 2006) deviates slightly from the format specified for Core elements that was described in Section 4.1. However, much of the content is similar, if named slightly differently. Table 3 identifies the core components in the Web Map Service Specification and maps them to core elements from the OGC Web Services Common Specification, in

the interests of creating a single format for OGC GetCapabilities content that can then be mapped to OWL-S. Table 4 shows the additional elements that do not correspond to the core OWS elements.

Appendix B contains the GetCapabilities document for the case study forth_be web map service.

Table 3: Core WMS Components Mapped to OWS

WMS GetCapabilities	OWS Equivalent
Service Section:	
Title	ServiceIdentification.title
Abstract	ServiceIdentification.abstract
KeywordList	ServiceIdentification.keywords
OnlineResource	ServiceProvider.providerSite
ContactInformation	ServiceProvider.serviceContact, ServiceProvider.providerName
Fees	ServiceIdentification.fees
AccessConstraints	ServiceIdentification.accessConstraints
Capabilities Section:	
Request	OperationsMetadata.name, OperationsMetadata.DCP

Table 4: Additional Web Map Service Components

Name	Definition	Data Type	Multiplicity ⁵
Service Section:			
LayerLimit	The maximum number of layers a client may request in a single request to the web service.	Positive Integer	0..1
MaxWidth	The maximum width of the requested map in a request to the web service.	Positive Integer	0..1
MaxHeight	The maximum height of the requested map in a request to the web service.	Positive Integer	0..1
Capabilities Section:			
Exception	The error-reporting formats supported by the web service.	Character String	1..*
Layer Section (within Capabilities Section):			
For each layer (0..*):			
Name	The name of the layer.	Character String	0..1
Title	The human-readable title of the layer (for menus etc).	Character String	1
Abstract	A description of the layer.	Character String	0..1
KeywordList	A set of keywords describing the layer.	List of Keywords, each Character String	0..1
CRS	An identifier for the coordinate system used by the layer.	Character String	0..*

⁵ The specifications express multiplicity and optionality separately, but in this table, the two are combined.

EX_GeographicBoundingBox	The limits of the layer in latitude and longitude.	wms:longitudeType and latitudeType	0..1
BoundingBox	The limits of the layer in coordinates in a specified map reference system.	x, y, resolution and CRS.	0..*
Dimension	Details of coordinate systems used for temporal, vertical and other dimensions.	Dimension elements listing name, units and other relevant values.	0..*
Attribution	Details of the provider of the layer.	Title, OnlineResource and Logo for the provider.	0..1
AuthorityURL	The URL of an authority used to define elements in the layer (for example, concepts from the Global Change Master Directory).	OnlineResource and name.	0..*
Identifier	The identifier or identifiers defined by a particular authority.	Character String and authority name (references AuthorityURL).	0..*
MetadataURL	A URL referencing more detailed metadata about the layer.	OnlineResource, type (e.g. ISO 19115) and format	0..*
DataURL	The URL of the source data used to create a layer.	OnlineResource and format.	0..*
FeatureListURL	The URL of a list of the features included in a layer.	OnlineResource and format.	0..*
Style	Details of presentation styles available for use with the layer.	The name, title, abstract, legendURL, styleSheetURL and styleURL.	0..*
MinScaleDenominator	The minimum scale denominator for which it is appropriate to display the layer.	Double	0..1
MaxScaleDenominator	The maximum scale denominator for which it is appropriate to display the layer.	Double	0..1
Layer	Layers may be nested within each other to signify classification and grouping of layers.	Layer data type.	0..*
queryable	A flag indicating whether the layer supports the GetFeatureInfo operation.	Boolean	0..1
cascaded	A number indicating how many levels of retransmission have occurred, meaning that the layer obtains some or all of its content from another server.	Integer	0..1
opaque	A flag indicating whether the layer has significant non-data areas that may	Boolean	0..1

	be displayed transparently.		
noSubsets	A flag indicating whether the web service can provide only part of the full bounding box.	Boolean	0..1
fixedWidth	A flag indicating whether the maps can be resized.	Boolean	0..1
fixedHeight	A flag indicating whether the maps can be resized.	Boolean	0..1

5 OWL-S WEB SERVICE ONTOLOGY

OWL-S⁶ is an ontology for the representation of web services that is built using the Web Ontology Language (OWL). OWL⁷ is the dominant method for describing description logic ontologies of all kinds (including for domain concepts, as well as web services), and OWL-S is designed to support web service discovery, invocation, composition and interoperation.

OWL-S has a basic model in which a Service is described using three sub-ontologies:

- A profile, which describes what the service provides to prospective clients (connected to the service via the *presents* property), and is particularly useful for discovery. This includes a description of what is accomplished by the service, limitations on service applicability and quality of service and requirements that the service requester must satisfy to use the service successfully. A service can have any number of profiles.
- A process model, which describes how the service is used (connected to the service via the *describedBy* property) and is used to assist with composition and interoperation. This includes the semantic content of the requests, the conditions under which particular outcomes will occur, and where necessary, the step by step processes leading to those outcomes. A service can be described by no more than one process model.
- A grounding, which describes how a client can interact with the service (connected to the service via the *supports* property) and is used to assist with invocation of the service. This includes a communication protocol, message formats, port numbers and other service specific details of invocation. A service can have a number of groundings.

A major competitor to OWL-S for the description of web service semantics is the Web Service Modelling Ontology (WSMO). This is built using the Web Services Modelling Language (WSML⁸), a language created for the purpose by combining description logics, first order logic and logic programming.

⁶ <http://www.w3.org/Submission/OWL-S/>

⁷ <http://www.w3.org/TR/owl-ref/>

⁸ <http://www.w3.org/Submission/WSML/>

While both ontologies represent similar aspects of web services (process model, grounding and descriptive information), they vary in certain ways (Lara et al 2005). OWL-S was selected for this work, mainly because it is more mature than WSMO, particularly in the area of grounding, which is an important part of the OGC GetCapabilities specification, because it is well supported by tools and because it uses a language that was already being used in the project. However, a mapping between WSMO and OWL-S has been defined (de Brujin and Lausen 2005), and it is expected that it would not be difficult to apply the work in this paper to WSMO.

6 REPRESENTING AN OGC WEB SERVICE IN OWL-S

OGC web services conform to OGC specifications, and thus much of the information stored in OWL-S is identical for all services that conform to a particular specification. Therefore in this work, a generic OWL-S OGC web service ontology was created to store the definitions of the specifications themselves, including the operations, inputs, outputs, preconditions and effects. Appendix C contains the owl file for this ontology. For this work, only Web Feature Service (WFS) and Web Map Service (WMS) were included, and these have semantically fixed operations and parameters (that is, the meaning of the behaviour is the same for all implementations). Thus the only variations for implementations of WFS and WMS are in which operations are supported and in possible parameter values. However, other more generic web service specifications (for example, Web Processing Service (Schut and Whiteside 2005)) allow much more variation in the behaviour of the web service, in which case the generic descriptions in the OWL-S OGC web service ontology would be more limited.

In all cases, a web service ontology is then created for each actual web service implementation. This creates instances of the OWL-S OGC web service ontology to describe the details of the web service, including all of the content of the GetCapabilities document. In the case of more flexible web service specifications like Web Processing Service (Schut and Whiteside 2005), additional semantics would also be required to describe the behaviour of the web service that could not be encapsulated in the generic OWL-S OGC web service ontology.

Specifically, the OWL-S OGC ontology developed in this work (Appendix C) includes classes to describe:

- specialised service types for WFS and WMS;
- the processes that a WFS and WMS may offer and the inputs and outputs that are allowed for each process;

- the bindings between specific operations and their connect points (the URL that may invoke them), and connections between the operations and the processes that they implement.

The web service ontology for each web service implementation specifies the operations that are supported (of the full set included in the OWL-S OGC ontology) and their bindings and describes the feature types and layers in the case of WFS and WMS respectively. Table 5 shows the mappings between the elements of the GetCapabilities document and the different parts of the WFS and WMS GetCapabilities documents, and Appendices D and E contain the web service ontologies for the two case study web services: severn_co_wfs and forth_be respectively.

Table 5: Mappings from GetCapabilities to OWL-S

GetCapabilities Component	WFS	WMS	OWL-S
Core			
version			Service.sourceDocVersion

OWL-S models inputs and outputs as classes, and this approach has been followed in the OWL-S OGC ontology to describe the parameters of the operations. However, many of these inputs and outputs have their own internal structure (for example, the Query input of a WFS), in which case a mixture of properties and classes is used to define the structure of the input or output itself (for example, WFS Query and WFS Feature Collection).

OWL-S provides a WSDL grounding in which an OWL-S file references a WSDL document that describes the grounding, and provides links between the OWL-S components and the WSDL components. However, the work described in this paper is intended to be used with an architecture that stores registry contents in ontologies, and provides mechanisms for storing ontologies, not xml documents (Stock et al, 2009). A RDF version of WSDL has been created (Kopecky, 2006), and the most standards-compliant solution would be to use a grounding based on the WSDL RDF mapping. However, time limitations made this impossible, and a simplified grounding has been used that reflects the OGC grounding. This is depicted diagrammatically in Figure 1.

Figure 1: OGC Http Binding

The semantics of an OGC web service are described using this approach in the following ways:

- the inputs, outputs, preconditions and results describe the semantics of the function of the web service;
- inputs, outputs (and also preconditions and results as part of other expressions) can be connected to concepts in domain ontologies and
- the OWL-S OGC ontology includes a hasTopic property that may connect either an entire web service or a particular aspect thereof (specifically feature types or layers in the case of WFS and WMS respectively) to domain concepts to which they relate.

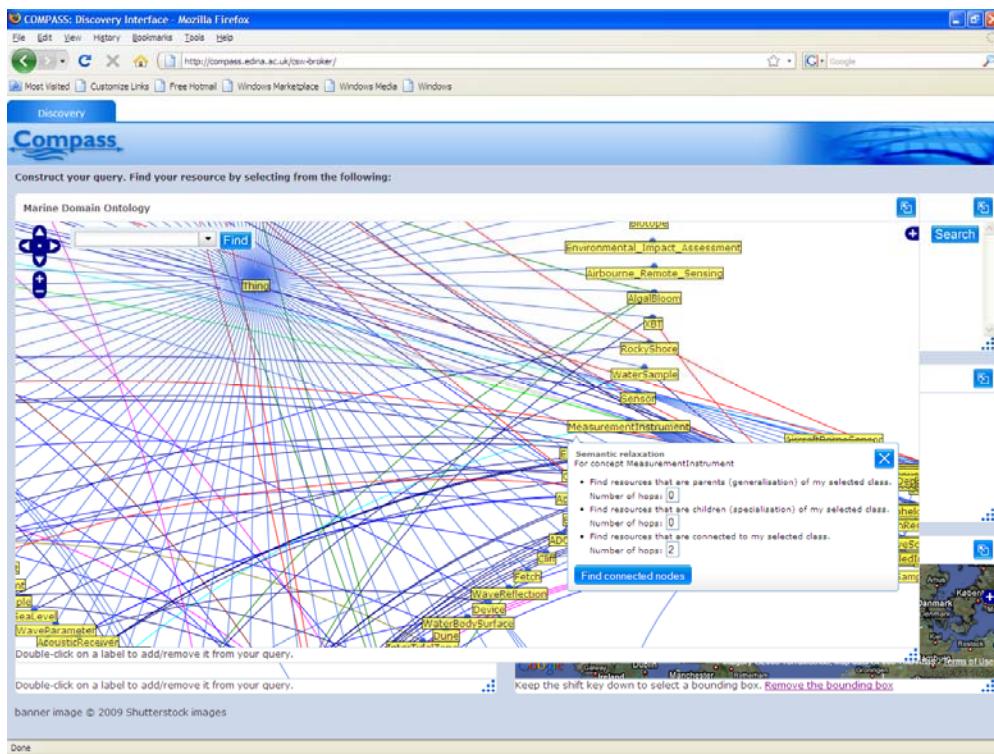

7 AUTOMATED INTERACTION WITH GEOSPATIAL WEB SERVICES THROUGH OWL-S

A particular goal of the project was to allow OGC WMS and WFS to be dynamically executed by users. However, this required that users be prompted for some parameter values. In order to support dynamic execution of the web services, additional elements were added to the OWL-S OGC web service ontology to allow an input form to be dynamically generated. These additional elements appear in green in Figure 1, and have attributes including name, label, size and maxLength, generally conforming to HTML form structure.

8 A DEMONSTRATION IMPLEMENTATION

An application was developed to demonstrate the use of this approach in the marine domain for both discovery and dynamic execution of OGC web services, using a range of web services including those in the case study (Section 2). To demonstrate semantic discovery, an ontology of marine instruments was displayed to allow the user to select concepts of interest, with the option to also search for resources that related to other concepts that were linked to the selected concept (see Figure 2) as parents, children or some other kind of relationship, with a specified number of hops. The query was then executed to search for web services that were connected to the selected domain concepts through the hasTopic property (either directly or through feature types or layers) through an OGC Catalogue Services for the Web interface, using OWL files accessed through Jena middleware.

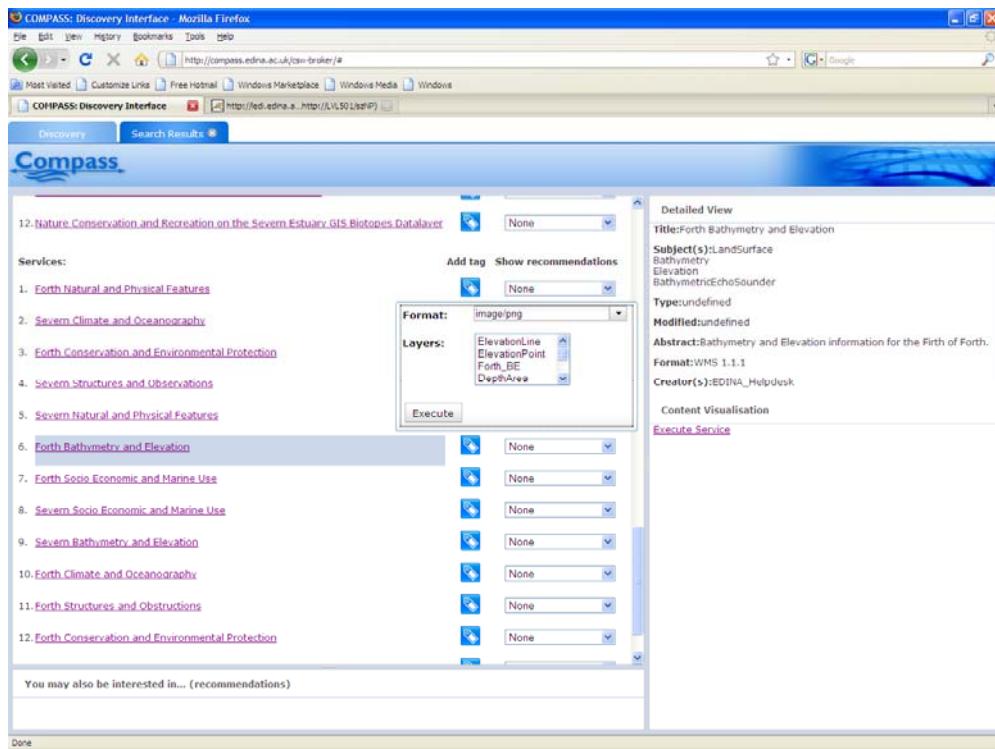

Figure 2: Ontology Browsing

Once the results were displayed, the application demonstrated the dynamic execution of web services. Users could click on web services to execute them.

The application then interrogated the web service ontology to establish whether any of the parameters required for the default operation of that web service link (in the case of a Web Feature Service the default operation was GetFeature, and in the case of a Web Map Service it was GetMap) had attached query models. A form was dynamically created using any linked query models to seek user input (see Figure 3). For example, in the case of the Web Feature Service, a query model was included for the featureType parameter (typically, when a WFS is called using a URL or XML fragment, this parameter is included to indicate for which feature types the user would like to retrieve data). In the web service ontology, the parameter had an attached query model that was an OptionList and an attached Domain that specified the possible values from the set of feature types that the WFS supplied. The user then selected the feature type of interest, and the binding URL (stored in OgcHttpOperation) was combined with the selected feature type to create the call to the web service.

Figure 3: Executing a Web Service

9 DISCUSSION

OWL-S is a cumbersome way to describe web services. In particular, there is significant repetition. Ostensibly, the purposes of expression are different, but in practise in the case of OGC web services, the result is significant duplication of content. This occurs particularly in the definition of parameters. Input and output parameters are defined in three places: for the processes that the web service operations implement; for the grounding of that web service and finally for in the profile of a web services operation. These three descriptions have different purposes, and the sets of inputs and outputs may not be identical (for example, the profile may contain only the parameters that are appropriate to advertise what the web service does), but nevertheless, it is not efficient to define the parameters multiple times. In the implementation described in this paper, the input and output parameters were described fully only in one place (as part of the process definition). They were also described in the grounding only if they had a query model, domain or constraint, and linked them to the process definition as per Figure 1, and they were not described in the Profile at all (but there is a link between the Profile and the Process at operation level, so the parameters could be deduced). This is not technically correct implementation of OWL-S, and the programme that accesses the web service ontology needs to know about this implementation, but it is certainly more practical.

The OWL-S OGC ontology describes the WFS and WMS specifications, and then relies on instances being created to describe actual implementations of those specifications (as in Appendices D and E). Again in the interests of practicality, instances were not created of each parameter for each operation. Instances were created for the operations supported by the web service implementation, and from this the parameters could be deduced from the OWL-S OGC ontology.

It was also difficult to model some of the cardinality constraints for the input and output parameters due to the nature of OWL. In order to avoid massive proliferation of properties, a generic `has<parameter>Component` property was used to describe the subcomponents of non-atomic parameters (for example, Query). This reduced the ability to fully model the constraints on the WFS and WMS parameter values, but reduced the complexity of the ontology.

The OWL-S ontology was used to describe in some detail the data made available by WFS and WMS (feature types and layers respectively). The method was useful in this respect, because it allowed the data offered by the web service to be semantically described, and could potentially be used for intelligent resource discovery and orchestration.

The web service specifications were not fully described for the purposes of this demonstration, as only limited time was available. Specifically:

- results and preconditions were not fully described, and in any case are partially dependent on the implementation, so may not be generalisable to the OWL-S OGC ontology;
- the WSDL grounding was not used (see Section 6) and
- the full complexity of some parameters was not modelled (for example, the subcomponents of Query were not fully described).

The approach proposed here could be automated so that the web service ontologies could be automatically generated from the GetCapabilities documents (it would even be possible to do this dynamically). However, there is limited capacity to automatically generate the semantic links to domain ontology concepts, as this depends on understanding of the web service and the appropriate concepts to link.

In summary, the full use of OWL-S according to its original design to model OGC web service is inefficient and time-consuming. Thus this work adopted a partial implementation of OWL-S that avoided duplication.

The separation of the generic components of the specification in their own ontology (OWL-S OGC), and then the creation of an ontology for each web service instance that created instances of the generic OWL-S OGC ontology proved to make the definition of web service ontologies easier. As can be seen in Appendices C, D and E, the generic OWL-S OGC ontology is many times longer than the ontologies that were created for each web service instance, and thus the burden on the creator of web services is significantly reduced by the presence of the OGC specifications and the creation of the generic OWL-S OGC ontology.

The case study and demonstration application showed that this approach to web service ontologies could be used to discover web services using related domain concepts, and also to dynamically collect user parameters and execute web services. However, the orchestration capabilities of the approach were not tested. It is thought that the work may profitably be extended beyond that presented here to include other OGC specifications (for example, Web Processing Service (Schut and Whiteside, 2005)).

10 CONCLUSIONS

This paper has described an approach to the use of OWL-S to define the semantics of OGC web services. It is a limited approach in that it does not fully employ OWL-S in the way that its designers intended, but it demonstrates a more practical implementation of what is a fairly cumbersome specification.

The work described in this document demonstrates how the OWL-S OGC web service ontology can be used to support discovery and dynamic execution of web services, and shows that web service ontologies can be combined with OGC standards to produce an operable system for semantic enablement of geospatial web services.

  <rdfs:comment rdf:datatype="http://www.w3.org/2001/XMLSchema#string">
    >The Property element is used to specify one or more properties of a feature whose values are to be retrieved by a Web Feature Service. While a Web Feature Service should endeavour to satisfy the exact request specified, in some instance this may not be possible. Specifically, a Web Feature Service must generate a valid GML3 response to a Query operation. The schema used to generate the output may include properties that are mandatory. In order that the output validates, these mandatory properties must be specified in the request. If they are not, a Web Feature Service may add them automatically to the Query before processing it. Thus a client application should, in general, be prepared to receive more properties than it requested. Of course, using the DescribeFeatureType request, a client application can determine which properties are mandatory and request them in the first place.</rdfs:comment>

<rdfs:comment rdf:datatype="http://www.w3.org/2001/XMLSchema#string"

>Boolean attribute valid only for temporal extents (i.e. if attribute name="time"). This attribute, if it either 1 or "true", indicates (a) that temporal data are normally kept current and (b) that the request parameter TIME may include the keyword "current"

instead of an ending value (see C.4.1). Default = 0.</rdfs:comment>
