License Restrictions

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

Warranty Disclaimer

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

Restricted Rights Notice

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and

agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

Hazardous Applications Notice

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Trademark Notice

Oracle, Java, MySQL, and NetSuite are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

Third-Party Content, Products, and Services Disclaimer

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Use of This Documentation

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at

http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit

http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Chapter 1 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed tar files (files with a .tar.gz extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed tax file binary distribution on Unix/Linux platforms. For Linux-generic binary distribution installation instructions with a focus on MySQL security features, refer to the Secure Deployment Guide. For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see Installing MySQL on Microsoft Windows. See How to Get MySQL on how to obtain MySQL in different distribution formats.

MySQL compressed tar file binary distributions have names of the form mysql-VERSION-OS.tar.gz, where VERSION is a number (for example, 5.7.44), and OS indicates the type of operating system for which the distribution is intended (for example, pc-linux-i686 or winx64).

Warnings

• If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as /etc/my.cnf or the /etc/mysql directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related APT guide or Yum guide.

MySQL has a dependency on the libaio library. Data directory initialization
and subsequent server startup steps fail if this library is not installed locally. If
necessary, install it using the appropriate package manager. For example, on
Yum-based systems:

```
$> yum search libaio # search for info
$> yum install libaio # install library
```

Or, on APT-based systems:

```
$> apt-cache search libaio # search for info
$> apt-get install libaio1 # install library
```

- For MySQL 5.7.19 and later: Support for Non-Uniform Memory Access (NUMA) has been added to the generic Linux build, which has a dependency now on the libnuma library; if the library has not been installed on your system, use you system's package manager to search for and install it (see the preceding item for some sample commands).
- SLES 11: As of MySQL 5.7.19, the Linux Generic tarball package format is EL6 instead of EL5. As a side effect, the MySQL client bin/mysql needs libtinfo.so.5.

A workaround is to create a symlink, such as ln -s libncurses.so.5.6 / lib64/libtinfo.so.5 on 64-bit systems or ln -s libncurses.so.5.6 / lib/libtinfo.so.5 on 32-bit systems.

• If no RPM or .deb file specific to your distribution is provided by Oracle (or by your Linux vendor), you can try the generic binaries. In some cases, due to library incompatibilities or other issues, these may not work with your Linux installation. In such cases, you can try to compile and install MySQL from source. See Installing MySQL from Source, for more information and instructions.

To install a compressed tar file binary distribution, unpack it at the installation location you choose (typically /usr/local/mysql). This creates the directories shown in the following table.

Table 1.1 MySQL Installation Layout for Generic Unix/Linux Binary Package

| Directory | Contents of Directory |
|---------------|---|
| bin | mysqld server, client and utility programs |
| docs | MySQL manual in Info format |
| man | Unix manual pages |
| include | Include (header) files |
| lib | Libraries |
| share | Error messages, dictionary, and SQL for database installation |
| support-files | Miscellaneous support files |

Debug versions of the <code>mysqld</code> binary are available as <code>mysqld-debug</code>. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See Installing MySQL from Source.

To install and use a MySQL binary distribution, the command sequence looks like this:

```
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
$> cd /usr/local
$> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
$> ln -s full-path-to-mysql-VERSION-OS mysql
$> cd mysql
$> cd mysql
$> mkdir mysql-files
$> chown mysql:mysql mysql-files
$> chown mysql-files
$> chmod 750 mysql-files
$> bin/mysqld --initialize --user=mysql
$> bin/mysql_ssl_rsa_setup
$> bin/mysql_ssl_rsa_setup
$> bin/mysqld_safe --user=mysql &
# Next command is optional
$> cp support-files/mysql.server /etc/init.d/mysql.server
```

Note

This procedure assumes that you have \mathtt{root} (administrator) access to your system. Alternatively, you can prefix each command using the \mathtt{sudo} (Linux) or \mathtt{pfexec} (Solaris) command.

The <code>mysql-files</code> directory provides a convenient location to use as the value for the <code>secure_file_priv</code> system variable, which limits import and export operations to a specific directory. See Server System Variables.

A more detailed version of the preceding description for installing a binary distribution follows.

Create a mysql User and Group

If your system does not already have a user and group to use for running <code>mysqld</code>, you may need to create them. The following commands add the <code>mysql</code> group and the <code>mysql</code> user. You might want to call the user and group something else instead of <code>mysql</code>. If so, substitute the appropriate name in the following instructions. The syntax for <code>useradd</code> and <code>groupadd</code> may differ slightly on different versions of <code>Unix/Linux</code>, or they may have different names such as <code>adduser</code> and <code>addgroup</code>.

```
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
```

Note

Because the user is required only for ownership purposes, not login purposes, the useradd command uses the -r and -s /bin/false options to create a user that does not have login permissions to your server host. Omit these options if your useradd does not support them.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under /usr/local. The instructions, therefore, assume that you have permission to create files and directories in /usr/local. If that directory is protected, you must perform the installation as root.

```
$> cd /usr/local
```

Obtain a distribution file using the instructions in How to Get MySQL. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. tar can uncompress and unpack the distribution if it has z option support:

```
$> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

The tar command creates a directory named mysql-VERSION-OS.

To install MySQL from a compressed tar file binary distribution, your system must have GNU gunzip to uncompress the distribution and a reasonable tar to unpack it. If your tar program supports the z option, it can both uncompress and unpack the file.

GNU tar is known to work. The standard tar provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU tar, or if available, use a preinstalled version of GNU tar. Usually this is available as <code>gnutar</code>, <code>gtar</code>, or as tar within a GNU or Free Software directory, such as <code>/usr/sfw/bin</code> or <code>/usr/local/bin</code>. GNU tar is available from http://www.gnu.org/software/tar/.

If your tar does not have z option support, use gunzip to unpack the distribution and tar to unpack it. Replace the preceding tar command with the following alternative command to uncompress and extract the distribution:

```
$> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -</pre>
```

Next, create a symbolic link to the installation directory created by tar:

```
$> ln -s full-path-to-mysql-VERSION-OS mysql
```

\$> export PATH=\$PATH:/usr/local/mysql/bin

Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see Postinstallation Setup and Testing.

Chapter 2 Starting the Server for the First Time on Windows

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the noinstall version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of C:\Program Files\MySQL\MySQL Server 5.7. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the shared_memory system variable enabled. Clients can connect through shared memory by using the --protocol=MEMORY option.

For information about which server binary to run, see Selecting a MySQL Server Type.

Testing is best done from a command prompt in a console window (or "DOS window"). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

Note

The database must be initialized before MySQL can be started. For additional information about the initialization process, see <u>Initializing the Data Directory</u>.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.7.44' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the --console option, the server writes diagnostic output to the error log in the data directory (C:\Program Files\MySQL\MySQL Server 5.7\data by default). The error log is the file with the .err extension, and may be set using the --log-error option.

Note

The initial root account in the MySQL grant tables has no password. After starting the server, you should set up a password for it using the instructions in Securing the Initial MySQL Account.

Chapter 3 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the SHUTDOWN privilege can execute a mysqladmin shutdown command. mysqladmin can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a SIGTERM signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a SIGTERM signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

Error: Can't create thread to kill server

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see KILL Statement, in particular for the instructions about killed REPAIR TABLE OF OPTIMIZE TABLE OPERATIONS OF MYISAM tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated because the operation can terminate before completion.

If the server is a source replication server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a KILL QUERY OF KILL CONNECTION statement. See also STOP SLAVE Statement. Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

Note

To guarantee crash safety on the replica, you must run the replica with -- relay-log-recovery enabled.

See also Relay Log and Replication Metadata Repositories).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. InnoDB flushes its buffer pool to disk (unless innodb_fast_shutdown is 2), writes the current LSN to the tablespace, and terminates its own internal threads. MyISAM flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by systemd in response to the code, for platforms on which systemd is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

Chapter 4 Server and Server-Startup Programs

Table of Contents

| 4.1 mysqld — The MySQL Server | ξ |
|--|----|
| 4.2 mysqld_safe — MySQL Server Startup Script | |
| 4.3 mysql.server — MySQL Server Startup Script | 19 |
| 4.4 mysqld multi — Manage Multiple MySQL Servers | 21 |

This section describes mysqld, the MySQL server, and several programs that are used to start the server.

4.1 mysqld — The MySQL Server

mysqld, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

Note

Some installation packages contain a debugging version of the server named <code>mysqld-debug</code>. Invoke this version instead of <code>mysqld</code> for debugging support, memory allocation checking, and trace file support (see Creating Trace Files).

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The mysqld program has many options that can be specified at startup. For a complete list of options, run this command:

```
mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see The MySQL Server. For information about installing MySQL and setting up the initial configuration, see Installing and Upgrading MySQL.

4.2 mysqld_safe — MySQL Server Startup Script

mysqld_safe is the recommended way to start a mysqld server on Unix. mysqld_safe adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On

these platforms, $mysqld_safe$ is not installed because it is unnecessary. For more information, see Managing MySQL Server with systemd.

One implication of the non-use of mysqld_safe on platforms that use systemd for server management is that use of [mysqld_safe] or [safe_mysqld] sections in option files is not supported and might lead to unexpected behavior.

mysqld_safe tries to start an executable named mysqld. To override the default behavior and specify explicitly the name of the server you want to run, specify a --mysqld or --mysqld-version option to mysqld_safe. You can also use --ledir to indicate the directory where mysqld_safe should look for the server.

Many of the options to $mysqld_safe$ are the same as the options to mysqld. See Server Command Options.

Options unknown to mysqld_safe are passed to mysqld if they are specified on the command line, but ignored if they are specified in the [mysqld_safe] group of an option file. See Using Option Files.

mysqld_safe reads all options from the [mysqld], [server], and [mysqld_safe] sections in option files. For example, if you specify a [mysqld] section like this, mysqld_safe finds and uses the --log-error option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, mysqld_safe also reads [safe_mysqld] sections, but to be current you should rename such sections to [mysqld_safe].

mysqld_safe accepts options on the command line and in option files, as described in the following table. For information about option files used by MySQL programs, see Using Option Files.

| Table 4.1 | mysql | d_safe O | ptions |
|-----------|-------|----------|--------|
|-----------|-------|----------|--------|

| Option Name | Description | Introduced | Deprecated |
|---------------------|--|------------|------------|
| basedir | Path to MySQL installation directory | | |
| core-file-size | Size of core file that mysqld should be able to create | | |
| datadir | Path to data directory | | |
| defaults-extra-file | Read named option file in addition to usual option files | | |
| defaults-file | Read only named option file | | |
| help | Display help message and exit | | |
| ledir | Path to directory where server is located | | |
| log-error | Write error log to named file | | |

| Option Name | Description | Introduced | Deprecated |
|--------------------------------|--|------------|------------|
| malloc-lib | Alternative malloc library to use for mysqld | | |
| mysqld | Name of server program to start (in ledir directory) | | |
| mysqld-safe-log- timestamps | Timestamp format for logging | 5.7.11 | |
| mysqld-version | Suffix for server program name | | |
| nice | Use nice program to set server scheduling priority | | |
| no-defaults | Read no option files | | |
| open-files-limit | Number of files that mysqld should be able to open | | |
| pid-file | Path name of server process ID file | | |
| plugin-dir | Directory where plugins are installed | | |
| port | Port number on which to listen for TCP/IP connections | | |
| skip-kill-mysqld | Do not try to kill stray mysqld processes | | |
| skip-syslog | Do not write error messages to syslog; use error log file | | Yes |
| socket | Socket file on which to listen for Unix socket connections | | |
| syslog | Write error messages to syslog | | Yes |
| syslog-tag | Tag suffix for messages written to syslog | | Yes |
| timezone | Set TZ time zone environment variable to named value | | |
| user | Run mysqld as user having name user_name or numeric user ID user_id | | |

• --help

| Command-Line Format | help |
|---------------------|------|
| | |
| Command-Line Format | help |

Display a help message and exit.

• --basedir=dir_name

| Command-Line Format | basedir=dir_name |
|---------------------|------------------|
| Туре | Directory name |

| Command-Line Format | basedir=dir_name |
|---------------------|------------------|
| Туре | Directory name |

The path to the MySQL installation directory.

• --core-file-size=size

| Command-Line Format | core-file-size=size |
|---------------------|---------------------|
| Туре | String |

| Command-Line Format | core-file-size=size |
|---------------------|---------------------|
| Туре | String |

The size of the core file that mysqld should be able to create. The option value is passed to ulimit - c.

• --datadir=dir_name

| Command-Line Format | datadir=dir_name |
|---------------------|------------------|
| Туре | Directory name |

| Command-Line Format | datadir=dir_name |
|---------------------|------------------|
| Туре | Directory name |

The path to the data directory.

• --defaults-extra-file=file_name

| Command-Line Format | defaults-extra-file=file_name |
|---------------------|-------------------------------|
| Туре | File name |

| Command-Line Format | defaults-extra-file=file_name |
|---------------------|-------------------------------|
|---------------------|-------------------------------|

| Туре | File name | |
|------|-----------|--|
| 7 7 | | |

Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server exits with an error. If file_name is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Command-Line Options that Affect Option-File Handling.

• --defaults-file=file_name

| Command-Line Format | defaults-file=file_name |
|---------------------|-------------------------|
| Туре | File name |

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server exits with an error. If file_name is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Command-Line Options that Affect Option-File Handling.

• --ledir=dir_name

| Command-Line Format | ledir=dir_name |
|---------------------|----------------|
| Туре | Directory name |

If mysqld_safe cannot find the server, use this option to indicate the path name to the directory where the server is located.

As of MySQL 5.7.17, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of MYSQLD_OPTS. See Managing MySQL Server with systemd.

--log-error=file_name

| Command-Line Format | log-error=file_name |
|---------------------|---------------------|
| Туре | File name |

Write the error log to the given file. See The Error Log.

• --mysqld-safe-log-timestamps

| Command-Line Format | mysqld-safe-log-timestamps=type | |
|---------------------|---------------------------------|---|
| Introduced | 5.7.11 | |
| Туре | Enumeration 13 | 3 |
| Default Value | utc | |
| Valid Values | system | 1 |

legacy

This option controls the format for timestamps in log output produced by <code>mysqld_safe</code>. The following list describes the permitted values. For any other value, <code>mysqld_safe</code> logs a warning and uses <code>UTC</code> format.

• UTC, utc

ISO 8601 UTC format (same as --log_timestamps=UTC for the server). This is the default.

• SYSTEM, system

ISO 8601 local time format (same as --log_timestamps=SYSTEM for the server).

• HYPHEN, hyphen

YY-MM-DD h:mm:ss format, as in mysgld safe for MySQL 5.6.

• LEGACY, legacy

YYMMDD hh:mm:ss format, as in mysqld_safe prior to MySQL 5.6.

This option was added in MySQL 5.7.11.

• --malloc-lib=[lib name]

| Command-Line Format | malloc-lib=[lib-name] |
|---------------------|-----------------------|
| Туре | String |

The name of the library to use for memory allocation instead of the system malloc() library. As of MySQL 5.7.15, the option value must be one of the directories /usr/lib, /usr/lib64, /usr/lib/i386-linux-gnu, or /usr/lib/x86_64-linux-gnu. Prior to MySQL 5.7.15, any library can be used by specifying its path name, but there is a shortcut form to enable use of the tcmalloc library that is shipped with binary MySQL distributions for Linux in MySQL 5.7. It is possible for the shortcut form not to work under certain configurations, in which case you should specify a path name instead.

Note

As of MySQL 5.7.13, MySQL distributions no longer include a tcmalloc library.

The --malloc-lib option works by modifying the LD_PRELOAD environment value to affect dynamic linking to enable the loader to find the memory-allocation library when mysqld runs:

- If the option is not given, or is given without a value (--malloc-lib=), LD_PRELOAD is not modified and no attempt is made to use tcmalloc.
- Prior to MySQL 5.7.31, if the option is given as --malloc-lib=tcmalloc, mysqld_safe looks for a tcmalloc library in /usr/lib and then in the MySQL pkglibdir location (for example, /usr/local/mysql/lib or whatever is appropriate). If tmalloc is found, its path name is added to the

beginning of the LD_PRELOAD value for mysqld. If tcmalloc is not found, mysqld_safe aborts with an error.

As of MySQL 5.7.31, tcmalloc is not a permitted value for the --malloc-lib option.

- If the option is given as --malloc-lib=/path/to/some/library, that full path is added to the beginning of the LD_PRELOAD value. If the full path points to a nonexistent or unreadable file, mysqld safe aborts with an error.
- For cases where mysqld_safe adds a path name to LD_PRELOAD, it adds the path to the beginning of any existing value the variable already has.

Note

On systems that manage the server using systemd, mysqld_safe is not available. Instead, specify the allocation library by setting LD_PRELOAD in /etc/sysconfig/mysql.

Linux users can use the libtcmalloc_minimal.so included in binary packages by adding these lines to the my.cnf file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a tcmalloc package in /usr/lib. To use a specific tcmalloc library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

• --mysqld=prog_name

| Command-Line Format | mysqld=file_name |
|---------------------|------------------|
| Туре | File name |

The name of the server program (in the ledir directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If mysqld_safe cannot find the server, use the --ledir option to indicate the path name to the directory where the server is located.

As of MySQL 5.7.15, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of MYSQLD_OPTS. See Managing MySQL Server with systemd.

• --mysqld-version=suffix

| Command-Line Format | mysqld-version=suffix |
|---------------------|-----------------------|
| Туре | String |

This option is similar to the --mysqld option, but you specify only the suffix for the server program name. The base name is assumed to be mysqld. For example, if you use --mysqld-

version=debug, mysqld_safe starts the mysqld-debug program in the ledir directory. If the argument to --mysqld-version is empty, mysqld_safe uses mysqld in the ledir directory.

As of MySQL 5.7.15, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of MYSQLD_OPTS. See Managing MySQL Server with systemd.

• --nice=priority

| Command-Line Format | nice=priority |
|---------------------|---------------|
| Туре | Numeric |

Use the nice program to set the server's scheduling priority to the given value.

• --no-defaults

| Command-Line Format | no-defaults |
|---------------------|-------------|
| Туре | String |

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Command-Line Options that Affect Option-File Handling.

• --open-files-limit=count

| Command-Line Format | open-files-limit=count |
|---------------------|------------------------|
| Туре | String |

The number of files that mysqld should be able to open. The option value is passed to ulimit -n.

Note

You must start mysqld_safe as root for this to function properly.

• --pid-file=file_name

| Command-Line Format | pid-file=file_name |
|---------------------|--------------------|
| Туре | File name |

The path name that mysqld should use for its process ID file.

From MySQL 5.7.2 to 5.7.17, mysqld_safe has its own process ID file, which is always named mysqld_safe.pid and located in the MySQL data directory.

• --plugin-dir=dir_name

| Directory frame | Туре | Directory name | |
|-----------------|------|----------------|--|
|-----------------|------|----------------|--|

The path name of the plugin directory.

--port=port_num

| Command-Line Format | port=number |
|---------------------|-------------|
| Туре | Numeric |

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the root operating system user.

• --skip-kill-mysqld

| Command-Line Format | skip-kill-mysqld |
|---------------------|------------------|
|---------------------|------------------|

Do not try to kill stray mysqld processes at startup. This option works only on Linux.

--socket=path

| Command-Line Format | socket=file_name |
|---------------------|------------------|
| Туре | File name |

The Unix socket file that the server should use when listening for local connections.

• --syslog, --skip-syslog

| Command-Line Format | syslog |
|---------------------|--------|
| Deprecated | Yes |

| Command-Line Format | skip-syslog |
|---------------------|-------------|
| Deprecated | Yes |

--syslog causes error messages to be sent to syslog on systems that support the logger program. --skip-syslog suppresses the use of syslog; messages are written to an error log file.

When syslog is used for error logging, the daemon.err facility/severity is used for all log messages.

Using these options to control mysqld logging is deprecated as of MySQL 5.7.5. Use the server log_syslog system variable instead. To control the facility, use the server log_syslog_facility_

17 system variable. See Error Logging to the System Log.

| Deprecated | Yes |
|------------|-----|
|------------|-----|

For logging to syslog, messages from mysqld_safe and mysqld are written with identifiers of mysqld_safe and mysqld, respectively. To specify a suffix for the identifiers, use --syslog-tag=tag, which modifies the identifiers to be mysqld_safe-tag and mysqld-tag.

Using this option to control <code>mysqld</code> logging is deprecated as of MySQL 5.7.5. Use the server <code>log_syslog_tag</code> system variable instead. See Error Logging to the System Log.

• --timezone=timezone

| Command-Line Format | timezone=timezone |
|---------------------|-------------------|
| Туре | String |

Set the TZ time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

• --user={user_name|user_id}

| Command-Line Format | user={user_name user_id} |
|---------------------|--------------------------|
| Туре | String |
| Туре | Numeric |

Run the mysqld server as the user having the name $user_name$ or the numeric user ID $user_id$. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute <code>mysqld_safe</code> with the <code>--defaults-file</code> or <code>--defaults-extra-file</code> option to name an option file, the option must be the first one given on the command line or the option file is not used. For example, this command does not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The <code>mysqld_safe</code> script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Installation Layouts.) <code>mysqld_safe</code> expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which mysqld_safe is invoked). For binary distributions, mysqld_safe looks under its working directory for bin and data directories. For source distributions, it looks for libexec and var directories. This condition should be met if you execute mysqld_safe from your MySQL installation directory (for example, /usr/local/mysql for a binary distribution).
- If the server and databases cannot be found relative to the working directory, mysqld_safe attempts to locate them by absolute path names. Typical locations are /usr/local/libexec and /usr/local/var. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because $mysqld_safe$ tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run $mysqld_safe$ from the MySQL installation directory:

```
cd mysql_installation_directory
bin/mysqld_safe &
```

If mysqld_safe fails, even when invoked from the MySQL installation directory, specify the --ledir and --datadir options to indicate the directories in which the server and databases are located on your system.

mysqld_safe tries to use the sleep and date system utilities to determine how many times per second it has attempted to start. If these utilities are present and the attempted starts per second is greater than 5, mysqld_safe waits 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use mysqld_safe to start mysqld, mysqld_safe arranges for error (and notice) messages from itself and from mysqld to go to the same destination.

There are several mysqld_safe options for controlling the destination of these messages:

- --log-error=file_name: Write error messages to the named error file.
- --syslog: Write error messages to syslog on systems that support the logger program.
- --skip-syslog: Do not write error messages to syslog. Messages are written to the default error log file (host_name.err in the data directory), or to a named file if the --log-error option is given.

If none of these options is given, the default is --skip-syslog.

When mysqld_safe writes a message, notices go to the logging destination (syslog or the error log file) and stdout. Errors go to the logging destination and stderr.

Note

Controlling mysqld logging from $mysqld_safe$ is deprecated as of MySQL 5.7.5. Use the server's native syslog support instead. For more information, see Error Logging to the System Log.

4.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named mysql.server, which starts the MySQL server using mysqld_safe. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

mysql.server is the script name as used within the MySQL source tree. The installed name might be different (for example, mysqld or mysql). In the following discussion, adjust the name mysql.server as appropriate for your system.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, mysql.server and mysqld_safe are not installed because

they are unnecessary. For more information, see Managing MySQL Server with systemd.

To start or stop the server manually using the <code>mysql.server</code> script, invoke it from the command line with start or stop arguments:

```
mysql.server start
mysql.server stop
```

mysql.server changes location to the MySQL installation directory, then invokes mysqld_safe. To run the server as some specific user, add an appropriate user option to the [mysqld] group of the global / etc/my.cnf option file, as shown later in this section. (It is possible that you must edit mysql.server if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs mysqld_safe. If you do this, your modified version of mysql.server may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

mysql.server stop stops the server by sending a signal to it. You can also stop the server manually by executing mysqladmin shutdown.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your /etc/rc* files:

- If you use the Linux server RPM package (MySQL-server-VERSION.rpm), or a native Linux package installation, the mysql.server script may be installed in the /etc/init.d directory with the name mysqld or mysql. See Installing MySQL on Linux Using RPM Packages from Oracle, for more information on the Linux RPM packages.
- If you install MySQL from a source distribution or using a binary distribution format that does not install
 mysql.server automatically, you can install the script manually. It can be found in the supportfiles directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the
 /etc/init.d directory with the name mysql and make it executable:

```
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use chkconfig:

```
chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the mysql script:

```
chkconfig --level 345 mysql on
```

- On FreeBSD, startup scripts generally should go in /usr/local/etc/rc.d/. Install the mysql.server script as /usr/local/etc/rc.d/mysql.server.sh to enable automatic startup. The rc(8) manual page states that scripts in this directory are executed only if their base name matches the *.sh shell file name pattern. Any other files or directories present within the directory are silently ignored.
- As an alternative to the preceding setup, some operating systems also use /etc/rc.local or /etc/init.d/boot.local to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

mysql.server reads options from the [mysql.server] and [mysqld] sections of option files. For backward compatibility, it also reads [mysql_server] sections, but to be current you should rename such sections to [mysql.server].

You can add options for mysql.server in a global /etc/my.cnf file. A typical my.cnf file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql
[mysql.server]
basedir=/usr/local/mysql
```

The <code>mysql.server</code> script supports the options shown in the following table. If specified, they *must* be placed in an option file, not on the command line. <code>mysql.server</code> supports only <code>start</code> and <code>stop</code> as command-line arguments.

Table 4.2 mysql.server Option-File Options

| Option Name | Description | Туре |
|-------------------------|--|----------------|
| basedir | Path to MySQL installation directory | Directory name |
| datadir | Path to MySQL data directory | Directory name |
| pid-file | File in which server should write its process ID | File name |
| service-startup-timeout | How long to wait for server startup | Integer |

• basedir=dir_name

The path to the MySQL installation directory.

• datadir=dir_name

The path to the MySQL data directory.

• pid-file=file_name

The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If this option is not given, <code>mysql.server</code> uses a default value of <code>host_name.pid</code>. The PID file value passed to <code>mysqld_safe</code> overrides any value specified in the <code>[mysqld_safe]</code> option file group. Because <code>mysql.server</code> reads the <code>[mysqld]</code> option file group but not the <code>[mysqld_safe]</code> group, you can ensure that <code>mysqld_safe</code> gets the same value when invoked from <code>mysql.server</code> as when invoked manually by putting the same <code>pid-file</code> setting in both the <code>[mysqld_safe]</code> and <code>[mysqld]</code> groups.

• service-startup-timeout=seconds

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, mysql.server exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

4.4 mysqld_multi — Manage Multiple MySQL Servers

mysqld_multi is designed to manage several mysqld processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, <code>mysqld_multi</code> is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see Managing MySQL Server with systemd.

mysqld_multi searches for groups named [mysqldN] in my.cnf (or in the file named by the --defaults-file option). N can be any positive integer. This number is referred to in the following discussion as the option group number, or GNR. Group numbers distinguish option groups from one another and are used as arguments to mysqld_multi to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the [mysqld] group used for starting mysqld. (See, for example, Starting and Stopping MySQL Automatically.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Running Multiple MySQL Instances on One Machine.

To invoke mysqld_multi, use the following syntax:

```
mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

start, stop, reload (stop and restart), and report indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, mysqld_multi performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named [mysqld17] is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value 10-13 represents groups [mysqld10] through [mysqld13]. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group [mysqld17]:

```
mysqld_multi start 17
```

This command stops several servers, using option groups [mysqld8] and [mysqld10] through [mysqld13]:

```
mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

mysqld_multi searches for option files as follows:

• With --no-defaults, no option files are read.

| Command-Line Format | no-defaults |
|---------------------|-------------|
| Туре | Boolean |
| Default Value | false |

• With --defaults-file=file_name, only the named file is read.

| Command-Line Format | defaults-file=filename |
|---------------------|------------------------|
| Туре | File name |
| Default Value | [none] |

• Otherwise, option files in the standard list of locations are read, including any file named by the -- defaults-extra-file=file_name option, if one is given. (If the option is given multiple times, the last value is used.)

| Command-Line Format | defaults-extra-file=filename |
|---------------------|------------------------------|
| Туре | File name |
| Default Value | [none] |

For additional information about these and other option-file options, see Command-Line Options that Affect Option-File Handling.

Option files read are searched for [mysqld_multi] and [mysqldN] option groups. The [mysqld_multi] group can be used for options to mysqld_multi itself. [mysqldN] groups can be used for options passed to specific mysqld instances.

The [mysqld] or $[mysqld_safe]$ groups can be used for common options read by all instances of mysqld or $mysqld_safe$. You can specify a $--defaults-file=file_name$ option to use a different configuration file for that instance, in which case the [mysqld] or $[mysqld_safe]$ groups from that file are used for that instance.

mysqld_multi supports the following options.

• --help

| Command-Line Format | help |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Display a help message and exit.

• --example

| Command-Line Format | example |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Display a sample option file.

• --log=file_name

| Command-Line Format | log=path |
|---------------------|-----------|
| Туре | File name |

| Default Value | /var/log/mysqld_multi.log |
|---------------|---------------------------|
|---------------|---------------------------|

Specify the name of the log file. If the file exists, log output is appended to it.

• --mysqladmin=prog_name

| Command-Line Format | mysqladmin=file |
|---------------------|-----------------|
| Туре | File name |
| Default Value | [none] |

The mysqladmin binary to be used to stop servers.

• --mysqld=proq name

| Command-Line Format | mysqld=file |
|---------------------|-------------|
| Туре | File name |
| Default Value | [none] |

The <code>mysqld</code> binary to be used. Note that you can specify <code>mysqld_safe</code> as the value for this option also. If you use <code>mysqld_safe</code> to start the server, you can include the <code>mysqld</code> or <code>ledir</code> options in the corresponding <code>[mysqldN]</code> option group. These options indicate the name of the server that <code>mysqld_safe</code> should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.2, "mysqld_safe — <code>MySQL</code> Server Startup Script".) Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir = /opt/local/mysql/libexec
```

• --no-log

| Command-Line Format | no-log |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Print log information to stdout rather than to the log file. By default, output goes to the log file.

• --password=password

| Command-Line Format | password=string |
|---------------------|-----------------|
| Туре | String |
| Default Value | [none] |

The password of the MySQL account to use when invoking mysqladmin. Note that the password value is not optional for this option, unlike for other MySQL programs.

• --silent

| Command-Line Format | silent |
|---------------------|--------|
|---------------------|--------|

| Туре | Boolean |
|---------------|---------|
| Default Value | false |

Silent mode; disable warnings.

• --tcp-ip

| Command-Line Format | tcp-ip |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects stop and report operations.

--user=user_name

| Command-Line Format | user=name |
|---------------------|-----------|
| Туре | String |
| Default Value | root |

The user name of the MySQL account to use when invoking mysqladmin.

--verbose

| Command-Line Format | verbose |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Be more verbose.

--version

| Command-Line Format | version |
|---------------------|---------|
| Туре | Boolean |
| Default Value | false |

Display version information and exit.

Some notes about mysqld_multi:

• Most important: Before using mysqld_multi be sure that you understand the meanings of the options that are passed to the mysqld servers and why you would want to have separate mysqld processes. Beware of the dangers of using multiple mysqld servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system. See Running Multiple MySQL Instances on One Machine.

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific ${\tt mysqld}$ process is started as. Do not use the Unix ${\tt root}$ account for this, unless you ${\tt know}$ what you are doing. See How to Run MySQL as a Normal User.

• Make sure that the MySQL account used for stopping the mysqld servers (with the mysqladmin program) has the same user name and password for each server. Also, make sure that the account has the SHUTDOWN privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common multi_admin account by executing the following commands for each server:

```
$> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See Access Control and Account Management. You have to do this for each mysqld server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as multi_admin from the host where you want to run mysqld multi.

- The Unix socket file and the TCP/IP port number must be different for every mysqld. (Alternatively, if the host has multiple network addresses, you can set the bind_address system variable to cause different servers to listen to different interfaces.)
- The --pid-file option is very important if you are using mysqld_safe to start mysqld (for example, --mysqld=mysqld_safe) Every mysqld should have its own process ID file. The advantage of using mysqld_safe instead of mysqld is that mysqld_safe monitors its mysqld process and restarts it if the process terminates due to a signal sent using kill -9 or for other reasons, such as a segmentation fault.
- You might want to use the --user option for mysqld, but to do this you need to run the
 mysqld_multi script as the Unix superuser (root). Having the option in the option file does not matter;
 you just get a warning if you are not the superuser and the mysqld processes are started under your
 own Unix account.

The following example shows how you might set up an option file for use with <code>mysqld_multi</code>. The order in which the <code>mysqld</code> programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth <code>[mysqldN]</code> groups were intentionally omitted from the example to illustrate that you can have "gaps" in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf
[mysqld_multi]
        = /usr/local/mysql/bin/mysqld_safe
mysald
mysqladmin = /usr/local/mysql/bin/mysqladmin
        = multi_admin
user
          = my_password
password
[mysqld2]
          = /tmp/mysql.sock2
socket
port
         = 3307
pid-file = /usr/local/mysql/data2/hostname.pid2
datadir
          = /usr/local/mysql/data2
language = /usr/local/mysql/share/mysql/english
```

```
= unix_user1
user
[mysqld3]
mysqld
        = /path/to/mysqld_safe
ledir
           = /path/to/mysqld-binary/
mysqladmin = /path/to/mysqladmin
socket = /tmp/mysql.sock3
port
           = 3308
pid-file = /usr/local/mysql/data3/hostname.pid3
datadir = /usr/local/mysql/data3
language = /usr/local/mysql/share/mysql/swedish
user
