DETAIL NATALITY TAPE FILE FOR
1995 DATA**

SPECIAL NOTICE

**THE GEOGRAPHIC CODES WERE CHANGED
EFFECTIVE WITH 1994 DATA TO REFLECT THE
RESULTS OF THE 1990 CENSUS.**

**DETAIL NATALITY FOR PUERTO RICO, VIRGIN
ISLANDS, AND GUAM ARE INCLUDED AS A SEPARATE
DATA SET IN THE PUBLIC-USE FILE**

Public Use Data Tape Documentation - Natality Detail 1995 Data

This tape documentation was prepared in the Division of Vital Statistics. Manju Sharma of the Systems, Programming, and Statistical Resources Branch was responsible for developing the natality documentation and for providing all of the computer programming services necessary to keep it up-to-date. Thomas Dunn assisted Ms. Sharma in updating this documentation.

Sally Curtin of the Reproductive Statistics Branch prepared the Technical Appendix. The Registration Methods Section and the Data Acquisition and Evaluation Branch provided consultation to State Vital Statistics offices regarding collection of birth certificate data.

Questions on the documentation or general questions concerning the natality file should be directed to the of the Systems, Programming, and Statistical Resources Branch, Division of Vital Statistics, NCHS, 6525 Belcrest Road, Room 840, Hyattsville, MD 20782 (301-436-8900).

Questions concerning the Technical Appendix or substantive questions concerning the natality data should be directed to the Reproductive Statistics Branch, Division of Vital Statistics, NCHS, 6525 Belcrest Road, Room 840, Hyattsville, MD 20782 (301-436-8954).

Documentation of the Detail Natality Data File for 1995 Data

Since 1985 natality statistics for all States and the District of Columbia have been based on information from the total file of records. The information is received on computer data tapes coded by the States and provided to the National Center for Health Statistics (NCHS) through the Vital Statistics Cooperative Program. NCHS receives the data for this file from the registration offices of all States, the District of Columbia, and New York City. Natality data for Puerto Rico, Virgin Islands, and Guam are included as separate data-sets in the public-use file.

Natality data for the United States are limited to births occurring within the United States to U.S. residents and nonresidents. Births to nonresidents of the United States are excluded from all tabulations by place of residence. Births occurring to U.S. citizens outside the United States are not included in this file. Natality data for Puerto Rico, Virgin Islands, and Guam are limited to births occurring within the respective territories.

Effective January 1, 1989, a revised U.S. Standard Certificate of Live Birth replaced the 1978 revision. The 1989 revision provides a wide variety of new information on maternal and infant health characteristics, representing a significant departure from previous versions in both content and format. For a more detailed discussion of the revised and new items refer to the technical appendix part of this document.

The Office of Management and Budget revised its designation of metropolitan statistical areas based on figures from the 1990 Census. Effective with the 1990 data file, NCHS has been using these new definitions and codes as indicated in the listing of 320 Metropolitan Statistical Areas (MSA's), Primary Metropolitan Statistical Areas (PMSA's), and New England County Metropolitan Areas (NECMA'S) included in this documentation. There are also 20 Consolidated Metropolitan Statistical Areas (CMSA's), which are made up of PMSA's. Because other geographic changes based on 1990 Census became effective with 1994 data file, the metropolitan statistical area destination were updated as well. Effective with the 1994 data-file there are 311 MSA's, PMSA's, and NECMA'S and 18 CMSA's as indicated in the listing included in this documentation.

NCHS has adopted a new policy on release of vital statistics unit record data files. This new policy was implemented for the 1989 vital event files to prevent the inadvertent disclosure of individuals and institutions. As a result, the files for 1989 and later years do not contain the actual day of the birth or the dates of birth of the mother or father. The geographic detail is also restricted; only counties and cities of 100,000 or more population based on the 1990 Census, as well as metropolitan areas of 100,000 or more population based on the 1990 Census, are identified.

Included in this document are:

1. List of data elements and tape locations.
2. Machine/File/Data Characteristics.
3. Detail Record Layout.
4. Geographic Code Outline.
5. Metropolitan Statistical Areas as adapted for use by NCHS/DVS.
6. Technical Appendix.
7. Table 1. Counts of Births by occurrence and residence for each State
8. Report of Final Natality Statistics, 1995

List of Data Elements and Tape Locations

<u>Data Items</u>	<u>Locations</u>
1. General	
a. Data year	1-4
b. Record type	5
c. Resident status	6
2. Occurrence	
a. NCHS State	16-17
b. Expanded NCHS State	14-15
c. NCHS County	18-20
d. Population size - county	26
e. Division	12
f. Region	11
g. FIPS State	21-22
h. FIPS County	23-25
3. Residence	
a. NCHS State	32-33
b. Expanded NCHS State	30-31
c. NCHS County	34-36
d. NCHS City	37-39
e. Population size - city	40
f. Population size - county	58
g. NCHS PSMA/MSA	347-349
h. Met/Nonmet county	41
i. Division	28
j. Region	27
k. FIPS State	42-43
l. FIPS County	44-46
m. FIPS Place	47-51
n. CMSA	52-53
o. FIPS PSMA/MSA	54-57
4. Prenatal Care	
a. Month began	106-109
b. Number of visits	110-113
c. Adequacy of care recode	93
5. Child	
a. Sex	188-189
b. Number at delivery	201
c. Birthweight	193-199
d. Apgar score	205-207
e. Gestation	181-187, 208-209
f. Month/year of birth	172-173, 176-179
g. Day of week of birth	180

List of Data Elements and Tape Locations

<u>Data Items</u>	<u>Locations</u>
6. Mother	
a. Age	68-76,91-92
b. Race	79-82
c. Marital status	86-87
d. Education	83-85
e. Place of birth	88-90
f. Hispanic origin	77-78
7. Pregnancy History	
a. Born alive, now living	94-95
b. Born alive, now dead	96-97
c. Other terminations	98-99
d. Total birth order	103-105
e. Live birth order	100-102
8. Father	
a. Age	154-157,166-167
b. Race	160-162
c. Hispanic origin	158-159
9. Other Items	
a. Residence reporting flags	307-326
b. Attendant at birth	10
c. Place of delivery	8-9
d. Interval since last live birth	128-132
10. Medical and Health Data	
a. Method of delivery	217-222,224
b. Medical risk factors	225-241
c. Other risk factors	
Tobacco	242-245
Alcohol	246-249
Weight gain during pregnancy	250-252
d. Obstetric procedures	253-259
e. Complications of labor and/or delivery	260-275
f. Abnormal conditions of the newborn	276-284
g. Congenital anomalies	285-306

Machine/File/Data Characteristics:

ALL DATA SETS:

1.	Machine used:	IBM/3081/K
2.	Language used:	PL/I
3.	File organization:	One file, multiple reels
4.	Record format:	Blocked, fixed format
5.	Record mode:	IBM/EBCDIC 8-bit code
6.	Code scheme:	Numeric/Alphabetic/Blanks
7.	Last block:	May be a short block
8.	Record length:	350
9.	Blocksize:	32550

U.S. DATA SET:

1.	Record count:	
2.	Data counts:	ALL BIRTHS:
	a.	By occurrence: 3,903,012
	b.	By residence: 3,899,589
	c.	To foreign residents: 3,423

Primary Metropolitan Statistical Areas and Metropolitan Statistical Areas are those defined by the U.S. Office of Management and Budget (OMB) as of June 30, 1990. For New England, the New England County Metropolitan Areas (NECMA's) are used.

Further back in this document is a list of PMSA's, MSA's, NECMA's, and their component counties.

Vital Statistics Geographic Code Outline for the United States

The following pages show in detail the geographic codes used by the Division of Vital Statistics in the processing of vital event data occurring in the United States. When an event occurs to a nonresident of the United States, residence data are coded only to the "State" level; several western hemisphere countries or the remainder of the world are uniquely identified. Along with the Division of Vital Statistics codes the Federal Information Processing Standards (FIPS) codes are shown for several items. Both sets of codes appear on the vital event public-use files. The Metropolitan Statistical Area codes are effective with the 1994 data year and are based on the 1990 Census.

To aid the user in interpreting the geographic codes, a brief explanation of the codes and of the column headings/abbreviations shown on the following pages are:

State (St): Each State and the District of Columbia are numbered alphabetically. In addition, several unique codes are used to identify nonresidents of the U.S.

County (Cnty): Counties and county equivalents (independent and coextensive cities) are numbered alphabetically within each State.

P/MSA: Primary metropolitan statistical areas and metropolitan statistical areas are those established by the U.S. Office of Management and Budget (OMB) using 1990 Census population counts. For New England, the New England County Metropolitan Areas (NECMA) are used.

M/NM: Metropolitan counties (code 1) are component counties of P/MSA's. Nonmetropolitan counties (code 2) are not part of any P/MSA.

City or place: Cities/places are numbered alphabetically within each State and identify each city with a population of 10,000 or more in 1990.

P/S: Population size code for city of residence based on the 1990 Census. Refer to the code outline given earlier in this document for specific codes and meanings.

Name: Each State, county, and city name is listed along with its respective code. In addition, places used to identify nonresidents of the U.S. are also listed along with their codes.

FIPS: For an explanation of FIPS codes, reference should be made to various National Bureau of Standards (NBS) publications.

So! How do I find Yavapai county, Arizona; or Tupelo city, Mississippi?

Since counties and cities/places are numbered within State, the State and county or the State and city/places codes must be used to select these areas. It is most helpful if the county is known when looking for a particular city since areas are shown by State, county, and city.

Yavapai county, Arizona - State and county codes NCHS: 03 014; FIPS: 04 025.

Tupelo, Mississippi - State and city/place codes NCHS: 25 032; FIPS: 28 74840; or State, county, city/place codes NCHS: 25 041 032; FIPS: 28 081 74840.

Vital Statistics Geographic Code Outline for Puerto Rico, Virgin Islands and Guam

The following pages show in detail the geographic codes used by the Division of Vital Statistics in the processing of vital event data occurring in Puerto Rico, the Virgin Islands, or Guam. When an event occurs to a nonresident of these areas, residence data are coded only to the "State" level; each U.S. state, several western hemisphere countries or the remainder of the world are uniquely identified. Along with the Division of Vital Statistics codes, the Federal Information Processing Standards (FIPS) codes are shown for several items. Both sets of codes appear on the vital event public-use files. Codes are effective with the 1994 data year and are based on results of the 1990 Census.

To aid the user in interpreting the geographic codes, a brief explanation of the codes and of the column headings/abbreviations shown on the following pages are:

Puerto Rico:

State (St): Puerto Rico has its own unique code. In addition, several unique codes are used to identify nonresidents of Puerto Rico.

County (Cnty): Each municipio (county equivalent) is numbered alphabetically.

P/MSA: Primary metropolitan statistical areas and metropolitan statistical areas are those established by the U.S. Office of Management and Budget (OMB) using 1990 Census population counts.

M/NM: Metropolitan counties (code 1) are component counties of P/MSA's. Nonmetropolitan counties (code 2) are not part of any P/MSA.

City or Place: No city/places in Puerto Rico are identified.

Name: Puerto Rico and each municipio are listed along with their respective codes. In addition, places used to identify nonresidents of Puerto Rico are also listed along with their codes.

FIPS: For an explanation of FIPS codes, reference should be made to various National Institute of Standards and Technology (NIST) publications.

Virgin Islands:

State (St): The Virgin Islands has its own unique code. In addition, several unique codes are used to identify nonresidents of the Virgin Islands.

County (Cnty): Several Islands (county equivalent) are numbered alphabetically.

P/MSA: None are identified in the Virgin Islands.

M/NM: No metropolitan areas are identified for the Virgin Islands.

City or Place: City/places are numbered alphabetically within each State and identify each city with a population of 10,000 or more in 1990.

P/S: Population size code for city of residence based on the 1990 Census. Refer to the code outline given earlier in this document for specific codes and meanings.

Name: The Virgin Islands as a whole and several islands are listed along with their respective codes. In addition, places used to identify nonresidents of the Virgin Islands are also listed along with their codes.

Guam:

State (St): Guam has its own unique code. In addition, several unique codes are used to identify nonresidents of Guam.

County (Cnty): None are identified in Guam

P/MSA: None are identified in Guam.

M/NM: No metropolitan areas are identified for Guam.

City or Place: None are identified in Guam.

P/S: No population size groups are identified for Guam.

Name: Guam as a whole is listed along with its respective code. In addition, places used to identify nonresidents of Guam are also listed along with their codes.

1995 Addendum to "Technical Appendix" of Vital Statistics of the United States, 1994" - Volume I, Natality

Apgar Score

In 1995, NCHS collected only the 5-minute Apgar score.

Education of Father

In 1995, NCHS did not collect information on education of the father.

Birth Interval

In 1995, NCHS did not collect information on the date of last live birth. Therefore, there is no information on birth interval for 1995.

Marital Status

In 1995, California and Nevada implemented procedures to help identify the mother's marital status more accurately. In California, procedures that were previously used to help identify the marital status of Asian mothers was extended to Hispanic mothers also. These procedures compare the parents' surnames when they are hyphenated if the parents were born in countries where naming practices can identify the parents' marital status. For Hispanic mothers, if the child is given a double surname of the mother's and father's surnames (either entire surnames or portions of the parents' hyphenated surnames), regardless of the sequence, and the mother is of Hispanic origin, the mother's marital status is coded "Married". In Nevada, marital status information is collected through the electronic birth process even though there is not a direct question on marital status on the printed birth certificate. See the Technical Notes of the Report of Final Natality Statistics, 1995 for more information on special procedures used by States to collect marital status information.

Percent Completeness

See table A for the percent completeness of all items collected from the birth certificate by NCHS for each reporting area.

Residence and Occurrence Data

See table 1 for counts of births by occurrence and residence for every State and the District of Columbia.

Definition of live birth

Every product of conception that gives a sign of life after birth, regardless of the length of the pregnancy, is considered a live birth. This concept is included in the definition set forth by the World Health Organization (1):

Live birth is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which, after such separation, breathes or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached; each product of such a birth is considered liveborn.

This definition distinguishes in precise terms a live birth from a fetal death (see the section on fetal deaths in the Technical Appendix of volume II, Vital Statistics of the United States). In the interest of comparable natality statistics, both the Statistical Commission of the United Nations and the National Center for Health Statistics (NCHS) have adopted this definition (2,3).

History of birth-registration area

The national birth-registration area was proposed in 1850 and established in 1915. By 1933 all 48 States and the District of Columbia were participating in the registration system. The organized territories of Hawaii and Alaska were admitted in 1929 and 1950, respectively; data from these areas were prepared separately until they became States—Alaska in 1959 and Hawaii in 1960. Currently the birth-registration system of the United States covers the 50 States, the District of Columbia, the independent registration area of New York City, Puerto Rico, the U.S.

Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands. However, in the statistical tabulations, ``United States" refers only to the aggregate of the 50 States (including New York City) and the District of Columbia.

The original birth-registration area of 1915 consisted of 10 States and the District of Columbia. The growth of this area is indicated in table 4-1. This table also presents for each year through 1932 the estimated midyear population of the United States and of those States included in the registration system.

Because of the growth of the area for which data have been collected and tabulated, a national series of geographically comparable data before 1933 can be obtained only by estimation. Annual estimates of births have been prepared by P. K. Whelpton for 1909-34 (4). These estimates include adjustments for underregistration and for States that were not part of the birth-registration area before 1933.

Sources of data

Natality statistics

Since 1985 natality statistics for all States and the District of Columbia have been based on information from the total file of records. The information is received on computer data tapes coded by the States and provided to NCHS through the Vital Statistics Cooperative Program. NCHS receives these tapes from the registration offices of all States, the District of Columbia, and New York City. Information for PuertoRico is also received on computer tapes through the Vital Statistics Cooperative Program. Information for the Virgin Islands and Guam is obtained

from microfilm copies of original birth certificates and is based on the total file of records for all years.

Birth statistics for years prior to 1951 and for 1955 are based on the total file of birth records. Statistics for 1951-54, 1956-66, and 1968-71 are based on 50-percent samples except for data for Guam and the Virgin Islands, which are based on all records filed. During the processing of the 1967 data the sampling rate was reduced from 50 percent to 20 percent. For details of this procedure and its consequences for the 1967 data see pages 3-9 to 3-11 in volume I of Vital Statistics of the United States, 1967. From 1972 to 1984 statistics are based on all records filed in the States submitting computer tapes and on a 50-percent sample of records in all other States.

Information for years prior to 1970 for Puerto Rico, the Virgin Islands, and Guam is published in the annual vital statistics reports of the Department of Health of the Commonwealth of Puerto Rico, the Department of Public Health of the Virgin Islands, the Department of Public Health and Social Services of the Government of Guam, and in selected Vital Statistics of the United States annual reports.

U.S. natality data are limited to births occurring within the United States, including those occurring to U.S. residents and nonresidents. Births to nonresidents of the United States have been excluded from all tabulations by place of residence beginning in 1970 (for further discussion see "Classification by occurrence and residence"). Births occurring to U.S. citizens outside the United States are not included in any tabulations in this report. Similarly the data for Puerto Rico, the Virgin Islands, and Guam are limited to births registered in these areas.

Standard certificate of live birth

The U.S. Standard Certificate of Live Birth, issued by the Public Health Service, has served for many years as the principal means of attaining uniformity in the content of the documents used to collect information on births in the United States. It has been modified in each State to the extent required by the particular State's needs or by special provisions of the State's vital statistics law. However, most State certificates conform closely in content to the standard certificate.

The first standard certificate of birth was developed in 1900. Since then, it has been revised periodically by the national vital statistics agency through consultation with State health officers and registrars; Federal agencies concerned with vital statistics; national, State, and county medical societies; and others working in public health, social welfare, demography, and insurance. This procedure has assured careful evaluation of each item for its current and future usefulness for legal, medical, demographic, and research purposes. New items have been added when necessary, and old items have been modified to ensure better reporting or, in some cases, dropped when their usefulness appeared to be limited.

1989 revision--Effective January 1, 1989, a revised U.S. Standard Certificate of Live Birth (figure 4-A) replaced the 1978 revision. This revision provided a wide variety of new information on maternal and infant health characteristics, representing a significant departure from previous versions in both content and format. The most significant format change was the use of checkboxes to obtain detailed medical and health information about the mother and child. It has been demonstrated that this format produces higher quality and more complete information than do open-ended items.

The reformatted items included "Medical Risk Factors for This Pregnancy," which combines the former items "Complications of Pregnancy" and "Concurrent Illnesses or Conditions Affecting

the Pregnancy." "Complications of Labor and/or Delivery" and "Congenital Anomalies of Child" also have been revised from the open-ended format. For each of these items at least 15 specific conditions have been identified.

Several new items were added to the revised certificate. Included are items to obtain information on tobacco and alcohol use during pregnancy, weight gain during pregnancy, obstetric procedures, method of delivery, and abnormal conditions of the newborn. These items can be used to monitor the health practices of the mother that can affect pregnancy and the use of technology in childbirth, and to identify babies with specific abnormal conditions. When combined with other socioeconomic and health data, these items provide a wealth of information relevant to the etiology of low birthweight and other adverse pregnancy outcomes.

Another modification was the addition of a Hispanic identifier for the mother and father. Although NCHS had recommended that States add items to identify the Hispanic or ethnic origin of the newborn's parents, concurrent with the 1978 revision of the U.S. Standard Certificate of Live Birth and reported data from the cooperating States since that year, the item was new to the U.S. Standard Certificate for 1989.

The 1989 revised certificate also provided more detail than previously requested on the birth attendant and place of birth. This permits a more in-depth analysis of the number and characteristics of births by attendant and type of facility and a comparison of differences in outcome. For further discussion see individual sections for each item.

Classification of data

One of the principal values of vital statistics data is realized through the presentation of rates

that are computed by relating the vital events of a class to the population of a similarly defined class. Vital statistics and population statistics, therefore, must be classified according to similarly defined systems and tabulated in comparable groups. Even when the variables common to both, such as geographic area, age, race, and sex, have been similarly classified and tabulated, differences between the enumeration method of obtaining population data and the registration method of obtaining vital statistics data may result in significant discrepancies.

The general rules used to classify geographic and personal items for live births are set forth in "Vital Statistics Classification and Coding Instructions for Live Birth Records, 1994," NCHS Instruction Manual, Part 3a. The classification of certain important items is discussed in the following pages.

Classification by occurrence and residence

Births to U.S. residents occurring outside this country are not reallocated to the United States. In tabulations by place of residence, births occurring within the United States to U.S. citizens and to resident aliens are allocated to the usual place of residence of the mother in the United States, as reported on the birth certificate. Beginning in 1970 births to nonresidents of the United States occurring in the United States are excluded from these tabulations. From 1966 to 1969 births occurring in the United States to mothers who were nonresidents of the United States were considered as births to residents of the exact place of occurrence; in 1964 and 1965 all such births were allocated to "balance of county" of occurrence even if the birth occurred in a city. The change in coding beginning in 1970 to exclude births to nonresidents of the United States from residence data significantly affects the comparability of data with years before 1970 only for Texas.

For the total United States the tabulations by place of residence and by place of occurrence are not identical. Births to nonresidents of the United States are included in data by place of occurrence but excluded from data by place of residence, as previously indicated.

Residence error--A nationwide test of birth-registration completeness in 1950 provided measures of residence error for natality statistics. According to this test, errors in residence reporting for the country as a whole tend to overstate the number of births to residents of urban areas and to understate the number of births to residents of other areas. This tendency has assumed special importance because of a concomitant development--the increased utilization of hospitals in cities by residents of nearby places--with the result that a number of births are erroneously reported as having occurred to residents of urban areas. Another factor that contributes to this overstatement of urban births is the customary procedure of using "city" addresses for persons living outside the city limits. Incomplete residence--Beginning in 1973 where only the State of residence is reported with no city or county specified and the State named is different from the State of occurrence, the birth is allocated to the largest city of the State of residence. Before 1973 such births were allocated to the exact place of occurrence.

Geographic classification

The rules followed in the classification of geographic areas for live births are contained in the instruction manual mentioned previously. The geographic code structure for 1994 is given in another manual, "Vital Records Geographic Classification, 1982," NCHS Instruction Manual , Part 8.

United States--In the statistical tabulations, "United States" refers only to the aggregate of the 50 States and the District of Columbia. Alaska has been included in the U.S. tabulations since 1959 and Hawaii since 1960.

Metropolitan statistical areas--The metropolitan statistical areas and primary metropolitan statistical areas (MSA's and PMSA's) used in this report are those established by the U.S. Office of Management and Budget as of April 1, 1990, and used by the U.S. Bureau of the Census (5) except in the New England States.

Except in the New England States, an MSA has either a city with a population of at least 50,000, or a Bureau of the Census urbanized area of at least 50,000 and a total MSA population of at least 100,000. A PMSA consists of a large urbanized county, or cluster of counties, that demonstrates very strong internal economic and social links and has a population over 1 million. When PMSA's are defined, the large area of which they are component parts is designated a Consolidated Metropolitan Statistical Area (CMSA) (6).

In the New England States the U.S. Office of Management and Budget uses towns and cities rather than counties as geographic components of MSA's and PMSA's. NCHS cannot, however, use this classification for these States because its data are not coded to identify all towns. Instead, the New England County Metropolitan Areas (NECMA's) are used. These areas are established by the U.S. Office of Management and Budget (7) and are made up of county units.

Metropolitan and nonmetropolitan counties-- Independent cities and counties included in MSA's and PMSA's or NECMA's are included in data for metropolitan counties; all other counties are classified as nonmetropolitan.

Population-size groups—Beginning in 1994 vital statistics data for cities and certain other urban places have been classified according to the population enumerated in the 1990 Census of Population. Data are available for individual cities and other urban places of 10,000 or more population. Data for the remaining areas not separately identified are shown in the tables under the heading "Balance of area" or "Balance of county." Classification of areas for 1982-93 was determined by the population enumerated in the 1980 Census of Population. As a result of changes in the enumerated population between 1980 and 1990, some urban places identified in previous reports are no longer included, and a number of other urban places have been added.

Urban places other than incorporated cities for which vital statistics data are shown in this report include the following:

- Each town in New England, New York, and Wisconsin and each township in Michigan, New Jersey, and Pennsylvania that had no incorporated municipality as a subdivision and had either 25,000 inhabitants or more, or a population of 10,000 to 25,000 and a density of 1,000 persons or more per square mile.
- Each county in States other than those indicated above that had no incorporated municipality within its boundary and had a density of 1,000 persons or more per square mile. (Arlington County, Virginia, is the only county classified as urban under this rule.)
- Each place in Hawaii with 10,000 or more population. (There are no incorporated cities in Hawaii.)

Race or national origin

Beginning with the 1989 data year birth data are tabulated primarily by race of mother. In 1988 and prior years the race or national origin shown in tabulations was that of the newborn child. The race of the child was determined for statistical purposes by an algorithm based on the race of the mother and father as reported on the birth certificate. When the parents were of the same race, the race of the child was the same as the race of the parents. When the parents were of different races and one parent was white, the child was assigned to the race of the other parent. When the parents were of different races and neither parent was white, the child was assigned to the race of the father, with one exception--if either parent was Hawaiian, the child was assigned to Hawaiian. If race was missing for one parent, the child was assigned the race of the parent for whom it was reported. When information on race was missing for both parents, the race of the child was considered not stated and the birth was allocated according to rules discussed on page 4 of the Technical Appendix, volume I, Vital Statistics of the United States, 1988. In 1989 the criteria for reporting the race of the parents did not change and continues to reflect the response of the informant (usually the mother).

The most important factor influencing the decision to tabulate births by race of the mother was the decennial revision of the U.S. Standard Certificate of Live Birth in 1989. This revision included many more health questions that are directly associated with the mother, including alcohol and tobacco use, weight gain during pregnancy, medical risk factors, obstetric procedures, complications of labor and/or delivery, and method of delivery. Additionally, many of the other items that have been on the birth certificate for more than two decades also relate directly to the mother, for example, marital status, education level, and receipt of prenatal care. It is more appropriate to use the race of the mother than the race of the child in tabulating these items.

A second factor has been the increasing incidence of interracial parentage. In 1994, 4.4

percent of births were to parents of different races, compared with just 1.7 percent in 1974. About half of these births were to white mothers and fathers of another race. There have been two major consequences of the increasing interracial parentage. One is the effect on birth rates by race. The number of white births under the former procedures has been arbitrarily limited to infants whose parents were both white (or one parent if the race of only one parent was reported). At the same time, the number of births of other races has been arbitrarily increased to include all births to white mothers and fathers of other races. Thus, prior to 1989, if race of mother had been used, birth rates per 1,000 white women in a given age group would have been higher, while comparable rates for black women and women of other races would have been lower. The other consequence of increasing interracial parentage is the impact on the racial differential in various characteristics of births, particularly in cases where there is generally a large racial disparity, such as the incidence of low birthweight. In this instance, the racial differential is larger when the data are tabulated by race of mother rather than by race of child. The same effect has been noted for characteristics such as nonmarital childbearing, preterm births, late or no prenatal care, and low educational attainment of mother.

The third factor influencing the change is the growing proportion of births with race of father not stated, 16 percent in 1994 compared with 9 percent in 1974. This reflects the increase in the proportion of births to unmarried women; in many cases no information is reported on the father. These births were already assigned the race of the mother on a de facto basis. Tabulating births by race of mother provides a more uniform approach, rather than a necessarily arbitrary combination of parental races.

The change in the tabulation of births by race presents some problems when analyzing birth data by race, particularly trend data. The problem is likely to be acute for races other than white and black.

The categories for race or national origin are "White," "Black," "American Indian" (including Aleuts and Eskimos), "Chinese," "Japanese," "Hawaiian," "Filipino," and "Other Asian or Pacific Islander" (including Asian Indian). Before 1992 there was also an "other" category, which is now combined with the "Not stated" category. Before 1978 the category "Other Asian or Pacific Islander" was not identified separately but included with "Other" races. The separation of this category allows identification of the category "Asian or Pacific Islander" by combining the new category "Other Asian or Pacific Islander" with Chinese, Japanese, Hawaiian, and Filipino.

The category "White" comprises births reported as white and births where race is reported as Hispanic. Before 1964 all births for which race or national origin was not stated were classified as white. Beginning in 1964 changes in the procedures for allocating race when race or national origin is not stated have changed the composition of this category. (See discussion on "Race or national origin not stated.")

If the race or national origin of an Asian parent is ill-defined or not clearly identifiable with one of the categories used in the classification (for example, if "Oriental" is entered), an attempt is made to determine the specific race or national origin from the entry for place of birth. If the birthplace is China, Japan, or the Philippines, the race of the parent is assigned to that category. When race cannot be determined from birthplace, it is assigned to the category "Other Asian or Pacific Islander."

Race or national origin not stated—If the race of the mother is not defined or not identifiable with one of the categories used in the classification and the race of the father is known, the race of the father is assigned to the mother. Where information for both parents is missing, the race of the mother is allocated electronically according to the specific race of the mother on the preceding record with a known race of mother. Data for both parents were missing for only 0.5 percent of birth certificates for 1994. Nearly all statistics by race or national origin for the United States as a whole in 1962 and 1963 are affected by a lack of information for New Jersey, which did not report the race of the parents in those years. Birth rates by race for those years are computed on a population base that excluded New Jersey. For the method of estimating the U.S. population by age, sex, and race excluding New Jersey in 1962 and 1963, see page 4-8 in the Technical Appendix of volume I, Vital Statistics of the United States, 1963.

Beginning in 1992, NCHS contracted with seven States with the highest API populations to code births to additional API subgroups. The API subgroups include births to Vietnamese, Asian Indian, Korean, Samoan, Guamanian, and other API women. The seven States included in this reporting area are: California, Hawaii, Illinois, New Jersey, New York, Texas, and Washington. At least two-thirds of the U.S. population of each of these additional API groups lived in the seven-State reporting area(8). The data are available on the detailed natality tapes and CD-ROMs beginning with the 1992 data year. An analytic report based on the 1992 data year is also available upon request(9).

Age of mother

Beginning in 1989 an item on the birth certificate asks for "Date of Birth." In previous years,

“Age (at time of this birth)” was requested. Not all States have revised this item for 1989, and therefore the age of mother either is derived from the reported month and year of birth or coded as stated on the certificate. The age of mother is edited for upper and lower limits. When the age of mother is computed to be under 10 years or 50 years or over, it is considered not stated and is assigned as described below.

Age-specific birth rates are based on populations of women by age, prepared by the U.S. Bureau of the Census. In census years the decennial census counts are used. In intercensal years, estimates of the population of women by age are published by the U.S. Bureau of the Census in Current Population Reports.

The 1990 Census of Population derived age in completed years as of April 1, 1990, from the responses to questions on age at last birthday and month and year of birth, with the latter given preference. In the 1960, 1970, and the 1980 Census of Population, age was also derived from month and year of birth. “Age in completed years” was asked in censuses before 1960. This was nearly the equivalent of the former birth certificate question, which the 1950 test of matched birth and census records confirms by showing a high degree of consistency in reporting age in these two sources (10).

Median age of mother—Median age is the value that divides an age distribution into two equal parts, one-half of the values being less and one-half being greater. Median ages of mothers for 1960 to the present have been computed from birth rates for 5-year age groups rather than from birth frequencies. This method eliminates the effects of changes in the age composition of the childbearing population over time. Changes in the median ages from year to year can thus be attributed solely to changes in the age-specific birth rates.

Not stated date of birth of mother--Beginning in 1964 birth records with date of birth of mother and/or age of mother not stated have had age imputed according to the age of mother from the previous birth record of the same race and total-birth order (total of fetal deaths and live births). (See "Vital Statistics Computer Edits for Natality Data," NCHS Instruction Manual , Part 12, page 9.) In 1963 birth records with age not stated were allocated according to the age appearing on the record previously processed for a mother of identical race and parity (number of live births). For 1960-62 not stated ages were distributed in proportion to the known ages for each racial group. Before 1960 this was done for age-specific birth rates but not for the birth frequency tables, which showed a separate category for age not stated.

Age of father

Age of father is derived from the reported date of birth or coded as stated on the birth certificate. If the age is under 10 years, it is considered not stated and grouped with those cases for which age is not stated on the certificate. Information on age of father is often missing on birth certificates of children born to unmarried mothers, greatly inflating the number of "not stated" in all tabulations by age of father. In computing birth rates by age of father, births tabulated as age of father not stated are distributed in the same proportions as births with known age within each 5-year-age classification of the mother. This procedure is done separately by race. The resulting distributions are summed to form a composite frequency distribution that is the basis for computing birth rates by age of father. This procedure avoids the distortion in rates that would result if the relationship between age of mother and age of father were disregarded.

Live-birth order and parity

Live-birth order and parity classifications shown in this volume refer to the total number of live births the mother has had including the 1994 birth. Fetal deaths are excluded.

Live-birth order indicates what number the present birth represents; for example, a baby born to a mother who has had two previous live births (even if one or both are not now living) has a live-birth order of three. Parity indicates how many live births a mother has had. Before delivery a mother having her first baby has a parity of zero and a mother having her third baby has a parity of two. After delivery the mother of a baby who is a first live birth has a parity of one and the mother of a baby who is a third live birth has a parity of three.

Live-birth order and parity are determined from two items on the birth certificate, "Live births now living" and "Live births now dead."

Not stated birth order--Before 1969 if both of these items were blank, the birth was considered a first birth. Beginning in 1969, births for which the pregnancy history items were not completed have been tabulated as live-birth order not stated. As a result of this revised procedure, 22,686 births in 1969 that would have been assigned to the "First birth order" category under the old rules were assigned to the "Not stated" category.

All births tabulated in the "Not stated birth order" category are excluded from the computation of percents. In computing birth rates by live-birth order, births tabulated as birth order not stated are distributed in the same proportion as births of known live-birth order.

Date of last live birth

The date of last live birth was added to the U.S. Standard Certificate of Live Birth in 1968 for the purpose of providing information on child spacing. The interval since the last live birth is the difference between the date of last live birth and the date of present birth. For an interval to be computed, both the month and year of the last live birth must be valid. This interval is computed only for events to mothers who have had at least one previous live birth.

Births for which the interval since last live birth is not stated are excluded from the computation of percents and means.

Zero interval--An interval of zero months since the last live birth indicates the second born of a set of twins, the second or third born of a set of triplets, and so forth. Births with an interval of zero months are excluded from the computation of mean intervals.

Educational attainment

Data on the educational attainment of both parents were collected beginning in 1968 and tabulated for publication in 1969 for the first time.

The educational attainment of either parent is defined as "the number of years of school completed." Only those years completed in "regular" schools are counted, that is, a formal educational system of public schools or the equivalent in accredited private or parochial schools. Business or trade schools, such as beauty and barber schools, are not considered "regular" schools for the purposes of this item. No attempt has been made to convert years of school completed in foreign school systems, ungraded school systems, and so forth, to equivalent grades in the American school system. Such entries are included in the category "Not stated."

Persons who have completed only a partial year in high school or college are tabulated as having completed the highest preceding grade. For those certificates on which a specific degree is stated, years of school completed is coded to the level at which the degree is most commonly attained; for example, persons reporting B.A., A.B., or B.S. degrees are considered to have completed 16 years of school.

Education not stated--The category "Not stated" includes all records in reporting areas for which there is no information on years of school completed as well as all records for which the information provided is not compatible with coding specifications.

Births tabulated as education not stated are excluded from the computations of percents.

Marital status

Beginning with 1980 data, national estimates of births to unmarried women are derived from two sources. In 1994 marital status was reported directly on the birth certificates of 45 States and the District of Columbia. In the remaining five States, which lack such an item (California, Connecticut, Michigan, Nevada, and New York), marital status is inferred from a comparison of the child's and parents' surnames. This procedure represents a substantial departure from the method used before 1980 to prepare national estimates of births to unmarried women, which assumed that the incidence of births to unmarried women in States with no direct question on marital status was the same as the incidence in reporting States in the same geographic division.

The current method uses related information on the birth certificate to improve the quality of national data on this topic, as well as to provide data for the individual nonreporting States. Beginning

in 1980 a birth in a nonreporting State is classified as occurring to a married woman if the parents' surnames are the same, or if the child's and father's surnames are the same and the mother's current surname cannot be obtained from the informant item of the birth certificate. A birth is classified as occurring to an unmarried woman if the father's name is missing, if the parents' surnames are different, or if the father's and child's surnames are different and the mother's current surname is missing.

Because of the continued substantial increases in nonmarital childbearing throughout the 1980's, the data have been intensively evaluated in each year, 1985-94. There has been continuing concern that the current method might overstate the number of births to unmarried women because it incorporates data based on a comparison of surnames. This is because births to women who have retained their maiden surname as their legal surname after marriage and who are frequently older, well-educated women, would be classified as nonmarital births. Trends based on data incorporating inferential statistics can be compared with trends based on the geographic estimates for the 1980-94 period to show the impact of the two methods. The trends for the two methods are similar for all races combined and for white and black births. Between 1980 and 1994, birth rates for unmarried white women increased 112 percent based on data incorporating inferential information and 116 percent based on the geographic estimates. Birth rates for unmarried black women increased 1 percent based on the inferential data and declined 2 percent based on geographic estimates.

Michigan and Texas births--The number of births to unmarried women in Michigan was underreported during the years 1988-93, but the greatest undercount, numerically, was for 1990-93. Michigan had separate counts of the numbers of births with paternity acknowledgments, but did not include them with the counts of unmarried women based on the general inferential procedures that were provided to NCHS. The underreporting began in 1988, and was about 25 percent for the years

1988-93. In 1993 NCHS reported 36,326 births to unmarried women in Michigan, 26 percent below the number that included paternity affidavits (49,281) (11). Thus, there is a considerable discontinuity in the nonmarital birth data for Michigan from 1993 to 1994. The proportion of nonmarital births reported to NCHS increased from 26 percent to 35 percent.

The number of births to unmarried women in Texas was underreported during the years 1989-93. As a result of legislation passed in 1989, a birth was considered to have occurred to a married woman if the mother provides any information about the father, or if a paternity affidavit has been filed. The measurement of marital status for Texas births improved beginning with the 1994 data year because a direct question on marital status was added to the Texas birth certificate. However, there is a considerable discontinuity in the data for Texas from 1993 to 1994. The proportion of births to unmarried mothers increased from 17 to 29 percent.

No adjustments are made during the data processing for errors in the reporting of marital status on the birth records of the 45 reporting States and the District of Columbia because the extent of this reporting problem is unknown. When marital status is not stated on the birth certificate of a reporting area, the mother is considered married.

When births to unmarried women are reported as second- or higher-order births, it is not known whether the mother was married or unmarried when the previous deliveries occurred, because her marital status at the time of these earlier births is not available from the birth record.

Rates for 1940 and 1950 are based on decennial census counts. Rates for 1955-94 are based on a smoothed series of population estimates (12). Because of sampling error, the original U.S. Bureau of the Census population estimates by marital status fluctuate erratically from year to year; therefore, they have been smoothed so that the rates do not show similar variations. These rates differ

from those published in volumes of Vital Statistics of the United States before 1969, which were based on the original estimates provided annually by the U.S. Bureau of the Census. Birth rates by marital status for 1971-79 have been revised and differ from rates published before 1980 in volumes of Vital Statistics of the United States (see "Computation of rates and other measures").

Place of delivery and attendant at birth

The 1989 revision of the U.S. Standard Certificate of Live Birth included separate categories for freestanding birthing centers, the mother's residence, and clinic or doctor's office as the place of birth. Prior to 1989, place of birth was classified simply as either "In hospital" or "Not in hospital." Births occurring in hospitals, institutions, clinics, centers, or homes were included in the category "In hospital." In this context the word "homes" does not refer to the mother's residence but to an institution, such as a home for unmarried women. Birthing centers were included in either category, depending on each State's assessment of the facility. Beginning in 1989 births occurring in clinics and in birthing centers not attached to a hospital are classified as "Not in hospital." This change in classification may account in part for the lower proportion of "In hospital" births compared with previous years. (The change in classification of clinics should have minor impact because comparatively few births occur in these facilities, but the effect of any change in classification of freestanding birthing centers is unknown.)

Beginning in 1975 the attendant at birth and place of delivery items were coded independently, primarily to permit the identification of the person in attendance at hospital deliveries. The 1989 certificate includes separate classifications for "M.D." (Doctor of Medicine), "D.O." (Doctor of Osteopathy), "C.N.M." (certified nurse midwife), "Other midwife," and "Other" attendants. In earlier

certificates births attended by certified nurse midwives were grouped with those attended by lay midwives. The new certificate also facilitates the identification of home births, births in freestanding birthing centers, and births in clinics or physician offices.

Data for the "In hospital" category for 1975-88 include all births in clinics or maternity centers, regardless of the attendant. Data for 1975-77 published before 1980 included clinic and center births in the category "In hospital" only when the attendant was a physician. Data shown for 1975-77 published after 1980 will, therefore, differ from data published before 1980. As a result of this change, for 1975 an additional 12,352 births are now classified as occurring in hospitals, raising the percent of births occurring in hospitals from 98.7 to 99.1. Similarly, for 1976 the number of births occurring in hospitals increased by 14,133 and the percent in hospitals raised from 98.6 to 99.1; for 1977 the increase is 15,937 and the percent in hospitals raised from 98.5 to 99.0. For 1974 and earlier the "In hospital" category includes all births in hospitals or institutions and births in clinics, centers, or maternity homes only when attended by physicians.

The "Not in hospital" category includes births for which no information is reported on place of birth. Before 1975 births for which the stated place of birth was a "doctor's office" and delivery was by a physician were included in the category "In hospital." Beginning in 1975 these births were tabulated as "Not in hospital" and included with births delivered by physicians in this category. Although the actual number of such births is unknown, the effect of the change is minimal. In 1974, 0.3 percent of all births were delivered by physicians outside of hospitals; in 1975 this proportion was 0.4 percent.

Babies born on the way to or on arrival at the hospital are classified as having been born in the hospital. This may account for some of the hospital births not delivered by physicians or

midwives.

Beginning in 1993, all in-hospital births occurring in Illinois where the attendant was classified as an “other” midwife were changed to certified nurse-midwife. This was necessary because almost all of these births were delivered by midwives certified by the American College of Nurse Midwives but because Illinois does not certify midwives, many of these births were classified as “other” midwives.

Birthweight

Birthweight is reported in some areas in pounds and ounces rather than in grams. However, the metric system has been used in tabulating and presenting the statistics to facilitate comparison with data published by other groups. The categories for birthweight were changed in 1979 to be consistent with the recommendations in the Ninth Revision of the International Classification of Diseases (ICD-9). The categories in gram intervals and their equivalents in pounds and ounces are as follows:

Less than 500 grams = 1 lb 1 oz or less

500-999 grams = 1 lb 2 oz-2 lb 3 oz

1,000-1,499 grams = 2 lb 4 oz-3 lb 4 oz

1,500-1,999 grams = 3 lb 5 oz-4 lb 6 oz

2,000-2,499 grams = 4 lb 7 oz-5 lb 8 oz

2,500-2,999 grams = 5 lb 9 oz-6 lb 9 oz

3,000-3,499 grams = 6 lb 10 oz-7 lb 11 oz

3,500-3,999 grams = 7 lb 12 oz-8 lb 13 oz

4,000-4,499 grams = 8 lb 14 oz-9 lb 14 oz

4,500-4,999 grams = 9 lb 15 oz-11 lb 0 oz

5,000 grams or more = 11 lb 1 oz or more

The ICD-9 defines low birthweight as less than 2,500 grams. This is a shift of 1 gram from the previous criterion of 2,500 grams or less, which was recommended by the American Academy of Pediatrics in 1935 and adopted in 1948 by the World Health Organization in the Sixth Revision of the International Lists of Diseases and Causes of Death.

After data classified by pounds and ounces are converted to grams, median weights are computed and rounded before publication. To establish the continuity of class intervals needed to convert pounds and ounces to grams, the end points of these intervals are assumed to be half an ounce less at the lower end and half an ounce more at the upper end. For example, 2 lb 4 oz-3 lb 4 oz is interpreted as 2 lb 3 1/2 oz-3 lb 4 1/2 oz.

Births for which birthweight is not reported are excluded from the computation of percents and medians.

Period of gestation

The period of gestation is defined as beginning with the first day of the last normal menstrual period (LMP) and ending with the day of the birth. The LMP is used as the initial date because it can be more accurately determined than the date of conception, which usually occurs 2 weeks after the LMP.

Births occurring before 37 completed weeks of gestation are considered to be "preterm" or "premature" for purposes of classification. At 37-41 weeks gestation, births are considered to be "term," and at 42 completed weeks and over, "postterm." These distinctions are according to the ICD-9 definitions.

The 1989 revision of the U.S. Standard Certificate of Live Birth included a new item, "clinical estimate of gestation," that is being compared with length of gestation computed from the LMP date when the latter appears to be inconsistent with birthweight. This is done for normal-weight births of apparently short gestations and very low-birthweight births reported to be full term. The clinical estimate also was used if the date of the LMP was not reported. The period of gestation for 4.1 percent of the births in 1994 was based on the clinical estimate of gestation. For 96 percent of these records the clinical estimate was used because the LMP date was not reported. For the remaining 4 percent the clinical estimate was used because it was compatible with the reported birthweight, whereas the LMP-computed gestation was not. In cases where the reported birthweight was inconsistent with both the LMP-computed gestation and the clinical estimate of gestation, the LMP-computed gestation was used if it was within 5 weeks of the clinical estimate and birthweight was reclassified as "not stated." If the reported birthweight was inconsistent with both the LMP-computed gestation and the clinical estimate of gestation, gestation and birthweight were classified as "not stated" if the LMP-computed gestation was not within 5 weeks of the clinical estimate. These changes result in only a very small discontinuity in the data. For further information on the use of the clinical estimate of gestation see "Computer Edits for Natality Data, Effective 1989," NCHS Instruction Manual , Part 12, pages 34-36.

Before 1981 the period of gestation was computed only when there was a valid month, day,

and year of LMP. However, length of gestation could not be determined from a substantial number of live-birth certificates each year because the day of LMP was missing. Beginning in 1981 weeks of gestation have been imputed for records with missing day of LMP when there is a valid month and year. Each such record is assigned the gestational period in weeks of the preceding record that has a complete LMP date with the same computed months of gestation and the same 500-gram birthweight interval. The effect of the imputation procedure is to increase slightly the proportion of preterm births and to lower the proportion of births at 39, 40, 41, and 42 weeks of gestation. A more complete discussion of this procedure and its implications is presented in a previous report (13).

Because of postconception bleeding or menstrual irregularities, the presumed date of LMP may be in error. In these instances the computed gestational period may be longer or shorter than the true gestational period, but the extent of such errors is unknown.

Month of pregnancy prenatal care began

For those records in which the name of the month is entered for this item, instead of first, second, third, and so forth, the month of pregnancy in which prenatal care began is determined from the month named and the month last normal menses began. For these births, if the item "Date last normal menses began" is not stated, the month of pregnancy in which prenatal care began is tabulated as not stated.

Number of prenatal visits

Tabulations of the number of prenatal visits were presented for the first time in 1972. Beginning in 1989 these data were collected from the birth certificates of all States. Percent

distributions and the median number of prenatal visits exclude births to mothers who had no prenatal care.

Apgar score

One- and 5-minute Apgar scores were added to the U.S. Standard Certificate of Live Birth in 1978 to evaluate the condition of the newborn infant at 1 and 5 minutes after birth. The Apgar score is a useful measure of the need for resuscitation and a predictor of the infant's chances of surviving the first year of life. It is a summary measure of the infant's condition based on heart rate, respiratory effort, muscle tone, reflex irritability, and color. Each of these factors is given a score of 0, 1, or 2; the sum of these 5 values is the Apgar score, which ranges from 0 to 10. A score of 10 is optimum, and a low score raises some doubts about the survival and subsequent health of the infant. In 1994 the reporting area for the 1- and 5-minute Apgar scores was comprised of 48 States and the District of Columbia, accounting for 78 percent of all births in the United States. California and Texas did not have information on Apgar scores on their birth certificate.

Tobacco and alcohol use during pregnancy

The checkbox format allows for classification of a mother as a smoker or drinker during pregnancy and for reporting the average number of cigarettes smoked per day or drinks consumed per week. When smoking and/or drinking status is not reported or is inconsistent with the quantity of cigarettes or drinks reported, the status is changed to be consistent with the amount reported. For example, if the drinking status is reported as "no" but one or more average drinks a week are reported, the mother is classified as a drinker. If the number of cigarettes smoked per day is reported

as one or more, the mother is considered a smoker. When one (or a fraction of one) drink a week is recorded, the mother is classified as a drinker. For records on which the number of drinks or number of cigarettes is reported as a span, for example, 10-15, the lower number is used. The number of drinkers and number of drinks reported on birth certificates are believed to underestimate actual alcohol use.

Data on tobacco use were collected by 46 States, the District of Columbia, and New York City in 1994. This reporting area accounted for 79 percent of all births in the U.S. in 1994. Information on alcohol use was included on the certificates of 48 States and the District of Columbia, accounting for 85 percent of all U.S. births in 1994. California and South Dakota did not include items on alcohol use of their birth certificates.

Weight gained during pregnancy

Weight gain is reported in pounds. A loss of weight is reported as zero gain. Computations of median weight gain were based on ungrouped data. This item was included on the certificates of 49 States and the District of Columbia; California did not report this information. This reporting area excluding California accounted for 86 percent of all births in the United States in 1994.

Medical risk factors for this pregnancy

In 1994 an item on medical risk factors was included on the birth certificates of all States and the District of Columbia, but two States did not report all of the 16 risk factors. Texas did not report genital herpes or uterine bleeding while Kansas did not report Rh sensitization.

The format allows for the designation of more than one risk factor and includes a choice of

``None." Accordingly, if the item is not completed, it is classified as ``Not stated."

The following definitions are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics officials for the Association for Vital Records and Health Statistics (14).

Definitions of medical terms

Anemia--Hemoglobin level of less than 10.0 g/dL during pregnancy or a hematocrit of less than 30 percent during pregnancy.

Cardiac disease--Disease of the heart.

Acute or chronic lung disease--Disease of the lungs during pregnancy.

Diabetes--Metabolic disorder characterized by excessive discharge of urine and persistent thirst; includes juvenile onset, adult onset, and gestational diabetes during pregnancy.

Genital herpes--Infection of the skin of the genital area by herpes simplex virus.

Hydramnios/Oligohydramnios--Any noticeable excess (hydramnios) or lack (oligohydramnios) of amniotic fluid.

Hemoglobinopathy--A blood disorder caused by alteration in the genetically determined molecular structure of hemoglobin (for example, sickle cell anemia).

Hypertension, chronic--Blood pressure persistently greater than 140/90, diagnosed prior to onset of pregnancy or before the 20th week of gestation.

Hypertension, pregnancy-associated--An increase in blood pressure of at least 30 mm Hg systolic or 15 mm Hg diastolic on two measurements taken 6 hours apart after the 20th week of gestation.

Eclampsia--The occurrence of convulsions and/or coma unrelated to other cerebral conditions in

women with signs and symptoms of pre-eclampsia.

Incompetent cervix--Characterized by painless dilation of the cervix in the second trimester or early in the third trimester of pregnancy, with prolapse of membranes through the cervix and ballooning of the membranes into the vagina, followed by rupture of membranes and subsequent expulsion of the fetus.

Previous infant 4,000+ grams--The birthweight of a previous live-born child was over 4,000 grams (8 lbs 13 oz).

Previous preterm or small-for-gestational-age infant--Previous birth of an infant prior to term (before 37 completed weeks of gestation) or of an infant weighing less than the 10th percentile for gestational age using a standard weight-for-age chart.

Renal disease--Kidney disease.

Rh sensitization--The process or state of becoming sensitized to the Rh factor as when an Rh-negative woman is pregnant with an Rh-positive fetus.

Uterine bleeding--Any clinically significant bleeding during the pregnancy, taking into consideration the stage of pregnancy; any second or third trimester bleeding of the uterus prior to the onset of labor.

Obstetric procedures

This item includes six specific obstetric procedures. Birth records with "Obstetric procedures" left blank are considered "not stated." Data on obstetric procedures were reported by all States and the District of Columbia.

The following definitions are adapted and abbreviated from a set of definitions compiled by

a committee of Federal and State health statistics officials for the National Association for Public Health Statistics and Information Systems (NAPHSIS), formerly the Association for Vital Records and Health Statistics (14).

Definitions of medical terms

Amniocentesis--Surgical transabdominal perforation of the uterus to obtain amniotic fluid to be used in the detection of genetic disorders, fetal abnormalities, and fetal lung maturity.

Electronic fetal monitoring--Monitoring with external devices applied to the maternal abdomen or with internal devices with an electrode attached to the fetal scalp and a catheter through the cervix into the uterus, to detect and record fetal heart tones and uterine contractions.

Induction of labor--The initiation of uterine contractions before the spontaneous onset of labor by medical and/or surgical means for the purpose of delivery.

Stimulation of labor--Augmentation of previously established labor by use of oxytocin.

Tocolysis--Use of medications to inhibit preterm uterine contractions to extend the length of pregnancy and therefore avoid a preterm birth.

Ultrasound--Visualization of the fetus and placenta by means of sound waves.

Complications of labor and/or delivery

The checkbox format allows for the selection of 15 specific complications and for the designation of more than 1 complication where appropriate. A choice of "None" is also included. Accordingly, if the item is not completed, it is classified as "not stated."

All States and the District of Columbia included this item on their birth certificates. However, not all of the complications were reported by all reporting States (see table A).

The following definitions are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics officials. (14).

Definitions of medical terms

Febrile--A fever greater than 100 degrees F. or 38 C. occurring during labor and/or delivery.

Meconium, moderate/heavy--Meconium consists of undigested debris from swallowed amniotic fluid, various products of secretion, excretion, and shedding by the gastrointestinal tract; moderate to heavy amounts of meconium in the amniotic fluid noted during labor and/or delivery.

Premature rupture of membranes (more than 12 hours)--Rupture of the membranes at any time during pregnancy and more than 12 hours before the onset of labor.

Abruptio placenta--Premature separation of a normally implanted placenta from the uterus.

Placenta previa--Implantation of the placenta over or near the internal opening of the cervix.

Other excessive bleeding--The loss of a significant amount of blood from conditions other than abruptio placenta or placenta previa.

Seizures during labor--Maternal seizures occurring during labor from any cause.

Precipitous labor (less than 3 hours)--Extremely rapid labor and delivery lasting less than 3 hours.

Prolonged labor (more than 20 hours)--Abnormally slow progress of labor lasting more than 20 hours.

Dysfunctional labor--Failure to progress in a normal pattern of labor.

Breech/Malpresentation--At birth, the presentation of the fetal buttocks rather than the head, or other

malpresentation.

Cephalopelvic disproportion--The relationship of the size, presentation, and position of the fetal head to the maternal pelvis prevents dilation of the cervix and/or descent of the fetal head.

Cord prolapse--Premature expulsion of the umbilical cord in labor before the fetus is delivered.

Anesthetic complications--Any complication during labor and/or delivery brought on by an anesthetic agent or agents.

Fetal distress--Signs indicating fetal hypoxia (deficiency in amount of oxygen reaching fetal tissues).

Abnormal conditions of the newborn

This item provides information on eight specific abnormal conditions. More than one abnormal condition may be reported for a given birth or "None" may be selected. If the item is not completed it is tabulated as "not stated." This item was included on the birth certificates of all States and the District of Columbia in 1994. However, several States did not include all conditions (see table A).

The following definitions are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics. (14).

Definitions of medical terms

Anemia--Hemoglobin level of less than 13.0 g/dL or a hematocrit of less than 39 percent.

Birth injury--Impairment of the infant's body function or structure due to adverse influences that occurred at birth.

Fetal alcohol syndrome--A syndrome of altered prenatal growth and development occurring in infants

born of women who consumed excessive amounts of alcohol during pregnancy.

Hyaline membrane disease/RDS--A disorder primarily of prematurity, manifested clinically by respiratory distress and pathologically by pulmonary hyaline membranes and incomplete expansion of the lungs at birth.

Meconium aspiration syndrome--Aspiration of meconium by the fetus or newborn, affecting the lower respiratory system.

Assisted ventilation (less than 30 minutes)--A mechanical method of assisting respiration for newborns with respiratory failure.

Assisted ventilation (30 minutes or more)--Newborn placed on assisted ventilation for 30 minutes or longer.

Seizures--A seizure of any etiology.

Congenital anomalies of child

The data provided in this item relate to 21 specific anomalies or anomaly groups. It is well documented that congenital anomalies, except for the most visible and most severe, are incompletely reported on birth certificates. The completeness of reporting specific anomalies depends on how easily they are recognized in the short time between birth and birth registration. Forty-nine States and the District of Columbia included this item on their birth certificates (New Mexico and New York City did not). This reporting area included 96 percent of all births in the United States in 1994. The format allows for the identification of more than one anomaly including a choice of "None" should no anomalies be evident. The category "not stated" includes birth records for which the item is not completed.

The following definitions are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics officials. (14).

Definitions of medical terms

Anencephalus--Absence of the cerebral hemispheres.

Spina bifida/meningocele--Developmental anomaly characterized by defective closure of the bony encasement of the spinal cord, through which the cord and meninges may or may not protrude.

Hydrocephalus--Excessive accumulation of cerebrospinal fluid within the ventricles of the brain with consequent enlargement of the cranium.

Microcephalus--A significantly small head.

Other central nervous system anomalies--Other specified anomalies of the brain, spinal cord, and nervous system.

Heart malformations--Congenital anomalies of the heart.

Other circulatory/respiratory anomalies--Other specified anomalies of the circulatory and respiratory systems.

Rectal atresia/stenosis--Congenital absence, closure, or narrowing of the rectum.

Tracheo-esophageal fistula/Esophageal atresia--An abnormal passage between the trachea and the esophagus; esophageal atresia is the congenital absence or closure of the esophagus.

Omphalocele/gastroschisis--An omphalocele is a protrusion of variable amounts of abdominal viscera from a midline defect at the base of the umbilicus. In gastroschisis, the abdominal viscera protrude through an abdominal wall defect, usually on the right side of the umbilical cord insertion.

Other gastrointestinal anomalies--Other specified congenital anomalies of the gastrointestinal system.

Malformed genitalia--Congenital anomalies of the reproductive organs.

Renal agenesis--One or both kidneys are completely absent.

Other urogenital anomalies--Other specified congenital anomalies of the organs concerned in the production and excretion of urine, together with organs of reproduction.

Cleft lip/palate--Cleft lip is a fissure of elongated opening of the lip; cleft palate is a fissure in the roof of the mouth. These are failures of embryonic development.

Polydactyly/syndactyly/adactyly--Polydactyly is the presence of more than five digits on either hands and/or feet; syndactyly is having fused or webbed fingers and/or toes; adactyly is the absence of fingers and/or toes.

Club foot--Deformities of the foot, which is twisted out of shape or position.

Diaphragmatic hernia--Herniation of the abdominal contents through the diaphragm into the thoracic cavity usually resulting in respiratory distress.

Other musculoskeletal/integumental anomalies--Other specified congenital anomalies of the muscles, skeleton, or skin.

Down's syndrome--The most common chromosomal defect with most cases resulting from an extra chromosome (trisomy 21).

Other chromosomal anomalies--All other chromosomal aberrations.

Method of delivery

The birth certificate contains a checkbox item on method of delivery. The choices include vaginal delivery, with the additional options of forceps, vacuum, and vaginal birth after previous cesarean section (VBAC), as well as a choice of primary or repeat cesarean. When only forceps,

vacuum, or VBAC is checked, a vaginal birth is assumed. In 1994 this information was collected from the birth certificates of all States and the District of Columbia.

Several rates are computed for method of delivery. The overall cesarean section rate or total cesarean rate is computed as the proportion of all births that were delivered by cesarean section. The primary cesarean rate is a measure that relates the number of women having a primary cesarean delivery to all women giving birth who have never had a cesarean delivery. The denominator for this rate includes all births, less those with method of delivery classified as repeat cesareans and vaginal birth after previous cesarean. The rate for vaginal birth after previous cesarean (VBAC) delivery is computed by relating all VBAC deliveries to the sum of VBAC and repeat cesarean deliveries, that is, to women with a previous cesarean section. VBAC rates for first births exist because the rates are computed on the basis of previous pregnancies, not just live births.

Hispanic parentage

The 1989 revision of the U.S. Standard Certificate of Live Births includes items to identify the Hispanic origin of the parents. Concurrent with the 1978 revision of the U.S. Certificate of Live Birth, NCHS recommended that items to identify the Hispanic or ethnic origin of the newborn's parents be included on birth certificates and has tabulated and evaluated these data from the reporting States. All 50 States and the District of Columbia reported Hispanic origin of the parents for 1994.

In computing birth and fertility rates for the Hispanic population, births with origin of mother not stated are included with non-Hispanic births rather than being distributed. Thus, rates for the Hispanic population are underestimates of the true rates to the extent that the births with origin of mother not stated (1.1 percent in 1994) were actually to Hispanic mothers. The population with

origin not stated was imputed. The effect on the rates is believed to be small.

Quality of data

Although vital statistics data are useful for a variety of administrative and scientific purposes, they cannot be correctly interpreted unless various qualifying factors and methods of classification are taken into account. The factors to be considered depend on the specific purposes for which the data are to be used. It is not feasible to discuss all the pertinent factors in the use of vital statistics tabulations, but some of the more important ones should be mentioned.

Most of the factors limiting the use of data arise from imperfections in the original records or from the impracticability of tabulating these data in very detailed categories. These limitations should not be ignored, but their existence does not lessen the value of the data for most general purposes.

Completeness of registration

An estimated 99 percent of all births occurring in the United States in 1994 were registered; for white births registration was 99.4 percent complete and for all other births, 98.6 percent complete. These estimates are based on the results of the 1964-68 test of birth-registration completeness according to place of delivery (in or out of hospital) and race and on the 1989 proportions of births in these categories. The primary purpose of the test was to obtain current measures of registration completeness for births in and out of hospital by race on a national basis. Data for States were not available as they had been from the previous birth-registration tests in 1940 and 1950. A detailed discussion of the method and results of the 1964-68 birth-registration test is available (15).

The 1964-68 test has provided an opportunity to revise the estimates of birth-registration completeness for the years since the previous test in 1950 to reflect the improvement in registration. This has been done using registration completeness figures from the two tests by place of delivery and race. Estimates of registration completeness for four groups (based on place of delivery and race) for 1951-65 were computed by interpolation between the test results. (It was assumed that the data from the more recent test are for 1966, the midpoint of the test period.) The results of the 1964-68 test are assumed to prevail for 1966 and later years. These estimates were used with the proportions of births registered in these categories to obtain revised numbers of births adjusted for underregistration for each year. The overall percent of birth-registration completeness by race was then computed.

Data adjusted for underregistration for 1951-59 have been revised to be consistent with the 1964-68 test results and differ slightly from data shown in annual reports for years before 1969. For these years the published number of births and birth rates for both racial groups have been revised slightly downward because the 1964-68 test indicated that previous adjustments to registered births were slightly inflated. Because registration completeness figures by age of mother and by live-birth order are not available from the 1964-68 test, it must be assumed that the relationships among these variables have not changed since 1950.

Discontinuation of adjustment for underregistration, 1960--

Adjustment for underregistration of births was discontinued in 1960 when birth registration for the United States was estimated to be 99.1 percent complete. This removed a bias introduced into age-specific rates when adjusted births classified by age were used. Age-specific rates are calculated by dividing the number of births to an age group of mothers by the population of women in that age

group. Tests have shown that population figures are likely to be understated through census undercounts; these errors compensate for underregistration of births. Adjustment for underregistration of births, therefore, removes the compensating effect of underenumeration, biasing the age-specific rates more than when uncorrected birth and population data are used. (For further details see page 4-11 in the Technical Appendix of volume I, Vital Statistics of the United States, 1963.)

The age-specific rates used in the cohort fertility tables are an exception to the above statement. These rates are computed from births corrected for underregistration and population estimates adjusted for underenumeration and misstatement of age.

Adjusted birth and population estimates are used for the cohort rates because they are an integral part of a series of rates, estimated with a consistent methodology. It was considered desirable to maintain consistency with respect to the cohort rates, even though it means that they will not be precisely comparable with other rates shown for 5-year age groups.

Completeness of reporting

Interpretation of these data must include evaluation of item completeness. The percent "not stated" is one measure of the quality of the data. Completeness of reporting varies among items and States. See table A for the percent of birth records on which specified items were not stated.

Quality control procedures

States in the Vital Statistics Cooperative Program are required to have an error rate of less

than 2.0 percent for each item for 3 consecutive data months during the initial qualifying period. Once a State is qualified, NCHS monitors the quality of data received. This was achieved through independent verification of a sample of records for some States as well as comparing the State data with data from previous years. In addition, there is verification at the State level before NCHS is sent the data.

After the coding is completed, counts of the taped records are balanced against control totals for each shipment of records from a registration area. Impossible codes are eliminated during the editing processes on the computer and corrected on the basis of reference to the source record or adjusted by arbitrary code assignment. All subsequent operations involved in tabulation and table preparation are verified during computer processing or by statistical clerks.

Small frequencies

The numbers of births reported for an area represent complete counts. As such, they are not subject to sampling error, although they are subject to errors in the registration process. However, when the figures are used for analytical purposes, such as the comparison of rates over a period of time or for different areas, the number of events that actually occurred may be considered as one of a large series of possible results that could have arisen under the same circumstances. The probable range of values may be estimated from the actual figures according to certain statistical assumptions.

In general, distributions of vital events may be assumed to follow the binomial distribution. Estimates of standard errors and tests of significance under this assumption are described in most standard statistics texts. When the number of events is large, the relative standard error, expressed as a percent of the number or rate, is usually small.

When the number of events is small (fewer than 100) and the probability of such an event is small, considerable caution must be observed in interpreting the conditions described by the figures. Events of rare nature may be assumed to follow a Poisson probability distribution. For this distribution, a simple approximation may be used to estimate the error as follows:

If N is the number of births and R is the corresponding rate, the chances are 19 in 20 that

1. The "true" number of events lies between

$$N - 2\sqrt{N} \text{ and } N + 2\sqrt{N}$$

2. The "true" rate lies between

$$R - 2\frac{R}{\sqrt{N}} \text{ and } R + 2\frac{R}{\sqrt{N}}$$

If the rate R_1 corresponding to N_1 events is compared with the rate R_2 corresponding to N_2 events, the difference between the two rates may be regarded as statistically significant if it exceeds

$$2 \sqrt{\frac{R_1^2}{N_1} + \frac{R_2^2}{N_2}}$$

For example, suppose that the observed birth rate for area A was 15.0 per 1,000 population and that this rate was based on 50 recorded births. Given prevailing conditions, the chances are 19 in 20 that the "true" or underlying birth rate for that area lies between 10.8 and 19.2 per 1,000 population. Let it be further supposed that the birth rate for area A of 15.0 per 1,000 population is being compared with a rate of 20.0 per 1,000 population for area B, which is based on 40 recorded births. Although the difference between the rates for the two areas is 5.0, this difference is less than twice the standard error of the difference

$$2 \sqrt{\frac{(15.0)^2}{50} + \frac{(20.0)^2}{40}}$$

of the two rates that is computed to be 7.6. From this, it is concluded that the difference between the rates for the two areas is not statistically significant.

Computation of rates and other measures

Population bases

The rates shown in this report were computed on the basis of population statistics prepared by the U.S. Bureau of the Census. Rates for 1940, 1950, 1960, 1970, 1980, and 1990 are based on the population enumerated as of April 1 in the censuses of those years. Rates for all other years are based on the estimated midyear (July 1) population for the respective years. Birth rates for the United States, individual States, and metropolitan areas are based on the total resident populations of the respective areas. Except as noted these populations exclude the Armed Forces abroad but include the Armed Forces stationed in each area.

The resident population of the birth- and death-registration States for 1900-32 and for the United States for 1900-94 is shown in table 4-1. In addition, the population including Armed Forces abroad is shown for the United States. Table B shows the sources for these populations.

In both the 1980 and 1990 censuses, a substantial number of persons did not specify a racial group that could be classified as any of the White, Black, American Indian, Eskimo, Aleut, Asian, or Pacific Islander categories on the census form (16). In 1980 the number of persons of "other" race was 6,758,319; in 1990 it was 9,804,847. In both censuses, the large majority of these persons were of Hispanic origin (based on response to a separate question on the form), and many wrote in their Hispanic origin, or Hispanic origin type (for example, Mexican, Puerto Rican) as their race. In both 1980 and 1990, persons of unspecified race were allocated to one of the four tabulated racial groups (white, black, American Indian, Asian or Pacific Islander), based on their response to the Hispanic origin question. These four race categories conform with the 1979 edition of OMB Directive 15 which mandates that race data must contain at least these 4 categories. These categories are also more consistent with the race categories in vital statistics.

In the allocation of unspecified race was carried out using cross-tabulations of age, sex, race, type of Hispanic origin, and county of residence. Persons of Hispanic origin and unspecified race were allocated to either white or black, based on their Hispanic origin type. Persons of "other" race and Mexican origin were categorically assumed to be white, while persons in other Hispanic categories were distributed to white and black pro rata within the county-age-sex group. For "other-not-specified" persons who were not Hispanic, race was allocated to white, black, or Asian and Pacific Islander, based on proportions gleaned from sample data. The 20-percent sample (respondents who were enumerated on the longer census form) provided a highly detailed coding of race, which allowed identification of otherwise unidentifiable responses with a specified race category. Allocation proportions were thus established at the State level, which were used to distribute the non-Hispanic persons of "other" race in the 100-percent tabulations.

In 1990 the race modification procedure was carried out using individual census records. Persons whose race could not be specified were assigned to a racial category using a pool of "race donors," which was derived from persons of specified race and the identical response to the Hispanic origin question within the auspices of the same Census District Office. As in 1980, the underlying assumption was that the Hispanic origin response was the major criterion for allocating race. Unlike 1980, persons of Hispanic origin, including Mexican, could be assigned to any racial group, rather than white or black only, and the non-Hispanic component of "other" race was allocated primarily on the basis of geography (District Office), rather than detailed characteristic.

The means by which respondent's age was determined were fundamentally different in the two censuses; therefore, the problems that necessitated the modification were different. In 1980 respondents reported year of birth and quarter of birth (within year) on the census form. When census

results were tabulated, persons born in the first quarter of the year (before April 1) had age equal to 1980 minus year of birth, while persons born in the last three quarters had age equal to 1979 minus year of birth.

In 1990 the quarter year of birth was not reported on the census form, so that direct determination of age from year of birth was impossible. In 1990 census publications age is based on respondents' direct reports of age at last birthday. This definition proved inadequate for postcensal estimates, because it was apparent that many respondents had reported their age at time of either completion of the census form or interview by an enumerator, which could occur several months after the April 1 reference data. As a result, age was biased upward. Modification was based on a respecification of age, for most individual respondents, by year of birth, with allocation to first quarter (persons aged 1990 minus year of birth) and last three quarters (aged 1989 minus year of birth) based on a historical series of registered births by month. This process partially restored the 1980 logic for assignment of age. It was not considered necessary to correct for age overstatement and heaping in 1990, because the availability of age and year of birth on the census form provided elimination of spurious year-of-birth reports in the census data before modification occurred.

Populations for 1994—The population of the United States by age, sex, race, and Hispanic origin are shown in the Census Bureau report, United States population estimates by age, sex, race and Hispanic origin: 1990 to 1994. U.S. Bureau of the Census. PPL-21. Washington: U.S. Department of Commerce. 1995.

Populations for 1993--The population of the United States by age, sex, race and Hispanic origin are tabulated from Census file RESO793. Washington: U.S. Department of Commerce. 1995.

Populations for 1992--The population of the United States by age, sex, race and Hispanic origin are tabulated from census file RESPO792. Washington: U.S. Department of Commerce. 1994.

Populations for 1991--The population of the United States by age, race, and sex are shown in Current Population Reports, Series P-25, Number 1095. Monthly population figures were published in Current Population Reports, Series P-25, Number 1097.

Populations for 1990--The population of the United States by age, race, and sex, and the population for each State are shown in Current Population Reports, Series P-25, Number 1095. The figures have been modified as described above. Monthly population figures were published in Current Population Reports, Series P-25, Number 1094.

Population estimates for 1981-89--Birth rates for 1981-89 (except those for cohorts of women) have been revised, based on revised population estimates that are consistent with the 1990 census levels, and thus may differ from rates published in volumes of Vital Statistics of the United States for these years. The 1990 census counted approximately 1.5 million fewer persons than had earlier been estimated for April 1, 1990. The revised estimates for the United States by age, race, and sex were published by the U.S. Bureau of the Census in Current Population Reports, Series P-25, Number 1095. Population estimates by month are based on data published in Current Population Reports,

Series P-25, Number 1094 and unpublished data. Unpublished revised estimates for States were obtained from the U.S. Bureau of the Census.

Populations for 1980—The population of the United States by age, race, and sex, and the population for each State are shown in tables 4-2 and 4-3 of volume I, Vital Statistics of the United States, 1980. The figures by race have been modified as described above. Monthly population figures were published in Current Population Reports, Series P-25, Number 899.

Population estimates for 1971-79—Birth rates for 1971-79 (except those for cohorts of women) have been revised, based on revised population estimates that are consistent with the 1980 census levels, and thus may differ from rates published in volumes of Vital Statistics of the United States for these years. The 1980 census counted approximately 5.5 million more persons than had earlier been estimated for April 1, 1980 (17). The revised estimates for the United States by age, race, and sex were published by the U.S. Bureau of the Census in Current Population Reports, Series P-25, Number 917. Population estimates by month are based on data published in Current Population Reports, Series P-25, Number 899. Unpublished revised estimates for States were obtained from the U.S. Bureau of the Census.

Population estimates for 1961-69—Birth rates for 1961-69 are based on revised estimates of the population and thus may differ slightly from rates published before 1976. The revised estimates used in computing these rates were published in Current Population Reports, Series P-25, Number 519. The rates for 1961-64 are based on revised estimates of the population published in Current

Population Reports, Series P-25, Numbers 321 and 324 and may differ slightly from rates published in those years.

Population estimates for 1951-59--Final intercensal estimates of the population by age, race, and sex and total population by State for 1951-59 are shown in tables 4-4 and 4-5 of volume I, Vital Statistics of the United States, 1966. Beginning with 1963 these final estimates have been used to compute birth rates for 1951-59 in all issues of Vital Statistics of the United States.

Net census undercounts and overcounts

The U.S. Bureau of the Census has conducted extensive research to evaluate the coverage of the U.S. population (including undercount, overcount, and misstatement of age, race, and sex) in the last five decennial censuses 1950, 1960, 1970, 1980, and 1990. These studies provide estimates of the national population, that were not enumerated or overenumerated in the respective censuses, by age, race, and sex (17-19). The report for 1990 (20) includes estimates of net underenumeration and overenumeration for age, sex, and racial subgroups of the national population, modified for race consistency with previous population counts as described in the section "Population bases."

These studies indicate that there are differential coverages in the censuses among the population subgroups; that is, some age, race, and sex groups are more completely enumerated than others. To the extent that these estimates of overcounts or undercounts are valid, that they are substantial, and that they vary among subgroups and geographic areas, census miscounts can have consequences for vital statistics measures (18). However, the effects of undercounts in the census are reduced to the extent that there is underregistration of births. If these two factors are of equal

magnitude, rates based on unadjusted populations are more accurate than those based on adjusted populations because the births have not been adjusted for underregistration.

The impact of net census miscounts on vital statistics measures includes the effects on levels of the rates and effects on differentials among groups.

If adjustments were made for persons who were not counted in the census of population, the size of the denominators would generally increase and the rates would be smaller than without an adjustment. Adjusted rates for 1990 can be computed by multiplying the reported rates by ratios of the 1990 census-level population adjusted for the estimated net census miscounts, which are shown in table C. A ratio of less than 1.0 indicates a net census undercount and would result in a corresponding decrease in the rate. A ratio in excess of 1.0 indicates a net census overcount and would result in a corresponding increase in the rate.

Enumeration of white females in the childbearing ages was at least 97 percent complete for all ages. Among black women, the undercount ranged up to 5 percent. Generally, females in the childbearing ages were more completely enumerated than males for similar race-age groups.

If vital statistics measures were calculated with adjustments for net census miscounts for each of these subgroups, the resulting rates would have been differentially changed from their original levels; that is, rates for those groups with the greatest estimated overcounts or undercounts would show the greatest relative changes due to these adjustments. Thus the racial differential in fertility between the white and the "All other" population can be affected by such adjustments.

Cohort fertility tables

The various fertility measures shown for cohorts of women are computed from births adjusted

for underregistration and population estimates corrected for underenumeration and misstatement of age. Data published after 1974 use revised population estimates prepared by the U.S. Bureau of the Census and have been expanded to include data for the two major racial groups. Heuser has prepared a detailed description of the methods used in deriving these measures as well as more detailed data for earlier years (21).

Parity distribution—The percent distribution of women by parity (number of children ever born alive to mother) is derived from cumulative birth rates by order of birth. The percent of zero-parity women is found by subtracting the cumulative first birth rate from 1,000 and dividing by 10. The proportions of women at parities one through six are found from the following formula:

$$\text{Percent at N parity} = (\text{cum. rate, order N}) - (\text{cum. rate, order N} + 1)10$$

The percent of women at seventh higher parities is found by dividing the cumulative rate for seventh-order births by 10.

Birth probabilities—birth probabilities indicate the likelihood that a woman of a certain parity and age at the beginning of the year will have a child during the year. Birth probabilities differ from central birth rates in that the denominator for birth probabilities is specific for parity as well as for age.

Age-sex-adjusted birth rates

The age-sex-adjusted birth rates are computed by the direct method. The age distribution of women aged 10-49 years as enumerated in 1940 and the total population of the United States for that year are used as the standard populations. The age-sex-adjusted birth rates show differences in the level of fertility independent of differences in the age and sex composition of the population. It is important not to confuse these adjusted rates with the crude rates shown in other tables.

Total fertility rate

The total fertility rate is the sum of the birth rates by age of mother (in 5-year age groups) multiplied by 5. It is an age-adjusted rate because it is based on the assumption that there are the same number of women in each age group. The rate of 2,036 in 1994, for example, means that if a hypothetical group of 1,000 women were to have the same birth rates in each age group that were observed in the actual childbearing population in 1994, they would have a total of 2,036 children by the time they reached the end of the reproductive period (taken here to be age 50 years), assuming that all of the women survived to that age.

Intrinsic vital rates

The intrinsic vital rates are calculated from a stable population. A stable population is that hypothetical population, closed to external migration, that would become fixed in age-sex structure after repeated applications of a constant set of age-sex specific birth and death rates. For the mathematical derivation of intrinsic vital rates, see pages 4-13 and 4-14 in the Technical Appendix of volume I, Vital Statistics of the United States, 1962. The technique of calculating intrinsic vital rates is described by Barclay (22).

Seasonal adjustment of rates

The seasonally adjusted birth and fertility rates are computed from the X-11 variant of Census Method II (23). This method of seasonal adjustment used since 1964 differs slightly from the U.S. Bureau of Labor Statistics (BLS) Seasonal Factor Method, which was used for Vital Statistics of the United States, 1964. The fundamental technique is the same in that it is an adaptation of the ratio-to-moving-average method. Before 1964 the method of seasonal adjustment was based on the X-9 variant and other variants of Census Method II. A comparison of the Census Method II with the BLS Seasonal Factor Method shows the differences in the seasonal patterns of births to be negligible.

Computation of percents, medians, and means

Percent distributions, medians, and means are computed using only events for which the characteristic is reported. The "Not stated" category is subtracted from the total before computation of these measures. The asterisk (*) indicates that the numerator and/or denominator number is less than 20.

Monthly Vital Statistics Report

Final Data From the CENTERS FOR DISEASE CONTROL AND PREVENTION/National Center for Health Statistics

Report of Final Natality Statistics, 1995

Stephanie J. Ventura, A.M.; Joyce A. Martin, M.P.H.; Sally C. Curtin, M.A.;
and T. J. Mathews, M.S., Division of Vital Statistics

Abstract

Objectives—This report presents 1995 data on U.S. births according to a wide variety of characteristics. Data are presented for maternal demographic characteristics including age, live-birth order, race, Hispanic origin, marital status, and educational attainment; maternal lifestyle and health characteristics (medical risk factors, weight gain, and tobacco and alcohol use); medical care utilization by pregnant women (prenatal care, obstetric procedures, complications of labor and/or delivery, attendant at birth, and method of delivery); and infant health characteristics (period of gestation, birthweight, Apgar score, abnormal conditions, congenital anomalies, and multiple births). Also presented are birth and fertility rates by age, live-birth order, race, Hispanic origin, and marital status. Selected data by mother's State of residence are shown, as well as data on month and day of birth, sex ratio, and age of father. Trends in fertility patterns and maternal and infant characteristics are described and interpreted.

Methods—Descriptive tabulations of data reported on the birth certificates of the 3.9 million births that occurred in 1995 are presented.

Results—Birth and fertility rates generally declined in 1995. Birth rates for teenagers fell 3 to 4 percent, with larger reductions reported for black teenagers. Rates for women in their twenties declined slightly while rates for women in their thirties rose modestly. The number and rate of births to unmarried women declined in 1995; however, about two-thirds of the decline in the number is due to changes in the reporting of marital status in California. Smoking by pregnant women dropped again and improvements in prenatal care utilization continued. The cesarean delivery rate declined. Key measures of birth outcome, however—the percents of low birthweight and preterm births—were unchanged. The proportions of multiple births, especially triplets, continued to rise.

Keywords: birth certificate • maternal and infant health • birth rates • maternal characteristics

Highlights

Births in the United States declined in 1995 for the fifth consecutive year, to 3,899,589. The 1995 total is 1 percent lower than in 1994 (3,952,767), and 6 percent below the 1990 total (4,158,212), the most recent high point. The **birth rate** dropped 3 percent in 1995, 14.8 births per 1,000 total population; this rate has dropped 11 percent during the 1990–95 period. The **fertility rate** declined 2 percent to 65.6 births per 1,000 women aged 15–44 years. This rate fell 7 percent from 1990 (70.9 per 1,000) to 1995.

Birth rates for teenagers declined 3 to 4 percent in 1995, to 36.0 per 1,000 women aged 15–17 years and 89.1 per 1,000 women aged 18–19 years. The overall rate for teenagers was 56.8 per 1,000, 4 percent lower than in 1994 (58.9). While declines were observed for all racial and Hispanic origin groups, the largest decline—8 percent overall—was reported for black teenagers. Birth rates for all teenagers declined 6 to 7 percent during the 1990's. Recent declines in abortion rates combined with these reductions in birth rates for teenagers indicate that the

Acknowledgments

This report was prepared under the general direction of Kenneth G. Keppel, Acting Chief of the Reproductive Statistics Branch. Nicholas F. Pace, Chief of the Systems, Programming, and Statistical Resources Branch (SPSRB), and Manju Sharma, Jordan Sacks, and Gail Parr of SPSRB provided computer programming support and statistical tables. Thomas D. Dunn of SPSRB provided content review. Staff of the Data Acquisition and Evaluation Branch carried out quality evaluation and acceptance procedures for the State data files on which this report is based. The Registration Methods staff of the Division of Vital Statistics consulted with State vital statistics offices regarding the collection of birth certificate data. This report was edited by Demarius V. Miller and typeset by Jacqueline M. Davis of the Publications Branch, Division of Data Services.

U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES
Centers for Disease Control and Prevention
National Center for Health Statistics

teenage pregnancy rate has continued to fall in the 1990's.

Birth rates for women in their twenties declined 1 percent each for ages 20–24 years (to 109.8 per 1,000) and 25–29 years (112.2). Each of these rates in 1995 was lower than for any year since 1987; rates for women in their twenties declined 6 to 7 percent during the period 1990–95.

Birth rates for women in their thirties rose 1 percent for ages 30–34 years (to 82.5) and 2 percent for ages 35–39 years (to 34.3). The pace of increase in these rates, which had jumped 54–67 percent during the 1980's, has slowed considerably during the 1990's.

Birth rates for women in racial and Hispanic origin populations differ substantially. Rates continue to be highest for Hispanic women (especially Mexican American women) and black women. Rates are successively lower for American Indian, Asian or Pacific Islander, and non-Hispanic white women. Rates for teenagers were highest for Mexican American, Puerto Rican, and black women. Rates for women in their thirties were highest for Asian or Pacific Islander and non-Hispanic white women. Fertility rates for women in most racial and Hispanic origin groups declined in 1995.

The birth rate for unmarried women declined 4 percent in 1995 to 45.1 births per 1,000 unmarried women aged 15–44 years (compared with 46.9 in 1994). The procedures for determining the mother's marital status changed significantly in California for Hispanic-origin births and in Nevada for all births in 1995. While it is not possible to quantify the impact of these changes for all groups, birth rates for non-Hispanic white women and black women were essentially unaffected. The rate for non-Hispanic white women declined 1 percent and the rate for black women fell 8 percent.

Cigarette smoking during pregnancy declined in 1995 to 13.9 percent of women giving birth. Tobacco use during pregnancy has declined steadily since 1989. Smoking rates fell for women in most racial and Hispanic origin populations, with rates for Hispanic women and women in most Asian or Pacific Islander populations substantially lower (3 to 4

percent on average) than for other groups. Maternal smoking has a strong adverse effect on infant birthweight. In 1995, 12.2 percent of infants born to smokers weighed less than 2,500 grams (5 lb 8 oz), compared with 6.8 percent of births to nonsmokers.

The percent of mothers who began **prenatal care** within the first trimester of pregnancy improved to 81.3 percent for 1995, and the proportion of mothers with late or no care dropped to 4.2 percent. Timely care has been on the rise throughout the 1990's, rising from 75.8 percent in 1990. Levels of first trimester care increased between 1994 and 1995 among white (83.6 percent), black (70.4 percent), and Hispanic mothers (70.8 percent).

The rate for the most prevalent **obstetric procedure**, electronic fetal monitoring, rose for the sixth consecutive year to include 81 percent of all births. The use of ultrasound was the same as in 1994 (61 percent). Although less common than the former two procedures, the rates for induction of labor and stimulation of labor have been rising steadily every year since they were first reported on the birth certificate in 1989.

Data on **method of delivery** show that the rate of cesarean delivery declined for the sixth consecutive year and was 9 percent lower in 1995 (20.8 percent) than in 1989 (22.8 percent). The primary cesarean rate was also 9 percent lower in 1995 (14.7 first cesareans per 100 women who had no previous cesarean) than in 1989 (16.1). The rate of vaginal birth following a previous cesarean delivery (VBAC) was 46 percent higher in 1995 (27.5) than in 1989 (18.9). Overall cesarean rates increase steadily with advancing age of mother and were more than twice as high for mothers 40–49 years of age (31.6) than for teenagers (14.7). The percent of births delivered by forceps continued to decline (3.5 percent in 1995) while the use of vacuum extraction rose (5.9 percent in 1995).

The rate of **preterm birth** (less than 37 completed weeks of gestation) was unchanged at 11.0 percent. This proportion has risen 17 percent (from 9.4 percent) since 1981. Preterm births increased among white mothers (9.6 to 9.7 percent), but declined among black mothers to the

lowest level reported since the mid 1980's (17.7 percent).

The percent **low birthweight** was 7.3 for 1995, the same level reported for 1994—the highest reported since 1976. Low birthweight (less than 2,500 grams) increased among white mothers from 6.1 to 6.2 percent. Low birthweight among white births has increased since 1990 from 5.7 percent. Among births to black mothers, low birthweight declined from 13.2 to 13.1 percent for 1994–95, continuing a downward trend observed since 1992.

The number of twin births declined very slightly for 1995 to 96,736 births, but the number of triplet and other higher order multiple births rose by 8 percent, to 4,973 births. As a result, the **multiple birth ratio** rose to 26.1 per 1,000 live births and the triplet and other higher order multiple birth ratio rose 10 percent to 127.5 per 100,000, double the ratio reported for 1989 (69.2).

Introduction

This report, the annual release of national birth statistics, presents detailed data on births, birth and fertility rates, maternal lifestyle and health characteristics, medical services utilization by pregnant women, and infant health characteristics. These data provide important information on fertility patterns among American women by such characteristics as age, live-birth order, race, Hispanic origin, marital status, and educational attainment. Up-to-date information on these fertility patterns is critical to understanding population growth and change in this country and in individual States. Data on maternal characteristics affecting birth outcome such as weight gain, tobacco and alcohol use, and medical risk factors are useful in accounting for differences in birth outcome. Information on use of prenatal care, obstetric procedures, complications of labor and/or delivery, attendant at birth and place of delivery, and method of delivery by maternal demographic characteristics can also help to explain differences in birth outcomes. It is very important that data on birth outcomes, especially levels of low birthweight and preterm birth, be continuously monitored, because these variables are

important predictors of infant mortality and morbidity. Reports presenting information on maternal and infant characteristics available since the birth certificate was revised in 1989 have been published (1-9).

A report of preliminary birth statistics for 1995 presented data on selected topics based on a substantial sample (about 90 percent) of the 1995 birth file (10). The selected measures included birth rates by age, race, and Hispanic origin of mother, and by live-birth order, and summary national and State data on marital status, prenatal care, cesarean delivery, and low birthweight. Findings based on the complete file in this report are essentially identical with data based on the preliminary series, thus validating the preliminary statistics.

Methods

Data shown in this report are based on 100 percent of the birth certificates registered in all States and the District of Columbia. More than 99 percent of births occurring in this country are registered (11). Tables showing data by State also provide separate information for Puerto Rico, Virgin Islands, and Guam. In this report, tabulations of births beginning with 1980 data are by race of mother; for years prior to 1980, tabulations are by race of child. Details of the differences in tabulation procedure are described in the Technical notes. Race and ethnicity differentials in birth rates and characteristics of births may reflect differences in income, educational levels, access to health care, and health insurance. Text references to black births and black mothers or white births and white mothers are used interchangeably. Additional information on the measurement of marital status, gestational age, and birthweight; the computation of derived statistics and rates; population denominators; random variation and relative standard error; and the definitions of terms are presented in the Technical notes.

Results and discussion

Demographic characteristics

Births and birth rates

Births in the United States continued to decline in 1995, to 3,899,589, 1 percent

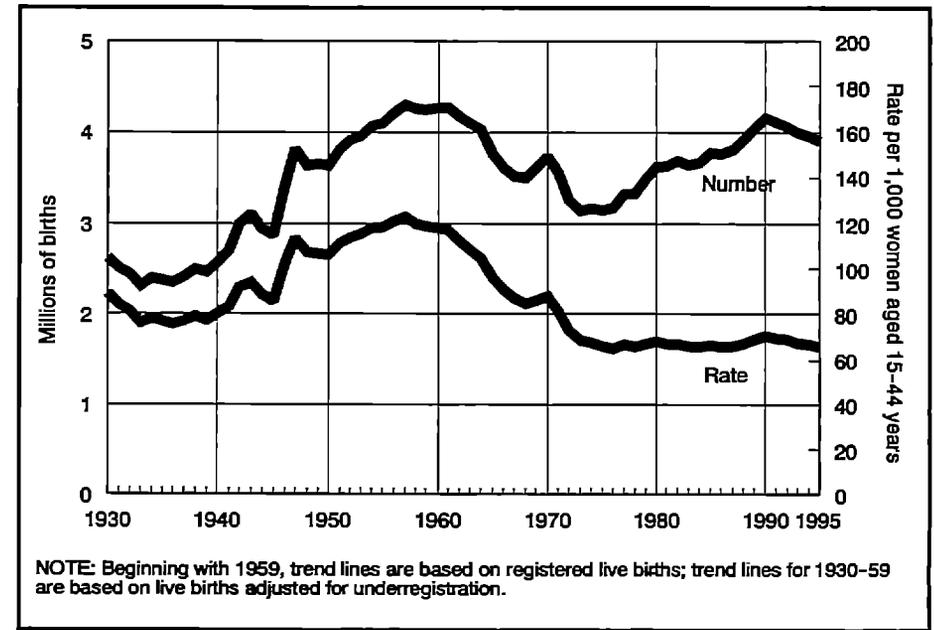

Figure 1. Live births and fertility rates: United States, 1930-95

fewer than in 1994. U.S. births dropped 6 percent between 1990, the recent high point (4,158,212), and 1995 (table 1 and figure 1). The 1995 total is lower than in any year since 1987. Provisional data for the first 11 months of 1996 suggest a slight increase in the number. Births declined about 1 percent per year from 1990 to 1995, following increases of about 3 percent per year between 1986 and 1990.

The birth rate in 1995 was 14.8 live births per 1,000 population, 3 percent lower than in 1994 (15.2). The 1995 rate is the lowest recorded in nearly two decades (14.6 in 1976). The U.S. birth rate dropped 11 percent between 1990 and 1995, about 2 percent per year, following a 2 percent annual increase during 1986-90. According to provisional data for January-November 1996, the birth rate declined slightly.

The fertility rate, which relates births to the number of women in the childbearing ages, was 65.6 live births per 1,000 women aged 15-44 years in 1995, 2 percent below the 1994 level. This rate fell 7 percent between 1990 and 1995, following an 8 percent rise during 1986-90. The fertility rate for 1995 was lower than for any year since 1986 (65.4). Provisional data for January-November 1996 indicate essentially no change compared with 1995.

Age of mother—Birth rates by age of mother fell 1 to 4 percent for women

aged 15-29 years, and rose by 1 to 3 percent for women in age groups 30-44 years. The rate for women aged 45-49 years did not change. (See tables 2-7 and figure 2 for births and birth rates by age of mother, live-birth order, race, and Hispanic origin.)

The birth rate for young teenagers 10-14 years declined from 1.4 to 1.3 per 1,000, the first reduction for this age group since 1980. During the years 1980-94, the rate rose very slowly from 1.1 to 1.4 per 1,000.

The rate for teenagers 15-19 years fell 4 percent to 56.8 per 1,000. This rate declined steadily by 9 percent from its recent high in 1991 (62.1) to 1995. Despite the recent declines, the rate for 1995 is still considerably higher than it was during the early to mid-1980's (50-53 per 1,000) (table 4). The increases beginning in the late 1980's were substantial—24 percent from 1986 to 1991. According to a recent report, teenage birth rates for most States declined in the 1990's, concurrent with the decline in the U.S. rate (12).

Birth rates for teenage subgroups 15-17 and 18-19 years also dropped between 1994 and 1995. The rate for teenagers 15-17 years fell 4 percent, from 37.6 to 36.0 per 1,000. Between 1991 and 1995, this rate fell by 7 percent. However, the rate for 1995 was still higher than during the period 1976-88 when it

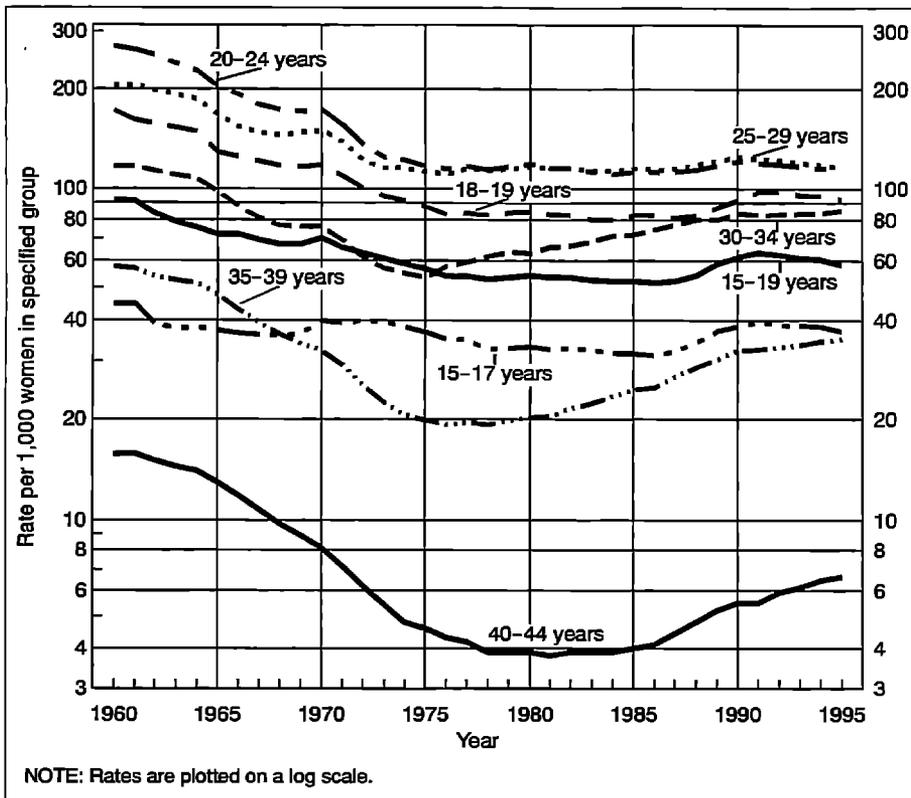

Figure 2. Birth rates by age of mother: United States, 1960–95

ranged from 31 to 34. The number of births to 15–17-year-olds fell 1 percent, to 192,508. This decline resulted from the 4 percent decline in the birth rate which more than compensated for the 3 percent increase in the number of teenagers in this age group (13). In order for the number of births to continue to decline in the next several years, the birth rate will have to continue to decline more than enough to compensate for the projected 7 percent increase in the number of women aged 15–17 between 1995 and 2000 (14).

The birth rate for older teenagers 18–19 years declined 3 percent, from 91.5 to 89.1 per 1,000. During the period 1992–95, this rate fell 6 percent. Still the rate for 1995 was higher than in any year from 1974 to 1990 (table 4). During those years, the rate ranged from 77.4 to 88.7 per 1,000. The number of births to women aged 18–19 years declined 1 percent between 1994 and 1995—to 307,365. During the period 1990–95, the number dropped 9 percent (12). The 1994–95 decline is the result of the 3-percent drop in the birth rate which more than offset the 2-percent increase in the number of women in that age group (13). However,

as is the case for younger teenagers, the number of older teenagers is also projected to grow—by 14 percent between 1995 and 2000 (14). Thus, further declines in the number of births to women aged 18–19 will depend on continued declines in the birth rate that make up for the increased number of women.

Birth rates for women aged 20–24 and 25–29 years—the principal childbearing ages—fell by 1 percent each in 1995, to 109.8 and 112.2 per 1,000, respectively. Each of these rates in 1995 was lower than in any year since 1987. Birth rates for women in their twenties dropped 6 to 7 percent between 1990 and 1995. Except for a brief spurt in the late 1980's when these rates rose 8 to 9 percent, rates for women in their twenties were relatively stable from the mid-1970's to the early 1990's.

Birth rates for women aged 30 years and over have been the only ones for which sustained substantial increases have been measured since the late 1970's. However, the pace of increase in these rates slowed considerably during the 1990's. The birth rate for women aged 30–34 years increased 1 percent in 1995, to 82.5 per 1,000. Between 1990 and 1995, this

rate rose just 2 percent, following a 15-year period of substantial steady increase of 54 percent (from 52.3 in 1975 to 80.8 in 1990). Because the rate increased so modestly in 1995 and the number of women aged 30–34 fell 1 percent, the number of births in this age group fell slightly. The number of women aged 30–34 years is projected to decline further in the next few years—by 11 percent between 1995 and 2000 (14). Therefore, without a larger increase in the birth rate, the number of births will likely decline further.

The birth rate for women aged 35–39 years rose 2 percent—from 33.7 to 34.3 per 1,000. The pace of increase in this rate has also slowed markedly in the 1990's—just 8 percent between 1990 and 1995, following a 67-percent rise from 1978 (19.0) to 1990 (31.7). Because the birth rate rose 2 percent and the number of women aged 35–39 increased 1 percent, the number of births in this age group rose 3 percent in 1995 to a record high 383,745.

The birth rate for women in their early forties increased 3 percent in 1995, to 6.6 per 1,000 women aged 40–44 years. This rate rose 20 percent between 1990 (5.5) and 1995, and increased 74 percent during 1981–95. The number of women aged 40–44 years continued to rise—by 3 percent (13,15). Increases in the birth rate and the number of women combined to produce a 6-percent rise in the number of births—to 67,250, more than in any year since 1966.

The declines in birth rates for teenagers since 1991 likely reflect a combination of demographic and behavioral factors. According to the 1995 National Survey of Family Growth (NSFG), the proportion of teenagers who are sexually experienced has stabilized and declined compared with the 1988 NSFG. Furthermore, those teenagers who are sexually active are now more likely to be using contraceptives (16).

Teenage pregnancy rates have also declined in recent years. That is, the recent declines in the teenage birth rate have been accompanied by declines in the abortion rate (17). The pregnancy rate for 15–19-year-olds fell 3 percent from 1991 (115 per 1,000) to 1992 (111), following a 10-percent rise between 1986

and 1990–91 (9,18). Further declines in the teenage pregnancy rate since 1992 are indicated by the steady decline in the teen birth rate and declines in abortions among teenagers, according to preliminary data (17,19).

The accelerated pace of increase in birth rates for women aged 30 years and over observed from the mid- to late-1970's until 1990 has slowed markedly in the 1990's, especially for women aged 30–34 years (table 4) (20). Changes in a number of factors have contributed to this moderation. One is the stabilization in the proportion of women in their early thirties who are childless. This proportion approximately doubled between the early 1970's (21) and 1990, but has remained at 20 percent since. Moreover, the proportions of currently married childless women who report that they expect to have a child fell in the 1990's, probably a reflection of changing perceptions as to whether their expectations can be realized (22). About 40 percent of currently childless women aged 35–44 years have impaired fertility according to the 1995 NSFG (16). This fact may explain the recent changes in birth expectations and birth rates.

Live-birth order—The first birth rate fell 1 percent in 1995, to 27.3 first births per 1,000 women aged 15–44 years, the lowest level reported since 1987. This rate fell 6 percent between 1990 (29.0) and 1995. Rates for second and third order births fell 2 percent between 1994 and 1995, while the rate for fourth births declined 5 percent. Rates also declined for fifth and sixth-seventh order births and did not change for eighth and higher order births.

First birth rates declined for women in age groups 15–24 years, and rose for women in age groups 25–44 years. The first birth rate for teenagers 15–17 years declined 4 percent, while the rate for older teenagers declined 1 percent. Changes in first birth rates for women in their twenties were 1 percent or less. Rates for women aged 30–34 and 35–39 years each rose 3 percent. Consistent with these changes by age in first birth rates and changes in the number of women by age, the proportion of first births occurring to women aged 30 years and over rose to a

record 22 percent in 1995, compared with 5 percent in 1975 (20).

Birth rates for second births for teenagers declined in 1995, by 4 to 9 percent. Rates for second and third order births declined 1 to 3 percent for women in their twenties, while rates for fourth and fifth order births dropped 4 to 8 percent. Rates for second and third order births for women in their thirties rose modestly. Higher order birth rates for women in their thirties declined up to 6 percent or were unchanged. There was no change in these rates for women in their forties.

Race—The number of births declined 1 percent each for white and American Indian mothers, and 5 percent for black mothers. A 2-percent increase was recorded for Asian or Pacific Islander (API) mothers. Fertility rates for white and API women declined 1 percent each to 64.4 and 66.4, respectively. The rate for black women declined 6 percent to 72.3, and the rate for American Indian women dropped to 69.1. The range in these rates in 1995 was the smallest measured since 1980, when rates for API and American Indian women first became available. The highest rate in 1995 (for black women) was only 12 percent greater than the lowest rate (white women). (See tables 1–9 for national and State data.)

Between 1990 and 1995, fertility rates by race declined 5 to 6 percent for white and API women, 9 percent for American Indian women, and 17 percent for black women. Parallel reductions were also observed in the numbers of births in each of these groups, except for API women, among whom there was a 13-percent increase in births. The number of API births rose sharply during this period because the number of API women in the childbearing ages increased 19 percent (13).

There is a distinctive pattern in age-specific birth rates by race. In the teenage years, rates for black and American Indian women are substantially higher than for white and API women; the disparity is greatest for younger teenagers 10–14 and 15–17 years. For example, among teenagers 15–17 years, rates in 1995 for American Indian and black teenagers (48–70 per 1,000) were 59–353 percent higher than the rates for API and white teenagers

of the same age (15–30 per 1,000). Rates by race converge most at ages 25–29 years, with a range of 98–115 per 1,000. With advancing maternal age, the patterns of rates shift, so that rates begin to be highest for white and API women.

Although birth rates for black teenagers continue to be higher than for other racial groups, in recent years, these rates have fallen more sharply than for any other group. During the period 1991–95, the rate for black women aged 15–19 years dropped 17 percent; declines for teenage subgroups 15–17 and 18–19 years were 17 and 14 percent, respectively. Birth rates for black teenagers in 1995 were lower than in nearly a decade (table 4).

It is evident that the high birth rates—especially first birth rates—for white and API women in their thirties reflect a pattern of delayed childbearing. First birth rates for API women aged 30–34 and 35–39 years were at least two-thirds higher than for any other group. Additional evidence of this pattern is the dramatically low proportions of births to API teenagers—6 percent on average—compared with 12–23 percent for other racial groups (table 10). Evidence of delayed childbearing for several API subgroups has been reported previously (23,24). Unfortunately, the populations necessary to compute birth rates for specific API subgroups, including those in the “other API” category, are available only in census years.

Hispanic origin—The fertility of Hispanic women as a group decreased 1 percent between 1994 and 1995, from 105.6 to 105.0 per 1,000 women aged 15–44 years. The rate for Mexican American women rose 1 percent (from 115.4 to 117.0), whereas rates for Cuban and “other” Hispanic women declined 1 to 3 percent (from 55.9 to 55.1 and from 97.7 to 94.5, respectively). The rate for Puerto Rican women dropped 8 percent (from 81.9 to 75.7). (See tables 6,7,9, and 11 for births and birth rates.)

Birth rates by age for women 15 years and over were higher for Hispanic women overall and for Mexican American women than for either white or black non-Hispanic women. While birth rates for Mexican American teenagers have been somewhat higher than for black

non-Hispanic teenagers in recent years, in 1995, the rates for Mexican American teenagers were substantially higher—25 percent on average. Birth rates by age for Hispanic and non-Hispanic black teenagers were 2.1 to 3.3 times the rates for non-Hispanic white teenagers in 1995 (table A), continuing a pattern observed for several years. This differential in rates by race and Hispanic origin generally declines with advancing maternal age, but rates in each age group are consistently highest for Hispanic women.

The birth rate for Hispanic teenagers as a group declined 1 percent in 1995 (106.7). However, the trends for Hispanic subgroups differed considerably. Rates for Mexican American teenagers rose 7 percent from 116.2 to 124.6 per 1,000 teenagers 15–19 years, while the rate for Puerto Rican teenagers fell 16 percent (from 106.0 to 89.0). Birth rates for Cuban and “other” Hispanic teenagers also declined. The birth rate for Mexican American teenagers rose 15 percent between 1993 (108.7) and 1995.

In general, birth rates for Mexican American women rose for age groups under 25 years and changed relatively little for women aged 25 years and over. Rates for Puerto Rican women under 30 years of age declined whereas rates for women aged 30 years and over changed little. Rates for Cuban women in their twenties increased while rates for women aged 30 years and over were relatively stable.

Total fertility rate—The total fertility rate (TFR) indicates the number of births that a hypothetical group of 1,000 women

would have if they experienced during their childbearing years the age-specific birth rates observed in a given calendar year. This hypothetical measure shows the potential impact of current fertility levels on completed family size. The TFR is age-adjusted because it is computed from age-specific birth rates; it assumes the same number of women in each age group.

The TFR in 1995 was 2,019.0, 1 percent lower than in 1994, and 3 percent lower than in 1990 (2,081.0). The TFR continued to fall in 1995 because all rates for women under age 30 years declined—ages where rates are highest; the modest increases in rates for women aged 30 years and over could not compensate for this.

In order for a given generation to exactly replace itself, the TFR must be 2,100. The TFR in the United States has been below this “replacement” level since 1971 (2,266.5). Rates for some racial and/or Hispanic origin groups in 1995 were above replacement level, including Mexican American (3,273.5), “other” Hispanic (2,834.0), Puerto Rican (2,245.5), and non-Hispanic black women (2,245.0) (tables 10–11). Conversely, rates for API (1,924.0), Cuban (1,705.5), and non-Hispanic white women (1,786.5) were considerably lower. The rate for American Indian women was near replacement, at 2,033.5. Consistent with the large declines in birth rates for women under age 30, the TFR’s for black and Puerto Rican women declined considerably in 1995, by 5 to 10 percent.

Births by State

Birth data by race and by Hispanic origin for 1995 are in tables 8 and 9 for the 50 States and the District of Columbia, and Puerto Rico, the Virgin Islands, and Guam. The American Indian, Asian or Pacific Islander (API) and Hispanic populations (and Hispanic subgroups) are highly concentrated geographically. Half of American Indian births in the 50 States and the District of Columbia were to residents of just five States (Alaska, Arizona, California, New Mexico, and Oklahoma), whereas more than half of API births were to residents of California, Hawaii, and New York. Similarly, two-thirds of Hispanic births were to California and Texas residents. Births are also highly concentrated geographically for Hispanic subgroups, Mexican American (California and Texas), Puerto Rican (New York, New Jersey, and Florida), and Cuban (Florida).

Births declined up to 5 percent in 36 States, Puerto Rico, and Guam; 8–9 percent in Vermont and the District of Columbia, and by 14 percent in the Virgin Islands. Increases of up to 5 percent were observed in 13 States.

Birth and fertility rates declined up to 6 percent in 44 States and the District of Columbia, and by 8–9 percent in Vermont. The birth rate was unchanged in Arkansas, Idaho, Nevada, and Oregon, and rose 1 percent in Utah; the fertility rate rose by up to 1 percent in these five States. Birth and fertility rates are not available for Puerto Rico, the Virgin Islands, and Guam.

Sex ratio

There were 1,996,355 male live births in 1995 compared with 1,903,234 female live births. These numbers yielded a sex ratio of 1,049 male per 1,000 female live births (tables 10 and 11), similar to the sex ratio in 1994 (1,048) and similar to ratios over the last 50 years. As in previous years, Asian or Pacific Islander mothers had the highest sex ratio (1,069), followed by white mothers (1,052), American Indian mothers (1,040), and black mothers (1,031). The sex ratio for Hispanic mothers was 1,041, intermediate between non-Hispanic white mothers (1,054) and non-Hispanic black mothers (1,031) (table 11).

Table A. Birth rates by age and Hispanic origin of mother, and by race of mother for mothers of non-Hispanic origin: United States, 1995

[Rate per 1,000 women in specified group]

Age of mother	Total	Hispanic ¹	Non-Hispanic	
			White	Black
15–44 years ²	65.6	105.0	57.6	74.5
10–14 years	1.3	2.7	0.4	4.3
15–19 years	56.8	106.7	39.3	99.3
15–17 years	36.0	72.9	22.0	72.1
18–19 years	89.1	157.9	66.1	141.9
20–24 years	109.8	188.5	90.0	141.7
25–29 years	112.2	153.8	106.5	102.0
30–34 years	82.5	95.9	82.0	65.9
35–39 years	34.3	44.9	32.9	29.4
40–44 years	6.6	10.8	5.9	6.1
45–49 years	0.3	0.6	0.3	0.3

¹Persons of Hispanic origin may be of any race.

²Rates computed by relating total births, regardless of age of mother, to women aged 15–44 years.

Month of birth

Monthly birth rates and fertility rates in 11 months of 1995 were below the rates for the same month observed in 1994. The peak months of occurrence of births in 1995 were July and August (table 12). When the seasonal component is removed from the monthly birth and fertility rates, the underlying trends can be observed. Like the 5 previous years, seasonally adjusted birth and fertility rates for the first half of 1995 were, on average, higher than the rates for the second half of the year. The months of July and August and also March had the lowest seasonally adjusted birth rates in 18 years, while November and December showed the lowest rates since 1976.

Day of the week of birth

Since 1980 when these data were first tabulated, there has been a steady decline in births on Saturdays and Sundays, with a concomitant increase in births on weekdays. Variation in the daily pattern of births can be measured by an index of occurrence. The index is defined as the ratio of the average number of births for a particular day of the week to the average daily number of births for the year, multiplied by 100. In 1995 the Sunday index was 75.2, an indication that there were 24.8 percent fewer births on Sundays than the daily average, considered to be 100.0. The Saturday index was 82.7. As in past years, births occurred most frequently on Tuesdays with an index of 111.3 in 1995.

A weekend deficit is apparent for both vaginal and cesarean deliveries, but is far larger for cesarean deliveries, particularly repeat cesareans (table 13). In 1995 the Sunday index for vaginal births was 80.4, compared with 65.9 for primary, and 38.5 for repeat cesareans.

The growing concentration of births on weekdays in the early and mid-1980's had been attributed to the increasing rate of cesarean deliveries because many cesareans are scheduled on weekdays (25). However, in the late 1980's, the cesarean rate stabilized (26), and since 1989 it has declined. The more recent increase in the weekend deficit can be partly explained by the growing proportion of births that are induced, and the fact that labor is

more likely to be induced on weekdays than on weekends. (See section on Obstetric procedures.)

Births to unmarried women

The birth rate for unmarried women in 1995 was 45.1 births per 1,000 unmarried women aged 15–44 years, 4 percent lower than in 1994 (46.9) (tables 14,15). The number of nonmarital births declined 3 percent to 1,253,976 (compared with 1,289,592) and the proportion of all births to unmarried women declined from 32.6 to 32.2 percent. (See table B for data for 1980–95.)

Much of the decline in nonmarital childbearing in 1995 is associated with changes in the reporting of marital status in California, which particularly affected data for Hispanic women; data for non-Hispanic white women and black women were essentially unaffected by these changes. Procedures for identifying the mother's marital status were modified in 1995 to take into account the naming conventions of Hispanic persons in California. Briefly, if the child is given a double surname of the mother's and father's surnames (either entire surnames or portions of the parents' hyphenated surnames), regardless of sequence, and the mother is of Hispanic origin, the mother's marital status is coded as "Married." Changes were also implemented in 1995 in the reporting of marital status for births in Nevada; these changes resulted in a greater number of births being identified as nonmarital. (See Technical notes.) If births for California and Nevada are excluded from the U.S. data, the number of nonmarital births declined 1 percent

between 1994 and 1995, and the proportion of births to unmarried women was unchanged. The impact of the reporting changes on the *birth rates* cannot be quantified because the relevant populations by marital status are not available at the State level.

Nonmarital birth rates declined 2 percent for white women (from 38.3 to 37.5 per 1,000), 6 percent for Hispanic women (from 101.2 to 95.0), and 8 percent for black women (from 82.1 to 75.9). While the rate for black women was 4.5 times the rate for white women in 1980, 15 years later this differential had dropped to 2.0. Despite the decline in 1995, the rate for white women in 1995 was more than double the rate in 1980 (18.1); in contrast the rate for unmarried black women dropped 6 percent in this time period (from 81.1).

Birth rates for unmarried women declined for women in all age groups under age 40 years (figure 3 and table 15). Rates fell 4–5 percent for teenagers and women aged 25–29 years. The rate for women aged 20–24 years declined 3 percent, whereas rates for women in their thirties declined 1–2 percent.

Rates for unmarried white women declined 2 percent for women in most age groups, while rates by age for unmarried black women dropped 7–9 percent for women under age 30 years and 3–5 percent for women in their thirties; the rate for unmarried black women aged 40–44 years increased. Birth rates for unmarried Hispanic women dropped 4–6 percent for women under age 30 years and 7–13 percent for women aged 30–44 years. As noted above, the changes in the reporting

Table B. Number, rate, and percent of births to unmarried women: United States, 1980 and 1985–95

Year	Number	Rate ¹	Percent ²
1995	1,253,976	45.1	32.2
1994	1,289,592	46.9	32.6
1993	1,240,172	45.3	31.0
1992	1,224,876	45.2	30.1
1991	1,213,769	45.2	29.5
1990	1,165,384	43.8	28.0
1989	1,094,169	41.6	27.1
1988	1,005,299	38.5	25.7
1987	933,013	36.0	24.5
1986	878,477	34.2	23.4
1985	828,174	32.8	22.0
1980	665,747	29.4	18.4

²Percent of all births to unmarried women.

NOTE: See text and Technical notes for discussion of changes in data between 1994 and 1995.

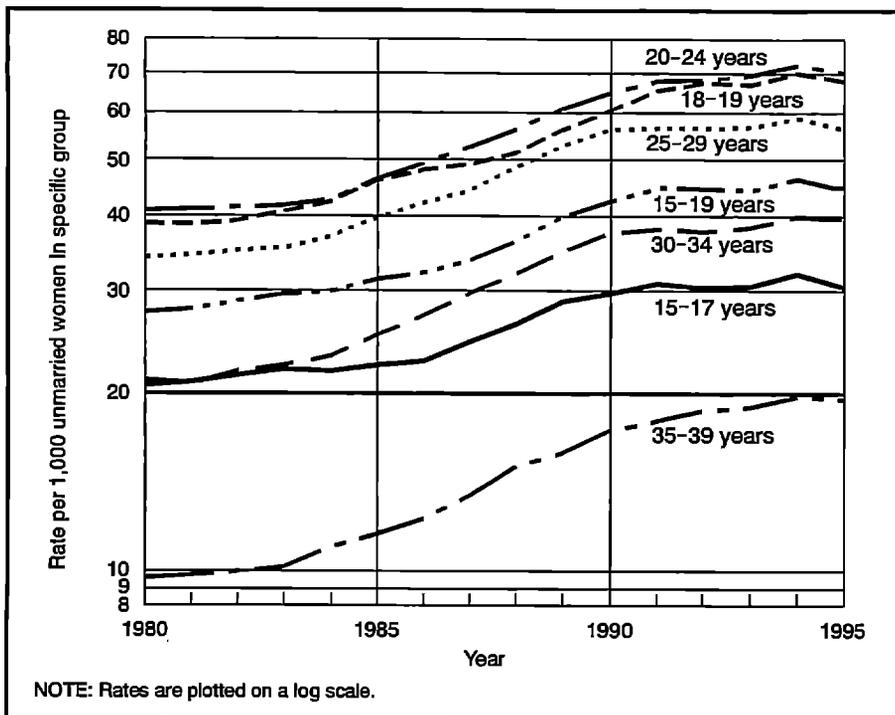

Figure 3. Birth rates for unmarried women, by age of mother: United States, 1980–95

of marital status in California specifically affected Hispanic women; some of the overall decline in the U.S. birth rate for unmarried Hispanic women is a result of the California changes because about 40 percent of U.S. Hispanic births are to California residents.

Birth rates for white women also include births to women of Hispanic origin. Race and Hispanic origin are reported independently on the birth certificate; in 1995 about 91 percent of Hispanic women were reported as white (13). The relatively higher birth rates for Hispanic women thus affect the overall rates and trends for white women. Birth rates for unmarried non-Hispanic white women are available only for 1994 and 1995 because populations for non-Hispanic white women by marital status were not previously available. In general, rates for these women are about 25 percent lower than overall rates for white women in the same age group (table C). Between 1994 and 1995, the birth rate for unmarried non-Hispanic white women declined 1 percent, from 28.5 to 28.2 per 1,000. Rates for non-Hispanic white teenagers declined up to 2 percent. Rates for women in their twenties were unchanged or declined very slightly; increases of up to 2 percent were measured for women in age groups 30 years and over.

Although the overall birth rate for unmarried Hispanic women is 25 percent higher than for black women, this disparity is not observed consistently within age groups. Rates for black teenagers on average were 18 percent higher than for Hispanic teenagers, but the pattern is reversed for women aged 20 years and over, with rates for Hispanic women 17–103 percent higher than for black women. Part of this pattern is linked to the relatively high incidence of cohabitation among Hispanic couples (28). Birth certificate data also provide evidence of this. For example, 43 percent of all births in Puerto Rico were nonmarital in 1995 (table 16), but about three-quarters of these

Table C. Birth rates for unmarried women by age and Hispanic origin and race of mother: United States, 1995

¹Persons of Hispanic origin may be of any race.

²Rates computed by relating all births to unmarried women to unmarried women aged 15–44 years.

³Rates computed by relating all births to unmarried women aged 40 years and over to unmarried women aged 40–44 years.

nonmarital births, or 31 percent of all births, were to mothers living with the father of the child. Increases in cohabitation have been reported in the United States in recent years (29,30).

The proportion of all births to unmarried women declined from 32.6 percent in 1994 to 32.2 percent in 1995. In 1995, 25.3 percent of white births, 69.9 percent of black births, and 40.8 percent of Hispanic births were to unmarried mothers (tables 10, 11, and 14). The proportions of nonmarital births are affected not only by the birth rate for unmarried women and the number of unmarried women, but also by the rate for married women. The rate for married women declined very slightly in 1995, but has fallen sharply in recent years to record low levels. The proportion of births to unmarried women declined in 1995—for the first time in 45 years—because the number of births to unmarried women declined more than the number of births to married women (27). Because the nonmarital birth ratio is affected by marital and nonmarital child-bearing, it has important analytic limitations. However, it is often the only measure that is available in addition to the number of births, because the population data needed to compute rates are not available for States and cities except in census years.

The proportions of nonmarital births vary widely by race and Hispanic origin (tables 10, 11). Thirty-eight percent or more of births to Mexican American, Central and South American, “other” and unknown Hispanic, Hawaiian, American Indian, Puerto Rican, and non-Hispanic black women were nonmarital in 1995. The lowest proportions were reported

for Chinese (8 percent) and Japanese (11 percent) women. The range for other groups was 16–24 percent (“other” Asian or Pacific Islander, Filipino, non-Hispanic white, and Cuban).

Future trends in nonmarital births will be affected demographically by changes both in the number of unmarried women and in their birth rates. Over the next few years, the largest population increases will be among teenagers—most of whom are unmarried—who have accounted for about 30 percent of nonmarital births recently. Rates for teenagers in particular will have to continue to decline as they did in 1995, compensating for the population increase, in order for the overall number of nonmarital births to continue to fall.

The numbers and proportions of births to unmarried women by race are shown in table 16 for the 50 States and the District of Columbia, Puerto Rico, the Virgin Islands, and Guam. The numbers declined in 33 States and the District of Columbia, the Virgin Islands, and Guam, and increased in 17 States and Puerto Rico. The proportions declined in 22 States, the District of Columbia, Virgin Islands, and Guam, and rose in 26 States and Puerto Rico; the proportions were unchanged in Alabama and Utah. The largest changes, as noted above, were in California and Nevada.

Age of father

The birth rate per 1,000 men aged 15–54 years declined for the fifth straight year in 1995, by 2 percent, to 52.0 (table 17). This rate fell by 11 percent between 1990 and 1995, following a 7 percent increase during 1986–90. The procedures for computing birth rates by age of father and the limitations of these data are described in the Technical notes.

The rate for men aged 15–19 years declined by 3 percent from 1994 to 1995. Rates for men in their twenties and for those aged 45–49 years declined by 1 percent. Birth rates for men aged 30–44 years and those aged 50 years and over were generally unchanged.

Birth rates declined by 2 percent for white men, to 49.2 per 1,000, and by 6 percent for black men, to 70.1. Patterns by age for white men showed declines for

ages 15–19, 25–29, and 55 years and over. Birth rates by age for black men declined for all age groups except the oldest, with declines ranging from 3 percent (ages 35–44 years) to 8 percent (ages 15–19 years).

Educational attainment

The educational attainment of women who give birth is important because higher educational attainment is associated with more timely receipt of prenatal care and fewer lifestyle and health behaviors during pregnancy which are detrimental to birth outcome (discussed in later sections). In addition, higher educational attainment has been linked to delayed childbearing and ultimately smaller family sizes (31).

Data from the birth certificate show that the educational attainment of women who gave birth increased substantially over the last few decades, partly reflecting the increases in educational attainment of all women during the time period (32). More than three-fourths of women who gave birth in 1995 had at least 12 years of schooling (77 percent) and 43 percent had at least 1 year of college (table 18). The percent of mothers with at least a high school diploma increased with additional age, to about 90 percent for women who gave birth in their thirties, and then declined slightly for mothers 40 years of age and over (87 percent). The median educational attainment for all mothers in 1995 was 12.8 years.

In general, white mothers had more education than black mothers—78 percent of white mothers had at least a high school diploma compared with 71 percent of black mothers; 45 percent of white mothers had at least some college compared with 32 percent of black mothers. However, the higher educational attainment for white than black mothers was limited to those 25 years of age and over; there was almost no difference by race in educational attainment for teenaged mothers and black mothers 20–24 years of age were slightly more likely to have at least a high school diploma than their white counterparts.

Only two-thirds of American Indian mothers had 12 or more years of schooling, the lowest of any racial group, while 84 percent of Asian or Pacific Islander

mothers had attained this educational level, the highest of any group (table 10). In particular, nearly all of Japanese mothers (97 percent) had 12 or more years of schooling. The proportion of all Hispanic mothers with at least a high school education was low (48 percent) but there was tremendous variation among Hispanic subgroups, ranging from 41 percent of Mexican American mothers to 86 percent of Cuban mothers (table 11). The low educational attainment of Hispanic mothers in general and the variation among subgroups parallels the educational attainment of the Hispanic population in general (33).

Maternal lifestyle and health characteristics

Weight gain

Maternal weight gain is one of the components in the complex relationship between lifestyle characteristics of the mother and the development of the fetus (34). The total weight gained by the mother during pregnancy has been shown to have an independent, positive relationship with the weight of the newborn (35). Inadequate maternal weight gain along with low prepregnancy weight have been shown to be dominant factors in intrauterine growth retardation and low birth-weight (36,37).

In 1990 the National Academy of Sciences published weight-gain guidelines that varied according to mother's body mass index (BMI), which is calculated from her prepregnancy weight and height. The guidelines recommend that women who are underweight (low BMI) gain 28–40 pounds, those who are of normal weight (average BMI) gain 25–35 pounds, those who are overweight (high BMI), gain 15–25 pounds, and obese women, not gain more than 15 pounds (38).

Beginning with 1989, information on maternal weight gain was collected from the birth certificate, but information on the mother's prepregnancy weight and height is not collected. Therefore, it is not possible to determine whether the weight gain was within the recommendations for the mother's BMI. Differences between subgroups in maternal weight gain may reflect differences in the proportion of

mothers who gained outside the recommended range but could also be the result of group differences in height and prepregnancy weight. Given the limitations of vital statistics data, the primary focus of this section is on the median weight gain (for descriptive purposes) and on weight gains that are for most women considered inadequate (less than 16 pounds).

In 1995 all States except California reported information on weight gain. Births to mothers residing in these States accounted for 86 percent of all births in the United States. As in previous years, in 1995 almost two-thirds (64 percent) of women who gave birth gained 26 pounds or more during pregnancy (tables 19–22). The median weight gain was 30.5 pounds in 1995, slightly higher than in 1989 (30.3). The percent of mothers who gained at either end of the weight gain spectrum was higher in 1995 than in 1989—weight gains of less than 16 pounds increased from 9.4 percent in 1989 to 10.7 in 1995, while weight gains of 46 pounds or more increased from 9.1 percent in 1989 to 10.9 percent in 1995.

As expected, the weight gain of the mother varied considerably by period of gestation. Mothers who had preterm infants (gestations of under 37 completed weeks) gained nearly 4 pounds less during pregnancy (27.1 pounds) than mothers who had babies with gestations of 40 weeks and over (30.8 pounds). The percent of mothers who gained less than 16 pounds was almost twice as high for gestations of under 37 weeks than for gestations of 40 weeks and over—17.9 compared with 9.3 percent.

Overall, white women gained 1.6 pounds more during pregnancy than black women—30.6 compared with 29.0 pounds. The disparity in weight gain between white and black women has diminished since 1989 when the median weight gains were 30.5 and 27.8 pounds, respectively. For gestations of under 37 weeks, the median weight gain for white women was 3.3 pounds heavier than for black women but declined to less than a pound for gestations of 40 weeks and over. The percent of black mothers who had weight gains of less than 16 pounds (16.6 percent) was much higher than for white mothers (9.5 percent) while American Indian mothers were intermediate (14.8 percent) (table 23). There was wide

variation among Asian or Pacific Islander (API) subgroups in the percent of mothers who gained less than 16 pounds, ranging from 6.3 percent of Chinese mothers to 11.2 percent of “other” API mothers. These differences in weight gain are at least partially accounted for by the differences among groups in the percent of births born preterm.

The median weight gain for Hispanic mothers (29.8 pounds) was intermediate between non-Hispanic white mothers (30.7 pounds) and non-Hispanic black mothers (29.0 pounds) (table 21). However, the weight gained by Hispanic mothers and non-Hispanic black mothers was the same for gestation periods of 37 weeks or longer. Within Hispanic subgroups, Cuban mothers gained the most weight (31.0 pounds) while Mexican American mothers gained the least (28.8 pounds) and this relationship was evident within each gestational period. The percent of mothers who gained less than 16 pounds was lowest for Cuban mothers (6.9 percent) and highest for Mexican American mothers (13.6 percent) (tables 21 and 24).

As mentioned above, maternal weight gain has been shown to have a positive correlation with the birthweight of the infant. This relationship is substantiated by the data in table 20 which shows the percent of infants with low birthweight by the weight gain of the mother. Overall, the percent of infants with low birthweight drops steadily with increasing weight gain through 45 pounds and then increases slightly for mothers who gained 46 pounds or more. About 15 percent of infants whose mothers gained less than 16 pounds were low birthweight compared with between 4 and 5 percent of mothers who gained 31 pounds or more. The slight increase in low birthweight for mothers who gained 46 pounds or more may be partly attributed to the higher incidence of multiple births among these mothers. More than half of all multiple births are low birthweight (see Multiple births section). The relationship between maternal weight gain and low birthweight was evident for both white and black mothers regardless of gestational period. The general decline in low birthweight up through weight gains of 30 pounds was also present for each Hispanic subgroup (table 22).

Medical risk factors

Medical risk factors can severely complicate pregnancy and result in poor birth outcomes, particularly when not adequately treated. For example, the hypertensive disorders (preeclampsia and pregnancy-associated and chronic hypertension) have been tied to inadequate birthweight, shortened gestations, and infant death; diabetes has been associated with hyaline membrane disease/respiratory distress syndrome, and congenital malformations (39–41).

Sixteen medical risk factors affecting the pregnancy are separately identified on the birth certificate. Although data for this item were missing from only 1.2 percent of records for 1995, birth certificate data may underreport medical risk factor prevalence (42). Also, rates for less common medical risk factors and for smaller population groups can vary widely from year to year and should be used with caution.

Pregnancy-associated hypertension, the most frequently reported risk factor, increased for the fourth consecutive year, rising by 6 percent (from 32.2 to 34.1 per 1,000) between 1994 and 1995. (See table 25 for 1995 data.) The rate of pregnancy-associated hypertension has increased 25 percent since the early 1990's; increases were observed among all age groups. The rate of chronic hypertension was largely unchanged (from 6.8 for 1994 to 6.7 per 1,000 for 1995), and that of eclampsia, a potentially serious hypertensive condition related to pregnancy-associated hypertension, rose slightly from 3.5 to 3.7 per 1,000, but remained lower than the levels reported for 1989–90.

Diabetes and anemia are the second and third most frequently reported maternal medical risk factors. The diabetes rate for the current year was 25.2 compared with 25.5 for 1994. The maternal anemia rate, rose very slightly to 20.5 per 1,000 following a 7 percent rise for 1993–94.

The prevalence of lung disease (e.g., asthma, tuberculosis) and hydramnios/oligohydramnios (the excess or shortage of amniotic fluid) during pregnancy rose by 21 and 12 percent, respectively, between 1994 and 1995. Since 1989 rates for these two medical risk factors have risen steadily and have at least doubled; lung disease has risen from 3.0 to 6.9 and

hydramnios/oligohydramnios from 5.7 to 11.4 per 1,000.

Rates for most medical risk factors vary widely by maternal age. For example, anemia is more common among younger mothers, whereas chronic conditions such as cardiac disease, diabetes, and chronic hypertension occur more frequently among mothers 30 years of age and over. Other risk factors, such as eclampsia and pregnancy-associated hypertension, follow a U-shaped pattern, with rates highest at both ends of the maternal age distribution.

Medical risk factor rates also differ by race or ethnicity. For example, anemia and chronic hypertension are twice as common among black mothers compared with white mothers at nearly each age group. In general, overall trends and differences for 1994–95 in the medical risk factor rates discussed above were applicable for both black and white mothers.

As in previous years, reported levels of anemia, diabetes, and pregnancy-associated hypertension were higher for American Indian mothers than for mothers of any other racial or ethnic group. Each of these risk factors was reported for 4–5 percent of American Indian mothers for 1995 compared with 2–3 percent of mothers overall (table 26).

Medical risk factor rates vary among the Asian or Pacific Islander subgroups. For 1995 the anemia rate for Chinese mothers was the lowest reported of any racial or ethnic groups, and was only about half of the rate for all mothers combined (10.7 compared with 20.5), whereas the anemia rate for Hawaiian mothers (42.4) was among the highest reported for any racial or ethnic group. Diabetes and pregnancy-associated hypertension rates for Asian or Pacific Islander mothers overall were higher than those for all mothers for 1995, but these rates also varied widely among the subgroups.

Levels of maternal anemia and diabetes for Hispanics overall were similar to those for all mothers with some marked variation in rates among subgroups (table 27). The overall Hispanic rate of pregnancy-associated hypertension was 23 percent lower than that for all mothers (26.2 compared with 34.1 per 1,000), and rates were lower than those for all mothers for all subgroups.

Tobacco use during pregnancy

Smoking during pregnancy was reported by 13.9 percent of women giving birth in 1995, down 5 percent compared with 1994 and 29 percent since 1989 (19.5 percent) when this information first became available on the birth certificate (1,9). In 1995 tobacco use was reported on the birth certificate by 46 States, the District of Columbia, and New York City, comprising 80 percent of U.S. births. Information was not available for California, Indiana, South Dakota, and the remainder of New York State. (See tables 28–31 for 1995 data.) Levels of maternal smoking based on the birth certificate are generally consistent with those recently reported from the National Pregnancy and Health Survey (43).

Tobacco use during pregnancy has been associated with a variety of adverse outcomes, including low birthweight, intrauterine growth retardation, infant morbidity, and infant mortality, as well as negative consequences for child health and development (44–47). The mechanisms through which tobacco adversely affects pregnancy and birth outcome have been described elsewhere (48,49).

Maternal smoking declined for women in most racial and Hispanic origin groups (tables 23 and 24). As in previous years, rates were highest for American Indian, non-Hispanic white, and Hawaiian women (16–21 percent), and lowest for Mexican American, Cuban, Central and South American, Chinese, Japanese, Filipino, and “other” Asian or Pacific Islander women, 1–8 percent. Puerto Rican and black women had smoking rates of 10–11 percent. Hispanic and API subgroups are disproportionately underrepresented in the areas reporting tobacco use. However, their generally low smoking rates based on information from birth certificates have been confirmed by other studies (43,50).

Declines in smoking were observed for women aged 20 years and over. Among teenagers 15–19 years, maternal smoking increased about 1 percent overall, but for black teenagers, the rate rose 6 percent, the first such increase since this information first became available in 1989 (1–3, 7–9). Despite this increase, smoking rates for white teenagers are still 4–5 times the rates for black teenagers.

Non-Hispanic white women aged 18–19 years had the highest smoking rate, 29 percent (table 29). Patterns of smoking rates by age differ considerably by race and Hispanic origin (figure 4). At ages under 30 years, rates for non-Hispanic white women are sharply higher than for non-Hispanic black or Hispanic women (table 29). At ages 30 years and over, rates are highest for non-Hispanic black women. Rates for Hispanic women are consistently low, regardless of age, a range of 3–5 percent.

Among smokers, the proportion of women smoking at least half a pack of cigarettes daily has declined steadily in recent years—to 35 percent in 1995 (compared with 42 percent in 1989) (1). White mothers were nearly twice as likely as black mothers to smoke half a pack or more (37 percent compared with 20 percent). The proportion of mothers smoking half a pack or more increases steadily with age for white and black mothers (table 28).

Rates of maternal smoking vary in a distinct pattern according to maternal educational attainment (table 30). Smoking rates are persistently highest for women who have attended but not completed high school, 26 percent in 1995, followed by high school graduates, 18 percent. Rates were lower for women with a grade school education (13 percent) and women with some college (11 percent), with the lowest rate of all reported by college graduates, 3 percent. Even among women aged 20 years and over, smoking rates were highest for mothers who attended but did not graduate from high school (32 percent) (tabular data not shown). Compared with 1994, smoking rates declined for women in all education categories. The pattern of rates was similar for white and black mothers, with rates higher for white than for black women in each education group, except for college graduates.

Babies born to mothers who smoke during pregnancy are at greatly elevated risk of low birthweight (LBW), a finding documented in birth certificate data as well as in numerous other studies (44,48,51). In 1995, 12.2 percent of infants born to smokers weighed less than 2,500 grams (5 lb 8 oz) compared with 6.8 percent of births to nonsmokers (table 31).

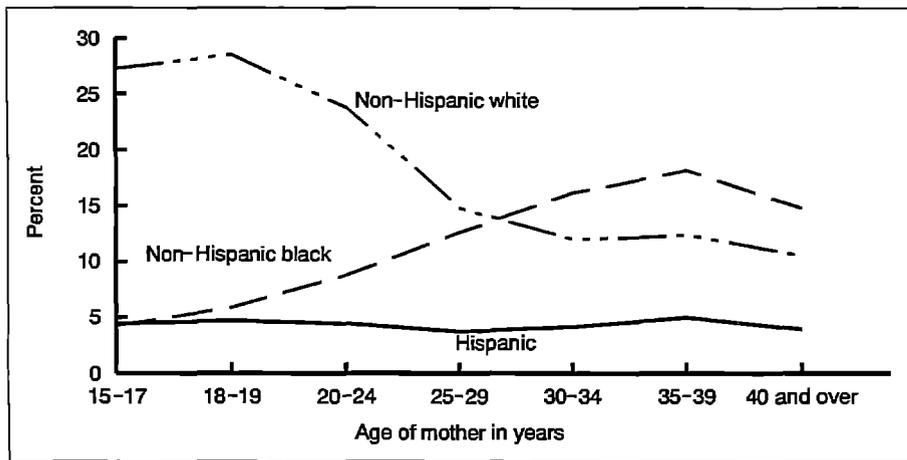

Figure 4. Percent of mothers who smoked during pregnancy by age and race/Hispanic origin of mother: United States, 1995

This nearly twofold differential has been observed since 1989 (1-3, 7-9). The LBW disparity by smoking status is nearly two times for both white and black infants. Advancing maternal age exacerbates the risk; among women aged 30 years and over, the LBW rate for births to smokers was at least 2.3 times that for births to nonsmokers. Some of this pattern is probably related to the much greater cigarette consumption among older women (table 28).

While LBW levels are consistently higher for births to women who smoke, regardless of how many cigarettes smoked, there is a clear pattern of heightened risk as the number of cigarettes increases. Among the lightest smokers (1-5 cigarettes daily), the LBW rate was 11.3 percent, 66 percent higher than for nonsmokers. For mothers smoking more than a pack per day, the rate of LBW was 14.9 percent, one-third higher than that for light smokers and more than double the rate for nonsmokers (6.8 percent) (tabular data not shown).

Alcohol use during pregnancy

Pregnancy and birth outcome can be jeopardized by maternal alcohol use during pregnancy. The most severe adverse effect of excessive drinking is fetal alcohol syndrome, which is characterized by growth retardation, facial malformations, and disorders of the central nervous system associated with mental retardation (52,53). Even low to moderate alcohol use has been shown to negatively impact birth outcome, independent of other risk

factors such as tobacco use and other maternal risk factors (52,54,55).

Reported alcohol use declined again in 1995. Just 1.5 percent of mothers reported any alcohol use compared with 1.7 percent in 1994 and 4.1 percent in 1989, the first year this information was reported on the birth certificates (1,9). All States except California and South Dakota included items on alcohol use on their birth certificates in 1995. This reporting area accounted for 86 percent of U.S. births.

Alcohol use during pregnancy is clearly substantially underreported on the birth certificate (42). A recent study reported that about 19 percent of women used alcohol during pregnancy (43). It is probable that the questions on alcohol use on the birth certificate have unintentionally affected the levels of reporting. These questions focus on the number of drinks per week, while other studies inquire about drinks per month. Women who drink relatively little, perhaps 1 to 2 drinks per month, may believe that their alcohol consumption is too little to report in response to the birth certificate questions. Also contributing to the underreporting, no doubt, is the stigma associated with alcohol use during pregnancy (34, 56).

Even taking into account the severe underreporting of alcohol use on the birth certificate, these data do show a distinct pattern of elevated risk of low birthweight among births to mothers reporting alcohol use. Moreover, greater alcohol consumption is associated with higher low birthweight rates. In 1995, 14.7

percent of births to drinkers weighed less than 2,500 grams, compared with 7.4 percent of births to nondrinkers. The low birthweight rate for births to mothers consuming five drinks or more weekly was more than double the rate for births to mothers consuming one drink or less (25 percent compared with 11 percent) (tabular data not shown).

Medical services utilization

Prenatal care

Prenatal care utilization, as measured by the proportion of mothers beginning prenatal care in the first trimester of pregnancy, improved again for 1995 rising to 81.3 percent from 80.2 percent for 1994. Following rapid improvement during the 1970's, this measure was static for the 1980's, but has risen 8 percent since 1989. (See text table D, figure 5, and table 33.) Concurrent with the 1994-95 rise in timely care, the proportion of mothers who delayed care until the third trimester, or had no care at all, declined slightly from 4.4 to 4.2 percent. The percent of mothers with late or no care has been dropping since 1989 (6.4 percent).

The effects of prenatal care are difficult to measure (57,58), but early, comprehensive care can promote healthier pregnancies by detecting and managing preexisting medical conditions, providing health behavior advice, and assessing the risk of pregnancy complications such as low birthweight and preterm birth (59). Prenatal care can be vital to maternal health and can serve as a gateway into the health care system, especially for socially disadvantaged women (58).

The percent of white mothers receiving first trimester care increased from 82.8 to 83.6 percent between 1994 and 1995, and the proportion of women with late or no care was down very slightly from 3.6 to 3.5 percent. Improvements in first trimester care were observed among all age groups with the largest gains observed for younger mothers.

Among black mothers, first trimester care rose from 68.3 to 70.4 percent, and delayed or no care was down from 8.2 to 7.6 percent between 1994 and 1995. Timely care among black mothers had deteriorated slightly during the 1980's (60), but has risen 17 percent (from 60.0 percent) since 1989.

Table D. First trimester prenatal care by race of mother: United States, 1980 and 1985–95

Year	All races ¹	White	Black
1995	81.3	83.6	70.4
1994	80.2	82.8	68.3
1993	78.9	81.8	66.0
1992	77.7	80.8	63.9
1991	76.2	79.5	61.9
1990	75.8	79.2	60.6
1989	75.5	78.9	60.0
1988	75.9	79.3	60.7
1987	76.0	79.3	60.8
1986	75.9	79.1	61.2
1985	76.2	79.3	61.5
1980	76.3	79.2	62.4

¹Includes races other than white and black.

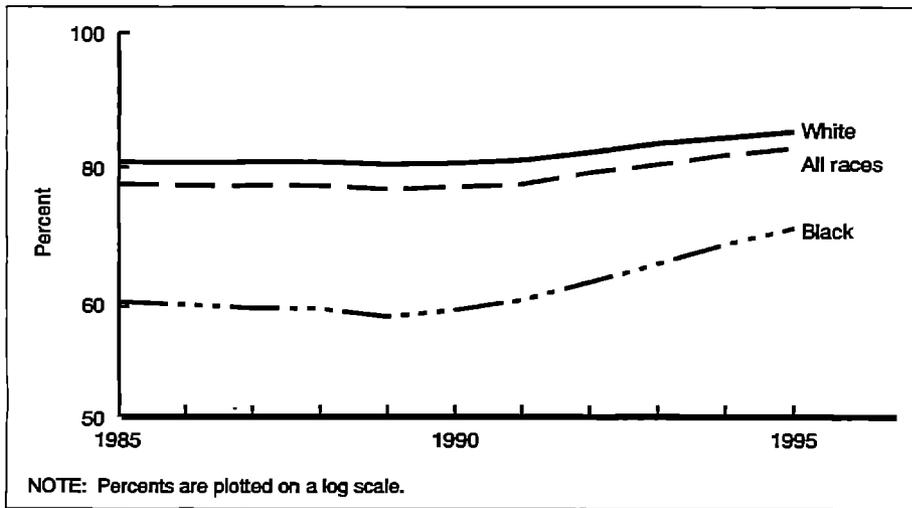

Figure 5. Percent of mothers with first trimester prenatal care by race of mother: United States, 1985–95

The proportion of American Indian mothers who received first trimester prenatal care was up slightly to 66.7 percent for 1995, but this level was still lower than that of any of the racial or ethnic groups studied. Concurrently, the percent of American Indian mothers with late or no care (9.5 percent for 1995) was the highest reported (table 23).

No substantial changes were observed in prenatal care utilization among Asian or Pacific Islander mothers from the previous year. Among subgroups, the percent of mothers with first trimester care ranged from 89.7 percent of Japanese mothers to 75.9 percent of Hawaiian mothers (table 23).

Among all Hispanic mothers, first trimester prenatal care rose from 68.9 to 70.8 percent and late or no care declined slightly from 7.6 to 7.4 percent for 1994–95. (See table 24 for 1995 data.) Since 1989 prenatal care utilization among Hispanic mothers has improved mark-

edly; early care has risen 19 percent (from 59.5 percent) and late or no care has fallen 76 percent (from 13.0 percent). Large differences among Hispanic subgroups in care utilization persist—for 1995, 89.2 percent of Cuban mothers received early care compared with 69.1 percent of Mexican American mothers—but the gap is narrowing as larger gains occur among groups with lower levels.

At least 10 prenatal visits are recommended for an uncomplicated term pregnancy of 37 completed weeks of gestation or more (61). For 1995 the median number of prenatal visits for all gestations, including complicated pregnancies, was 12.2, unchanged from 1994 (table 35). There has been only small change in this measure since 1987 (12.0 visits). The median for white mothers was also unchanged at 12.3 visits. The median number of visits rose among black mothers, however, from 11.1 to 11.4.

The proportion of white mothers with first trimester care increased slightly or was essentially unchanged for nearly all States for the current year (table 34). Among States reporting at least 1,000 births to black mothers, levels rose in the vast majority of States, and increases of at least 4 percent were noted for Colorado, Delaware, Georgia, Minnesota, New Jersey, New York, North Carolina, Oklahoma, Pennsylvania, South Carolina, and Texas.

Obstetric procedures

The most prevalent obstetric procedure in 1995 was electronic fetal monitoring (EFM), reported for over 3.1 million births, or 81 percent of all live births (table 36). EFM usage in 1995 rose for the sixth consecutive year, reflecting continuing increases in all age groups. Hawaiian mothers had the highest (82 percent) and Filipino mothers had the lowest (73 percent) rates in EFM usage in 1995 (table 26). For Hispanic mothers, the lowest rate was observed for Mexican American mothers (73 percent) (table 27).

According to data from the birth certificate 61 percent of mothers who had live births in 1995 received ultrasound, the same as in 1994 but a 27-percent increase over 1989 (48 percent).

The overall rates of stimulation of labor and induction of labor in 1995 were 161 and 160 per 1,000 live births, respectively, about 6 and 9 percent above their levels in 1994. The rates of both procedures have risen steadily every year since 1989, stimulation by about 48 percent (from 109 per 1,000) and induction by 78 percent (from 90 per 1,000).

Amniocentesis, an invasive prenatal diagnostic procedure performed to detect genetic disorders, was reported for 32 of every 1,000 live births in 1995. The rate of amniocentesis increases sharply with advancing maternal age. In 1995 the rate for mothers aged 40–49 years (189 per 1,000) was 19 times the rate for mothers under age 20 years (10 per 1,000).

Complications of labor and/or delivery

Of the 15 reported complications of labor and/or delivery, 4 were reported at a rate greater than or equal to 30 per 1,000

live births in 1995; meconium, moderate/heavy (57 per 1,000), fetal distress (42 per 1,000), breech/malpresentation (37 per 1,000), and premature rupture of membrane (31 per 1,000) (table 37). For these four complications there were observable variations by race and Hispanic origin (tables 26 and 27).

Although not frequent, placenta previa is a serious complication that occurred in nearly 13,000 births in 1995. Data from birth certificates identify increasing age of mother and live-birth order as two risk factors for this complication (62).

Attendant at birth and place of delivery

A physician-attended delivery in a hospital setting was by far the most common approach to delivery in 1995, comprising 93.4 percent of all births (table 38). For physician-attended births, only about 4 percent were by doctors of osteopathy (DO's) and the remaining were attended by doctors of medicine (MD's). The percent of births attended by physicians was slightly lower than in 1994 (93.7 percent) and has declined from 98.4 percent in 1975. During the 1975–95 period, the percent of births attended by midwives increased sharply, from 0.9 percent in 1975 to 6.0 percent in 1995. About 94 percent of midwife-delivered births were by certified nurse midwives (CNM), and the remaining 6 percent by "other" midwives. CNM-attended deliveries were almost universally in hospitals (96 percent) whereas deliveries by "other" midwives were most likely in a residence (64 percent). A recent article presents more detailed information on the trends and characteristics of midwife-attended births (63).

Altogether, 99 percent of births in 1995 were delivered in hospitals, almost unchanged from the 1975 level. The majority of out-of-hospital births were in a residence (63 percent) while 27 percent were in a freestanding birthing center. Birthing centers have been shown to be a cost-effective, safe alternative to a hospital setting for low-risk women (64).

About 9 out of 10 births for white and black women were attended by MD's in a hospital setting. However, there were some differences between white and black women in the attendant and place of

delivery. For hospital births, black women were slightly less likely than white women to have births attended by DO's (2.5 and 4.0 percent, respectively) but more likely to have CNM-attended births (6.1 and 5.1 percent, respectively). For out-of-hospital births, black women were more likely than white women to have births attended by MD's and less likely to have midwife-attended births. For example, for births occurring in a residence more than half of those to white women were attended by a midwife (53 percent) compared with only 8 percent of births to black women. In contrast, MD's attended the births of only 9 percent of white women delivering in a residence compared with 39 percent of black women.

In general, the proportion of births to teenaged and unmarried women was higher in hospitals than in most other places of delivery (data not shown). About 13 percent of births in hospitals were to teenagers compared with about 10 percent of births in clinics or doctor's offices, 8 percent of births in birthing centers, and 6 percent of home births. Similarly, almost a third of hospital births were to unmarried women (32 percent) compared with 26 percent of births in clinics or doctor's offices, 22 percent in residences, and 17 percent in birthing centers.

Method of delivery

The rate of cesarean delivery declined for the sixth consecutive year and was 9 percent lower in 1995 (20.8 per 100 live births) than in 1989 (22.8), the first year this information was available on the birth certificate (text table E and table 39). Similarly, the primary cesarean rate (first cesareans per 100 live births to women

who had no previous cesarean) also declined each year and was 9 percent lower in 1995 (14.7) than in 1989 (16.1). Concomitant with the decline in cesarean rates during this period was a 46-percent increase in the rate of vaginal birth after previous cesarean delivery (VBAC)—from 18.9 in 1989 to 27.5 in 1995. A detailed analysis of trends in cesarean and VBAC rates for 1991–95 is published elsewhere (65).

Despite the favorable trends, the cesarean and VBAC rates still fall short of the year 2000 objectives (overall cesarean rate—15 or lower; primary cesarean rate—12 or lower; VBAC rate—35 or higher) (66). However, some States are approaching or have already achieved these rates. Alaska was the only State in 1995 that had achieved an overall cesarean rate of 15 or lower (14.4) (tabular data not shown). Three other States (Colorado, Idaho, and Wisconsin) were approaching the year 2000 objective with overall cesarean rates that were less than 16. Nine States had already achieved primary cesarean rates of 12 or lower with Alaska having the lowest rate (10.2). Eight States had VBAC rates of 35 or higher with Colorado having the highest rate (40.4).

Overall cesarean rates increased almost linearly by age of mother and were more than twice as high for mothers 40–49 years of age (31.6) than for teenagers (14.7) (table 40). Primary cesarean rates increased with additional age after age 25 but the differences between age categories were smaller than for the overall cesarean rates. VBAC rates declined with increasing age—almost a third of teenagers who had a previous cesarean had a VBAC delivery (32.3 percent) compared

Table E. Total and primary cesarean rates and vaginal birth after previous cesarean delivery rates: United States, 1989–95

Year	Cesarean rate		
	Total ¹	Primary ²	VBAC rate ³
1995	20.8	14.7	27.5
1994	21.2	14.9	26.3
1993	21.8	15.3	24.3
1992	22.3	15.6	22.6
1991	22.6	15.9	21.3
1990	22.7	16.0	19.9
1989	22.8	16.1	18.9

¹Percent of all live births by cesarean delivery.

²Number of primary cesareans per 100 live births to women who have not had a previous cesarean.

³Number of vaginal births after previous cesarean (VBAC) delivery per 100 live births to women with a previous cesarean delivery.

with 21 percent of mothers 40–49 years of age. Compared with 1994, most age groups had lower overall and primary rates and all had higher VBAC rates in 1995.

The cesarean rate in 1995 for black women (21.8) was 5 percent higher than the rate for white women (20.8). The primary cesarean rate for black women (15.7) was 8 percent higher than the rate for white women (14.6). Between 1989 and 1995 cesarean rates for black women have remained relatively steady while rates for white women have fallen by about 10 percent. The VBAC rate in 1995 was 6 percent higher for white than black women, 27.6 compared with 26.1, due to greater increases since 1989 for white than black women. In 1995 overall and primary cesarean rates for every age category were higher for black than white women. VBAC rates for black mothers were higher than for white mothers at ages under 25 years but were lower than for white mothers at older ages.

With the exception of Filipino mothers, all specified categories of Asian or Pacific Islander mothers had lower rates of cesarean delivery than either white or black mothers (table 23). The rate of cesarean delivery for American Indian mothers (18.1) was also lower than for white and black mothers.

The rate of cesarean delivery was lower for Hispanic mothers (20.2) than for either non-Hispanic white mothers (21.0) or non-Hispanic black mothers (21.8) (table 24). The rate of cesarean delivery varied between 19.7 and 21.2 for all Hispanic subgroups except for Cuban mothers whose rate was much higher (30.2).

All of the selected medical risk factors in table 41 were associated with overall cesarean rates that were higher than the national average. Cesarean rates for the medical risk factors ranged from 21.3 for mothers with Rh sensitization to 49.1 for mothers with eclampsia. Other medical risk factors in which more than a third of births were by cesarean were chronic hypertension (39.6), hydramnios/oligohydramnios and genital herpes (37.8), pregnancy-associated hypertension (36.8), and diabetes (35.4). Certain complications of labor and/or delivery are also associated with high cesarean rates. Nearly

all births with cephalopelvic disproportion were cesarean deliveries (96.9) and the cesarean rates for breech/malpresentation (85.1) and placenta previa (81.8) were also very high. In addition, more than half of births with dysfunctional labor (63.4), cord prolapse (63.1), abruptio placenta (57.7), and fetal distress (54.9) were by cesarean delivery. Obstetric procedures with cesarean rates above the national average were amniocentesis (31.9), tocolysis (27.5), and ultrasound (22.4). Cesarean rates for most of the medical risk factors, complications of labor and/or delivery, and obstetric procedures have declined since 1989.

During the 1989–95 period, the percent of births that were delivered by forceps declined each year whereas the use of vacuum extraction consistently increased. In 1995, 3.5 percent of births were delivered by forceps compared with 5.5 percent in 1989—a 36-percent decline. Vacuum extraction was used in 5.9 percent of births in 1995, a 69-percent increase compared with 1989 (3.5). As in previous years, forcep- and vacuum-extraction deliveries were slightly more common in births to white than black mothers.

Infant health characteristics

Period of gestation

The rate of preterm birth was 11.0 percent for 1995, unchanged since 1993. The preterm birth rate (prior to 37 completed weeks of gestation) has risen 17 percent since 1981 (from 9.4 percent). (See tables 42, 43, and figure 6.) Preterm birth is a major cause of infant mortality and morbidity; infants born preterm are 28 times more likely to die within the first month of life as are term infants (37–41 weeks) (67). Preterm newborns who survive are at greater risk of neurodevelopmental and respiratory disorders, as well as other problems (68).

The primary method used to determine the gestational age of the newborn from birth certificate data is the interval between the first day of the mother's last normal menstrual period (LMP) and the date of birth. It is subject to error for several reasons including imperfect maternal recall or misidentification of the LMP because of postconception bleeding,

delayed ovulation, or intervening early miscarriage. Since 1989 the "clinical estimate of gestation," which is the birth attendant's estimate of gestational age based on ultrasound or other techniques, has been used when the LMP is inconsistent with birthweight or unknown. For 1995 the clinical estimate was used for about 5 percent of the 6 percent of records with missing or invalid data.

Among births to white mothers, the preterm rate increased slightly from 9.6 to 9.7 percent between 1994 and 1995. Since 1981 the preterm rate for white births has risen 23 percent (from 7.9 percent). The rise between 1994 and 1995 included all age groups except mothers under 20 years of age.

The proportion of preterm births among black mothers fell from 18.1 to 17.7 percent between 1994 and 1995. This rate had risen to 18.9 percent for the late 1980's and early 1990's, and the current year is the first since 1985 that this level has dropped below 18 percent. The decline between 1994 and 1995 was most pronounced among births of 32–36 completed weeks of gestation. Preterm levels were lower for 1995 among births to black mothers in nearly all age groups.

For 1995, 12.4 percent of births to American Indian mothers were born preterm, a slight increase over the level reported for 1994 (12.1 percent) (table 23). Among births to Asian or Pacific Islander mothers, the most marked improvement in preterm levels was for Hawaiian births, for whom the rate declined from 12.2 to 11.0 percent. For 1995 the percent of preterm births ranged from 7.2 percent for Chinese births to 11.7 percent for Filipino births. Among Hispanic births the preterm birth rate was largely unchanged. Rates ranged from 10.1 percent for Cuban births to 13.4 percent for Puerto Rican births (table 24).

Birthweight

The percent low birthweight (LBW) (less than 2,500 grams) was 7.3 for 1995, unchanged from 1994. Following declines during the 1970's and early 1980's LBW has risen 9 percent since 1984 (from 6.7 percent). (See table 43 and figure 7.) The percent very low birthweight (VLBW) (less than 1,500 grams) was 1.35 percent

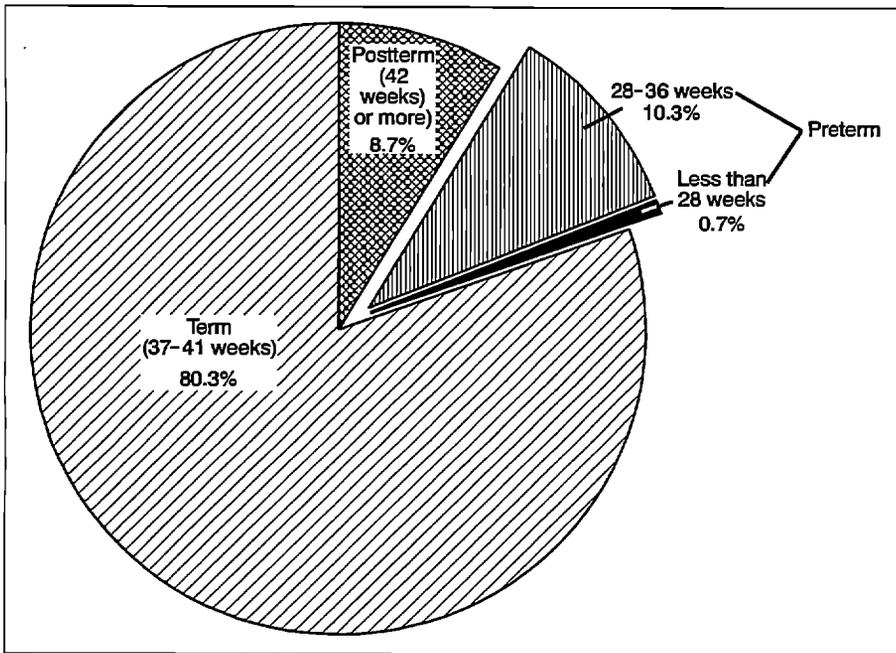

Figure 6. Gestation distribution: United States, 1995

for 1995. This level has increased gradually between 1980 and 1995 from 1.15 (text table F). Although medical advances have greatly improved the survival of LBW infants (70-72), they continue to be at much greater risk than heavier babies of mortality and long-term disability. Infants with birthweights of 1,500-2,499 grams are about 5 times more likely than heavier infants to die during the first year

of life, and the risk of early death for VLBW infants is about 65 times that of infants who weigh at least 1,500 grams (67).

LBW rose slightly among births to white mothers (from 6.1 to 6.2 percent) between 1994 and 1995. Since the early 1980's, overall LBW among white births of all pluralities has increased by 11 percent (from 5.6 percent), and among

singleton births by 6 percent (from 4.7 to 5.0 percent between 1992 and 1995). LBW rose slightly among white preterm births (births of less than 37 completed weeks of gestation), but was unchanged among births of longer gestations. Increases in white LBW were observed for nearly all age groups. For the current year, the percent VLBW for white births increased slightly from 1.02 to 1.06 percent, the highest level reported since at least 1970.

Among black mothers, the percent LBW declined from 13.2 to 13.1 between 1994 and 1995, continuing a downward trend observed since 1992. Most of the improvement in LBW was in the moderately LBW range (1,500-2,499); the proportion VLBW was essentially unchanged at 2.97 percent.

Much of the disparity between black and white births in LBW can be attributed to the much higher incidence of preterm births among black mothers (17.7 compared with 9.7 percent), because of the greater risk of LBW for preterm births. However, black infants are also more likely to be LBW at longer gestations. For example, for 1995 as for earlier years, the LBW risk for black infants born at term (37-41 completed weeks of gestation) was more than twice that of white term infants (5.5 percent compared with 2.5 percent).

LBW increased or was unchanged between 1994 and 1995 among infants born to mothers of other racial or ethnic groups (tables 23 and 24). The only exception was for Hawaiian births, among whom LBW declined from 7.2 to 6.8 percent. Rates among other racial or ethnic groups ranged widely for 1995, from 5.3 percent for births to Chinese mothers, to 9.4 percent for births to Puerto Rican mothers.

The risk of LBW is highest at the two extremes of the maternal age range with risk slightly more elevated for mothers 40 years of age and over (table 44). When only singleton births are examined however, (multiple births are more common among older mothers, and are more likely to be LBW), the level of LBW was 10 percent higher for mothers under 20 years of age than for mothers 40 years of age and over. (Tabular data not shown.)

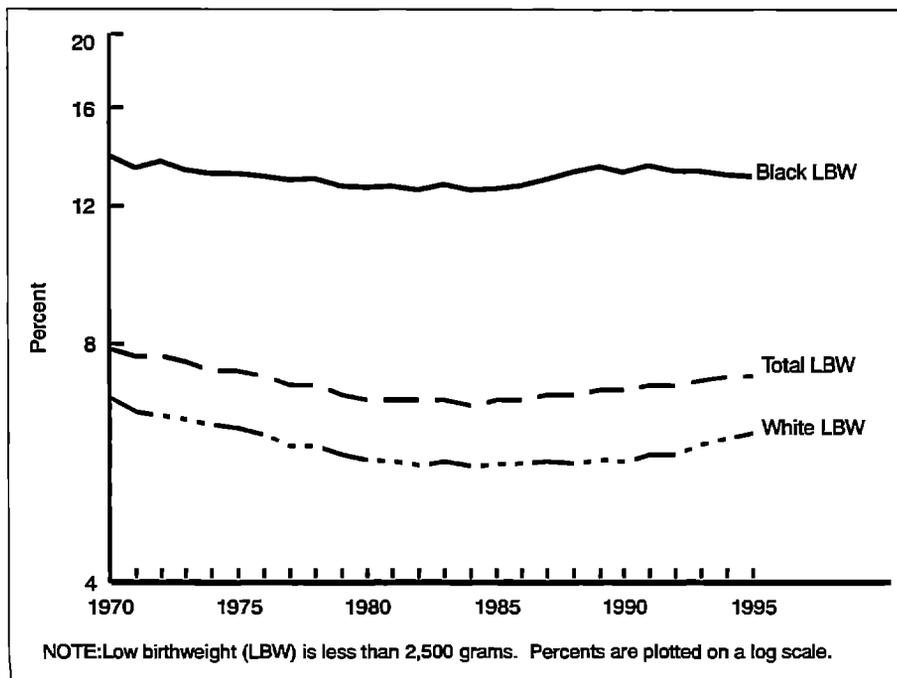

Figure 7. Percent low birthweight by race of mother: United States, 1970-95

Table F. Percent very low birthweight by race of mother: United States, 1980 and 1985–1995

Year	All races ¹	White	Black
1995	1.35	1.06	2.97
1994	1.33	1.02	2.96
1993	1.33	1.01	2.96
1992	1.29	0.96	2.96
1991	1.29	0.96	2.96
1990	1.27	0.95	2.92
1989	1.28	0.95	2.95
1988	1.24	0.93	2.86
1987	1.24	0.94	2.79
1986	1.21	0.93	2.73
1985	1.21	0.93	2.71
1980 ²	1.15	0.90	2.48

¹Includes races other than white and black.

²Based on 100 percent of births in selected States and a 50-percent sample in all other States.

NOTE: Very low birthweight is equal to less than 1,500 grams (3 pounds, 4 ounces).

The median birthweight for 1995 was 3,350 grams (7 lb 7 oz) slightly lower than the median reported for 1994 (3,360) and the lowest figure reported since 1978.

The percent macrosomia (birthweight of at least 4,000 grams) declined for 1995 to 10.3 percent of all births. This level has been decreasing since 1991, after peaking at about 11 percent in the 1980's.

For the majority of States LBW for white births increased or was unchanged between 1994 and 1995. However, declines of at least 5 percent occurred in five States; Hawaii, Montana, Vermont, Wisconsin, and Wyoming. Rates ranged from 5.1 percent for Alaska, North Dakota, and Wisconsin, to 8.0 and 7.7 percent in Colorado and New Mexico. LBW declined in about half of the areas reporting at least 1,000 black births. LBW levels for black infants ranged from 10.4 percent for Massachusetts to 15.9 percent for the District of Columbia and Colorado.

Apgar score

The Apgar score was developed by the late Virginia Apgar, M.D., as a means of evaluating the physical condition of newborns shortly after delivery (73). The score considers five characteristics of the baby that are easily identifiable—heart rate, respiratory effort, muscle tone, reflex irritability, and color. Each of these characteristics is assessed and assigned a value of 0–2, with 2 being optimum. The total score is the sum of the scores of the five components and a score of 7 or greater indicates that the baby is in good to excellent physical condition. The Apgar

score is assessed at 1 and 5 minutes after delivery and used to predict the baby's survival chances with the 5-minute score regarded as the better measure on which to make predictions.

Beginning in 1995, NCHS is collecting information on the 5-minute score only. In 1995 every State except California and Texas collected information on the 5-minute Apgar score. Births to residents of these States accounted for 78 percent of all births in the United States. Only 1.4 percent of babies had Apgar scores that were considered low (less than 7) at 5 minutes after birth, unchanged from 1993 and 1994 (table 23). The percent of infants with low 5-minute Apgar scores declined sharply between 1984–90, from 2.0 to 1.5, but has changed very little since then.

Of all racial groups, Asian or Pacific Islander babies were in the best physical condition shortly after delivery (table 23). This was particularly true for Japanese and Chinese babies—less than 1 percent had low 5-minute scores. The percent of babies with low scores was intermediate for white and American Indian mothers, between 1.2–1.4, whereas 2.5 percent of black babies had low 5-minute scores.

Non-Hispanic black mothers were twice as likely to have babies with low 5-minute scores (2.5 percent) than either Hispanic mothers or non-Hispanic white mothers (each with 1.2 percent) (table 24). Among Hispanic subgroups, the percent of babies with low 5-minute scores ranged from 0.7 for Cuban mothers to 1.4 percent for Puerto Rican mothers.

In general, the variation among racial and ethnic groups in the percent of babies

with low 5-minute Apgar scores was consistent with the percent of babies that were born preterm or with low birthweight (tables 23, 24).

Abnormal conditions of the newborn

Of the eight specific abnormal conditions reported on the birth certificate the three highest rates per 1,000 live births in 1995 were for assisted ventilation less than 30 minutes (19 per 1,000), assisted ventilation 30 minutes or longer (8 per 1,000), and hyaline membrane disease/respiratory distress syndrome (RDS) (7 per 1,000). It has been shown that these conditions may be underreported on the birth certificate (74).

The rates for abnormal conditions in 1994 were higher for black births than for white births for all conditions except birth injuries (table 45).

Birth injury and meconium aspiration syndrome had lower rates among low birthweight infants (less than 2,500 grams) than among infants weighing 2,500 grams or more. Rates of hyaline membrane disease/RDS were far higher for LBW infants than those of higher weight (55 compared with 3 per 1,000 live births); there were similar large differences in rates by birthweight for assisted ventilation 30 minutes or longer (65 and 4 per 1,000 live births) (tabular data not shown).

Congenital anomalies

Since 1989 information for some of the most severe and common congenital anomalies has been available from a checkbox item on live-birth certificates. In 1995 the District of Columbia and all States except Maryland, New Mexico, and New York City reported congenital anomalies in the standard categories. These areas included 94 percent of births in the United States. It has been shown that these anomalies are underreported on the birth certificate (74,75).

Because many of the congenital anomalies tracked on birth certificates occur infrequently, the rates shown in this report are calculated per 100,000 live births. Caution should be used in comparing yearly rates for a specific anomaly as a small change in the number of anomalies reported can result in a relatively large change in rates.

Rates for several of the anomalies reported on the birth certificates vary considerably by age of mother (table 46). As an example, the rate for Down's syndrome for births to mothers 40–49 years, 331 per 100,000 live births, was 13 times higher than the rate of 26 for mothers aged 20–24 years.

Multiple births

The number of live births in multiple deliveries for 1995 was 101,709, only slightly higher than the number reported for 1994 (101,658). The multiple birth ratio (the number of multiple births per 1,000 live births) rose 2 percent to 26.1 per 1,000. (See table 47.) The number of twin births declined (from 97,064 to 96,736), but the number of higher order multiple births (triplet, quadruplet, quintuplet, and other higher order multiple births) increased by 8 percent. The 4,973 births in higher order multiple deliveries included 4,551 triplet, 365 quadruplet, and 57 quintuplet or greater multiples. Since 1980 the number of twin births has risen by 42 percent (from 68,339), and the number of higher order multiple births by 272 percent (from 1,337) (76,77).

The risk of adverse pregnancy outcome rises with the number of births in the delivery. For 1995, 53 percent of twins and 92 percent of triplets were born pre-term (less than 37 completed weeks of gestation) compared with 10 percent of singleton births (data not shown). Moreover, twins are 5 times and triplets 12 times more likely than singletons to die within the first year of life (67).

The 1994–95 decline in twin births was the result of a 7-percent decline in the number of twins born to black mothers (from 18,344 to 17,000). The black twin birth ratio (the number of twin births per 1,000 live births) also declined, albeit at a slower pace (2 percent). In contrast, the number of twins born to white mothers rose 1 percent and the twin birth ratio by 2 percent. Since 1980 there has been an 18-percent rise in the black twin birth ratio (from 24.0 to 28.2 per 1,000) and a 36 percent rise in the white ratio (from 18.1 to 24.6 per 1,000).

The higher order multiple birth ratio (the number of triplet and greater multiple births per 100,000 live births) rose

10 percent for the current year, from 116.2 to 127.5 per 100,000. Since 1987 this ratio has increased by an average of 11 percent a year. While still comparatively rare (only 0.1 percent of all births were higher order multiples in 1995), higher order multiple births have become much more common in recent years; the ratio has doubled since only 1989, tripled since the early 1980's, and quadrupled since the early 1970's. (See figure 8.) Put another way, in the early 1970's, about 1 of 3,500 births was a triplet compared with 1 of 785 births in 1995.

Nearly all higher order multiple births are born to white mothers (91 percent compared with 79 percent of singleton births), and most of the recent rise in the higher order multiple birth ratio can be attributed to increases among these mothers. The white higher order multiple birth ratio increased 10 percent to 145.4 per 100,000 between 1994 and 1995, and has nearly quadrupled since 1980 (from 37.6). Birth certificate data do not identify births resulting from the use of fertility enhancing techniques (ovulation-inducing drugs and assisted reproductive techniques such as in vitro fertilization), but it is estimated that about a third of the growth in the higher order multiple birth ratio since 1980 is the result of the older maternal age distribution of recent years (the risk of having a multiple birth increases with maternal age), and the remaining two-thirds is the result of increases in the use of fertility-enhancing therapies (77–79).

13. Live births by day of week and index of occurrence, by method of delivery, day of week, and race of mother: United States, 1995 39

14. Number, rate, and ratio of births to unmarried women by age and race of mother: United States, 1995 40

15. Birth rates for unmarried women by age of mother and race: United States, 1970, 1975, and 1980-95 41

16. Number and percent of births to unmarried women and number and percent of births of low birthweight, by race of mother: United States and each State, 1995 43

17. Birth rates by age and race of father: United States, 1980-95 44

18. Live births by educational attainment of mother, by age and race of mother: United States, 1995 45

19. Number of live births and percent distribution by weight gain during pregnancy and median weight gain, according to period of gestation and race of mother: Total of 49 reporting States and the District of Columbia, 1995 46

20. Percent low birthweight by weight gain during pregnancy, period of gestation and race of mother: Total of 49 reporting States and the District of Columbia, 1995 47

21. Number of live births and percent distribution by weight gain during pregnancy and median weight gain, according to period of gestation, Hispanic origin of mother, and race of mother for mothers of non-Hispanic origin: Total of 49 reporting States and the District of Columbia, 1995 48

22. Percent low birthweight by weight gain during pregnancy and Hispanic origin of mother, and by race of mother for mothers of non-Hispanic origin: Total of 49 reporting States and the District of Columbia, 1995 49

23. Percent of births with selected medical or health characteristics, by specified race of mother: United States, 1995 49

24. Percent of births with selected medical or health characteristics, by Hispanic origin of mother and by race of mother for mothers of non-Hispanic origin: United States, 1995 50

25. Live births with selected medical risk factors and rates by age of mother, by race of mother: United States, 1995 51

26. Number and rate of live births with selected medical risk factors, complications of labor, and obstetric procedures, by specified race of mother: United States, 1995 52

27. Number and rate of live births with selected medical risk factors, complications of labor, and obstetric procedures, by Hispanic origin of mother and by race of mother for mothers of non-Hispanic origin: United States, 1995 53

28. Number of live births by smoking status of mother, percent smokers, and percent distribution by average number of cigarettes smoked by mothers per day, according to age and race of mother: Total of 46 reporting States, the District of Columbia, and New York City, 1995 54

29. Number of live births by smoking status of mother and percent smokers, by age and Hispanic origin of mother and by race of mother for mothers of non-Hispanic origin: Total of 46 reporting States, the District of Columbia, and New York City, 1995 55

30. Number of live births, percent of mothers who smoked cigarettes during pregnancy, and percent distribution by average number of cigarettes smoked by mothers per day, according to educational attainment and race of mother: Total of 46 reporting States, the District of Columbia, and New York City, 1995 56

31. Percent low birthweight by smoking status, age, and race of mother: Total of 46 reporting States, the District of Columbia, and New York City, 1995 57

32. Number of live births by drinking status of mother, percent drinkers, and percent distribution by average number of drinks per week, according to age and race of mother: Total of 48 reporting States and the District of Columbia, 1995 58

33. Live births by month of pregnancy prenatal care began and percent of mothers beginning care in the first trimester and percent with late or no care, by age and race of mother: United States, 1995 59

34. Percent of mothers beginning prenatal care in the first trimester and percent of mothers with late or no prenatal care, by race of mother: United States and each State, 1995 60

35. Live births by month of pregnancy prenatal care began, number of prenatal visits, and median number of visits, by race of mother: United States, 1995 61

Table 1. Live births, birth rates, and fertility rates, by race: United States, specified years 1940-55 and each year, 1960-95

[Birth rates are live births per 1,000 population in specified group. Fertility rates per 1,000 women aged 15-44 years in specified group. Population enumerated as of April 1 for census years and estimated as of July 1 for all other years. Beginning with 1970, excludes births to nonresidents of the United States]

Year	Number					Birth rate					Fertility rate				
	All races ¹	White	Black	American Indian ²	Asian or Pacific Islander	All races ¹	White	Black	American Indian ²	Asian or Pacific Islander	All races ¹	White	Black	American Indian ²	Asian or Pacific Islander

— Data not available.

¹ For 1960-91 includes births to races not shown separately.

² Includes births to Aleuts and Eskimos.

³ Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.

⁴ Based on a 50-percent sample of births.

⁵ Based on a 20- to 50-percent sample of births.

⁶ Figures by race exclude New Jersey.

Table 2. Live births by age of mother, live-birth order, and race of mother: United States, 1995

[Live-birth order refers to number of children born alive to mother]

* Figure does not meet standards of reliability or precision.

0.0 Quantity more than zero but less than 0.05.

¹ Rates computed by relating total births, regardless of age of mother, to women aged 15-44 years.

² Includes births to Aleuts and Eskimos.

Table 4. Total fertility rates and birth rates by age of mother and race: United States, 1970-95

[Total fertility rates are sums of birth rates for 5-year age groups multiplied by 5. Birth rates are live births per 1,000 women in specified group, enumerated as of April 1 for 1970, 1980 and 1990, and estimated as of July 1 for all other years]

Year and race	Total fertility rate	Age of mother

* Figure does not meet standards of reliability or precision.

1 For 1970-81 includes births to races not shown separately.

2 Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.

3 Based on a 50-percent sample of births.

4 Includes births to Aleuts and Eskimos.

Table 5. Birth rates by live-birth order and race of mother: United States, 1980-95

[Rates are live births per 1,000 women aged 15-44 years, enumerated as of April 1 for 1980 and 1990, and estimated as of July 1 for all other years. Figures for live-birth order not stated are distributed]

0.0 Quantity more than zero but less than 0.05.

* Figure does not meet standards of reliability or precision.

1 Rates computed by relating total births, regardless of age of mother, to women aged 15-44 years.

2 Includes Central and South American and other and unknown Hispanic.

3 Includes origin not stated.

4 Includes races other than white and black.

Table 8. Live births by race of mother, birth rates, and fertility rates: United States and each State, Puerto Rico, Virgin Islands, and Guam, 1995

[By place of residence. Birth rates per 1,000 estimated population in each area; fertility rates per 1,000 women aged 15-44 years estimated in each area]

— Data not available.

¹ Includes races other than white and black.

² Persons of Hispanic origin may be of any race.

³ Rates computed by relating total births to unmarried mothers, regardless of age of mother, to unmarried women aged 15-44 years.

⁴ Rates computed by relating births to unmarried mothers aged 40 years and over to unmarried women aged 40-44 years.

NOTE: For 45 States and the District of Columbia, marital status of mother is reported on the birth certificate; for 5 States, mother's marital status is inferred; see Technical notes.

Table 15. Birth rates for unmarried women by age of mother and race: United States, 1970, 1975, and 1980-95

[Rates are live births to unmarried women per 1,000 unmarried women in specified group, estimated as of July 1]

1 Rates computed by relating total births to unmarried mothers, regardless of age of mother, to unmarried women aged 15-44 years.

2 Rates computed by relating births to unmarried mothers aged 40 years and over to unmarried women aged 40-44 years.

3 Includes races other than white and black.

4 Data for States in which marital status was not reported have been inferred and included with data from the remaining States; see Technical notes.

5 Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.

6 Births to unmarried women are estimated for the United States from data for registration areas in which marital status of mother was reported; see Technical notes.

7 Based on a 50-percent sample of births.

Table 16. Number and percent of births to unmarried women and number and percent of births of low birthweight, by race of mother: United States and each State, Puerto Rico, Virgin Islands, and Guam, 1995

- Quantity zero.

* Figure does not meet standards of reliability or precision.

¹ For 45 States and the District of Columbia, marital status of mother is reported on the birth certificate; for 5 States, mother's marital status is inferred, see Technical notes.

² Less than 2,500 grams (5 lb 8 oz).

³ Includes races other than white and black.

⁴ Excludes data for Puerto Rico, Virgin Islands, and Guam.

Table 17. Birth rates by age and race of father: United States, 1990-95

[Rates are live births per 1,000 men in specified group, enumerated as of April 1 for 1980 and 1990 and estimated as of July 1 for all other years. Figures for age of father not stated are distributed]

¹ Rates computed by relating total births, regardless of age of father, to men aged 15-54 years.

² Rates computed by relating births of fathers under 20 years of age to men aged 15-19 years.

³ Includes races other than white and black.

⁴ Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.

¹ Percent of all live births by cesarean delivery.

² Number of primary cesareans per 100 live births to women who have not had a previous cesarean.

³ Number of vaginal births after previous cesarean delivery per 100 live births to women with a previous cesarean delivery.

⁴ Includes races other than white and black.

⁵ Excludes data for Oklahoma, which did not report method of delivery on the birth certificate.

⁶ Excludes data for Louisiana, Maryland, Nebraska, Nevada, and Oklahoma, which did not report method of delivery on the birth certificate.

Table 40. Live births by method of delivery, and rates of cesarean delivery and vaginal birth after previous cesarean delivery, by age and race of mother: United States, 1995

Technical notes

Source of data

Data shown in this report for 1995 are based on 100 percent of the birth certificates in all States and the District of Columbia. The data are provided to the National Center for Health Statistics (NCHS) through the Vital Statistics Cooperative Program (VSCP). In 1984 and earlier years, the VSCP included varying numbers of States that provided data based on 100 percent of their birth certificates. Data for States not in the VSCP were based on a 50-percent sample of birth certificates filed in those States. Information on sampling procedures and sampling errors for 1984 and earlier years is provided in the annual report, *Vital Statistics of the United States*, Volume I, Natality (11).

Race

Beginning with the 1989 data year, NCHS is tabulating its birth data primarily by race of mother. In 1988 and prior years, births were tabulated by race of child, which was determined from the race of the parents as entered on the birth certificate.

Trend data by race shown in this report are by race of mother for all years beginning with the 1980 data year. In order to facilitate continuity and analysis of the data, trend tables showing data for years prior to 1980 show data for both race of mother and race of child for 1980. This makes it possible to distinguish the effects of this change from real changes in the data. The text in this report focuses on data tabulated by race of mother. Text references to white births and white mothers or black births and black mothers are used interchangeably for ease in writing.

The factors influencing the decision to tabulate births by race of mother have been discussed in detail in previous reports (4–8). They include the recent revision of the birth certificate, effective with the 1989 data year, which includes many more health questions that are directly associated with the mother. In all these instances, it is more appropriate to tabulate births by the mother's race. A second factor has been the increasing incidence of interracial parentage. In 1995, 4.6

percent of births were to parents of different races compared with just 1.8 percent in 1975. The third factor influencing the decision to tabulate births by race of mother is the growing proportion of births with race of father not stated, 15 percent in 1995 compared with 8 percent in 1975. This reflects the increase in the proportion of births to unmarried women; in many such cases, no information is reported on the father. These births are already assigned the race of the mother because there is no alternative.

Tabulating all births by race of mother, therefore, provides for a more uniform approach, rather than a necessarily arbitrary combination of parental races. This topic is discussed elsewhere in greater detail (80, 81).

Marital status

National estimates of births to unmarried women are based on two methods of determining marital status. For 1994–95, birth certificates in 45 States and the District of Columbia include a question about the mother's marital status. The mother's marital status is inferred in five States (California, Connecticut, Michigan, Nevada, and New York) by comparing the parents' and child's surnames and other information concerning the father. This procedure represents a substantial departure from the method used before 1980 to prepare national estimates of births to unmarried women, which assumed that the incidence of births to unmarried women in States with no direct question on marital status was the same as the incidence in reporting States in the same geographic division (27).

In the five States that use inferential procedures to compile birth statistics by marital status, there are several basic criteria. A birth is inferred as nonmarital if any of these factors, listed in priority-of-use order, is present: a paternity acknowledgment was received, the father's name is missing, or the father's and mother's current surnames are different. In addition, criteria that are particularly applicable for a given State are also applied as necessary. For example, special procedures are used in California to compare the parents' surnames when they are hyphenated if the parents were born in

countries where naming practices can identify the parents' marital status. This procedure has been in effect for many years for Asian mothers. Beginning in 1995, California applied similar procedures for births to Hispanic mothers. If the child is given a double surname of the mother's and father's surnames (either entire surnames or portions of the parents' hyphenated surnames), regardless of sequence, and the mother is of Hispanic origin, the mother's marital status is coded "Married."

Nevada has also implemented procedures to identify the mother's marital status more accurately. All of Nevada's birth records are now received electronically. Although Nevada does not have a direct question on mother's marital status on the printed birth certificate, this information is being obtained from the electronic birth registration process. In New York (excluding New York City) mother's marital status is inferred as "Unmarried" if the father's name is missing, or if the father's name is given and a paternity acknowledgment is filed.

The current method represents an attempt to use related information on the birth certificate to improve the quality of national data as well as to provide data for the individual nonreporting States. An evaluation of this method and its validity for California (the largest nonreporting State) has been published (82). Because of the continued substantial increases in nonmarital childbearing throughout the 1980's, the data have been intensively evaluated by the Division of Vital Statistics, NCHS. There has been continuing concern that the current method might overstate the number of births to unmarried women because it incorporates data based on a comparison of surnames. This is because women who have retained their maiden surname after marriage and who are frequently older, well-educated women, would be classified as unmarried. The results of this evaluation for changes during 1994–95 differ somewhat for the States reporting marital status and the States inferring this information. Nonmarital births in States reporting mother's marital status directly on the birth certificate declined about 1 percent, whereas nonmarital births in the five nonreporting States declined 7 percent. This disparity

is largely due to the change in reporting procedures in California described above. The overall proportion of births to unmarried mothers in that State declined from 36 percent to 32 percent; California accounted for 54 percent of the births in the nonreporting States in 1995.

One consequence of using nonmarital birth data based on the inferential procedures is the need to monitor continuously the validity of the procedures used by the States to infer mother's marital status. In particular, in recent years, a number of States have extended their efforts to identify the fathers when the parents are not married in order to enforce child support obligations. The presence of a paternity acknowledgment therefore is the most reliable indicator that the birth is nonmarital in the States not reporting this information directly. Changes in reporting procedures in Michigan and Texas, related to paternity acknowledgment, were reported for 1994; the impact of those changes on trends in nonmarital births has been described elsewhere (9).

Gestation

The 1989 revision of the U.S. Standard Certificate of Live Birth includes a new item, "clinical estimate of gestation," that is being compared with length of gestation computed from the date the last normal menstrual period (LMP) began when the latter appears to be inconsistent with birthweight. This is done for normal weight births of apparently short gestations and very low birthweight births reported to be full term. The clinical estimate was also used if the LMP date was not reported. The period of gestation for 5.1 percent of the births in 1995 was based on the clinical estimate of gestation. For 97 percent of these records, the clinical estimate was used because the LMP date was not reported. For the remaining 3 percent, the clinical estimate was used because it was compatible with the reported birthweight, whereas the LMP-based gestation was not. In cases where the reported birthweight was inconsistent with both the LMP-computed gestation and the clinical estimate of gestation, the LMP-computed gestation was used and birthweight was reclassified as "not stated." This was necessary for fewer than 300 births or less than 0.01

percent of all birth records in 1995. The levels of the adjustments in 1995 data were similar to those for 1991–94 (6–9).

Birthweight

Birthweight is reported in some areas in pounds and ounces rather than in grams. However, the metric system has been used in tabulating and presenting the statistics to facilitate comparison with data published by other groups. Equivalents of the gram weights in terms of pounds and ounces are as follows:

Less than 500 grams = 1 lb 1 oz or less
 500–999 grams = 1 lb 2 oz–2 lb 3 oz
 1,000–1,499 grams = 2 lb 4 oz–3 lb 4 oz
 1,500–1,999 grams = 3 lb 5 oz–4 lb 6 oz
 2,000–2,499 grams = 4 lb 7 oz–5 lb 8 oz
 2,500–2,999 grams = 5 lb 9 oz–6 lb 9 oz
 3,000–3,499 grams = 6 lb 10 oz–7 lb 11 oz
 3,500–3,999 grams = 7 lb 12 oz–8 lb 13 oz
 4,000–4,499 grams = 8 lb 14 oz–9 lb 14 oz
 4,500–4,999 grams = 9 lb 15 oz–11 lb 0 oz
 5,000 grams or more = 11 lb 1 oz or more

Method of delivery

Several rates are computed for method of delivery. The overall cesarean section rate or *total cesarean* rate is computed as the percent of all births that were delivered by cesarean section. The *primary cesarean* rate is a measure that relates the number of women having a first cesarean delivery to all women giving birth who have never had a cesarean delivery. The denominator for this rate includes all births less those with method of delivery classified as repeat cesarean, vaginal birth after previous cesarean, or method not stated. The rate for *vaginal birth after previous cesarean* (VBAC) delivery is computed by relating all VBAC deliveries to the sum of VBAC and repeat cesarean deliveries, that is, to women with a previous cesarean section.

Computations of percents, percent distributions, and medians

Births for which a particular characteristic is unknown were subtracted from the figures for total births that were used as denominators before percents, percent distributions, and medians were computed. The median number of prenatal visits also excludes births to mothers who

had no prenatal care. Computations of the median years of school completed and the median number of prenatal visits were based on ungrouped data. An asterisk is shown in place of any derived statistic based on fewer than 20 births in the numerator or denominator.

Population denominators

Birth and fertility rates for 1995 shown in tables 1, 3–5, 7, 10, 11, 14, and 15 are based on populations estimated as of July 1, 1995. Populations consistent with these estimates have been published by the U.S. Bureau of the Census (13) and are based on the 1990 census counts by race and age that were modified to be consistent with the Office of Management and Budget racial categories and historical categories for birth data, and in the case of age, to reflect age as of the census reference date. The modification procedures are described in detail in a census report (83).

Birth and fertility rates by month shown in table 12 are based on monthly population estimates also based on the 1995 estimates. Rates for unmarried women shown in tables 14 and 15 are based on distributions of the population by marital status as of March 1995 provided by the U.S. Bureau of the Census (84), which have been adjusted to July 1995 population levels (13) by the Division of Vital Statistics, NCHS (27).

Birth and fertility rates for the Hispanic population, shown in tables 7 and 11, are based on estimates of the total Hispanic population as of July 1, 1995 (13). Rates for Hispanic subgroups are based on special population estimates (85).

Computation of rates

In computing birth rates by live-birth order, births with birth order not stated were distributed in the same proportion as births of known live-birth order. This procedure is done separately by race. For computing birth rates by age of father, births with age of father not stated are distributed first within each age-of-mother group. This procedure is followed because, while father's age is missing on 15 percent of the birth certificates, one third of these were on records where the mother is a teenager.

In computing birth and fertility rates for the Hispanic population, births with origin of mother not stated are included with non-Hispanic births rather than being distributed. Thus, rates for the U.S. Hispanic population are underestimates of the true rates to the extent that the births with origin not stated (1.5 percent) were actually to Hispanic mothers. The population with origin not stated was imputed. The effect on the rates is believed to be small.

Age of father—Information on age of father is often missing on birth certificates of children born to unmarried mothers, greatly inflating the number of “not stated” in all tabulations by age of father. In computing birth rates by age of father, births tabulated as age of father not stated are distributed in the same proportions as births with known age within each 5-year-age classification of the mother. This procedure is done separately by race. The resulting distributions are summed to form a composite frequency distribution that is the basis for computing birth rates by age of father. This procedure avoids the distortion in rates that would result if the relationship between age of mother and age of father were disregarded.

Graphic presentation

Trend data shown in figures 2, 3, 5, 7, and 8 are plotted using a logarithmic scale. This approach is taken to facilitate comparison of the relative change in rates over time for each series of rates as well as the differentials among rates for different series. The trend lines in figure 2, for example, show that women 40–44 years of age experienced the most change of any group over the period, and also that they had the greatest increase in rates since 1985.

Random variation and relative standard error

Although the birth data in this report for births since 1985 are not subject to sampling error, they may be affected by random variation in the number of births involved. When the number of events is small (perhaps less than 100) and the probability of such an event is small, considerable caution must be observed in interpreting the data. More information

on this topic is included in the Technical Appendix of the annual report, *Vital Statistics of the United States, 1992*, Volume I, Natality. In addition, the relative standard errors for birth rates for Hispanic subgroups, particularly Puerto Rican, Cuban, and “other” Hispanic women, may be somewhat higher than if based only on the number of births. This reflects the considerable sampling variability in the population estimates for these groups (85).

Definitions of medical terms

The 1989 revision of the U.S. Standard Certificate of Live Birth includes several maternal and infant health items in checkbox format, including obstetric procedures, medical risk factors, complications of labor and delivery, abnormal conditions of the newborn, and congenital anomalies of the child (figure 1). The definitions that follow are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics officials for the Association for Vital Records and Health Statistics (86).

Medical risk factors for this pregnancy

Anemia—Hemoglobin level of less than 10.0 g/dL during pregnancy or a hematocrit of less than 30 percent during pregnancy.

Cardiac disease—Disease of the heart.

Acute or chronic lung disease—Disease of the lungs during pregnancy.

Diabetes—Metabolic disorder characterized by excessive discharge of urine and persistent thirst; includes juvenile onset, adult onset, and gestational diabetes during pregnancy.

Genital herpes—Infection of the skin of the genital area by herpes simplex virus.

Hydramnios/oligohydramnios—Any noticeable excess (hydramnios) or lack (oligohydramnios) of amniotic fluid.

Hemoglobinopathy—A blood disorder caused by alteration in the genetically determined molecular structure of hemoglobin (example: sickle cell anemia).

Hypertension, chronic—Blood pressure persistently greater than 140/90,

diagnosed prior to onset of pregnancy or before the 20th week of gestation.

Hypertension, pregnancy-associated—An increase in blood pressure of at least 30 mm Hg systolic or 15 mm Hg diastolic on two measurements taken 6 hours apart after the 20th week of gestation.

Eclampsia—The occurrence of convulsions and/or coma unrelated to other cerebral conditions in women with signs and symptoms of preeclampsia.

Incompetent cervix—Characterized by painless dilation of the cervix in the second trimester or early in the third trimester of pregnancy, with premature expulsion of membranes through the cervix and ballooning of the membranes into the vagina, followed by rupture of the membranes and subsequent expulsion of the fetus.

Previous infant 4,000 grams or more—The birthweight of a previous live-born child was over 4,000 grams or more (8 pounds 14 ounces).

Previous preterm or small-for-gestational-age infant—Previous birth of an infant prior to term (before 37 completed weeks of gestation) or of an infant weighing less than the tenth percentile for gestational age using a standard weight-for-age chart.

Renal disease—Kidney disease.

Rh sensitization—The process or state of becoming sensitized to the Rh factor as when an Rh-negative woman is pregnant with an Rh-positive fetus.

Uterine bleeding—Any clinically significant bleeding during the pregnancy taking into consideration the stage of pregnancy; any second or third trimester bleeding of the uterus prior to the onset of labor.

Obstetric procedures

Amniocentesis—Surgical transabdominal perforation of the uterus to obtain amniotic fluid to be used in the detection of genetic disorders, fetal abnormalities, and fetal lung maturity.

Electronic fetal monitoring—Monitoring with external devices applied to the maternal abdomen or with internal devices with an electrode attached to the fetal scalp and a catheter through the cervix into the uterus, to detect and record fetal heart tones and uterine contractions.

Figure 1. Selected maternal and infant health items from the 1989 revision of the U.S. Standard Certificate of Live Birth.

Induction of labor—The initiation of uterine contractions before the spontaneous onset of labor by medical and/or surgical means for the purpose of delivery.

Stimulation of labor—Augmentation of previously established labor by use of oxytocin.

Tocolysis—Use of medications to inhibit preterm uterine contractions to extend the length of pregnancy and, therefore, avoid a preterm birth.

Ultrasound—Visualization of the fetus and the placenta by means of sound waves.

Complications of labor and/or delivery

Febrile—A fever greater than 100 degrees F. or 38 C. occurring during labor and/or delivery.

Meconium, moderate/heavy—Meconium consists of undigested debris from swallowed amniotic fluid, various products

of secretion, excretion and shedding by the gastrointestinal tract; moderate to heavy amounts of meconium in the amniotic fluid noted during labor and/or delivery.

Premature rupture of membranes (more than 12 hours)—Rupture of the membranes at any time during pregnancy and more than 12 hours before the onset of labor.

Abruptio placenta—Premature separation of a normally implanted placenta from the uterus.

Placenta previa—Implantation of the placenta over or near the internal opening of the cervix.

Other excessive bleeding—The loss of a significant amount of blood from conditions other than abruptio placenta or placenta previa.

Seizures during labor—Maternal seizures occurring during labor from any cause.

Precipitous labor (less than 3 hours)—Extremely rapid labor and delivery lasting less than 3 hours.

Prolonged labor (more than 20 hours)—Abnormally slow progress of labor lasting more than 20 hours.

Dysfunctional labor—Failure to progress in a normal pattern of labor.

Breech/Malpresentation—At birth, the presentation of the fetal buttocks rather than the head, or other malpresentation.

Cephalopelvic disproportion—The relationship of the size, presentation and position of the fetal head to the maternal pelvis which prevents dilation of the cervix and/or descent of the fetal head.

Cord prolapse—Premature expulsion of the umbilical cord in labor before the fetus is delivered.

Anesthetic complications—Any complication during labor and/or delivery brought on by an anesthetic agent or agents.

Fetal distress—Signs indicating fetal hypoxia (deficiency in amount of oxygen reaching fetal tissues).

Abnormal conditions of the newborn

Anemia—Hemoglobin level of less than 13.0 g/dL or a hematocrit of less than 39 percent.

Birth injury—Impairment of the infant's body function or structure due to adverse influences which occurred at birth.

Fetal alcohol syndrome—A syndrome of altered prenatal growth and development occurring in infants born of women who consumed excessive amounts of alcohol during pregnancy.

Hyaline membrane disease/RDS—A disorder primarily of prematurity, manifested clinically by respiratory distress and pathologically by pulmonary hyaline membranes and incomplete expansion of the lungs at birth.

Meconium aspiration syndrome—Aspiration of meconium by the fetus or newborn, affecting the lower respiratory system.

Assisted ventilation (less than 30 minutes)—A mechanical method of assisting respiration for newborns with respiratory failure.

Assisted ventilation (30 minutes or more)—Newborn placed on assisted ventilation for 30 minutes or longer.

Seizures—A seizure of any etiology.

Congenital anomalies of child

Anencephalus—Absence of the cerebral hemispheres.

Spina bifida/meningocele—Developmental anomaly characterized by defective closure of the bony encasement of the spinal cord, through which the cord and meninges may or may not protrude.

Hydrocephalus—Excessive accumulation of cerebrospinal fluid within the ventricles of the brain with consequent enlargement of the cranium.

Microcephalus—A significantly small head.

Other central nervous system anomalies—Other specified anomalies of the brain, spinal cord, and nervous system.

Heart malformations—Congenital anomalies of the heart.

Other circulatory/respiratory anomalies—Other specified anomalies of the circulatory and respiratory systems.

Rectal atresia/stenosis—Congenital absence, closure, or narrowing of the rectum.

Tracheo-esophageal fistula/esophageal atresia—An abnormal passage between the trachea and the esophagus; esophageal atresia is the congenital absence or closure of the esophagus.

Omphalocele/gastroschisis—An omphalocele is a protrusion of variable amounts of abdominal viscera from a midline defect at the base of the umbilicus. In gastroschisis, the abdominal viscera protrude through an abdominal wall defect, usually on the right side of the umbilical cord insertion.

Other gastrointestinal anomalies—Other specified congenital anomalies of the gastrointestinal system.

Malformed genitalia—Congenital anomalies of the reproductive organs.

Renal agenesis—One or both kidneys are completely absent.

Other urogenital anomalies—Other specified congenital anomalies of the organs concerned in the production and excretion of urine, together with organs of reproduction.

Cleft lip/palate—Cleft lip is a fissure or elongated opening of the lip; cleft

palate is a fissure in the roof of the mouth. These are failures of embryonic development.

Polydactyly/syndactyly/adactyly—Polydactyly is the presence of more than five digits on either hands and/or feet; syndactyly is having fused or webbed fingers and/or toes; adactyly is the absence of fingers and/or toes.

Club foot—Deformities of the foot, which is twisted out of shape or position.

Diaphragmatic hernia—Herniation of the abdominal contents through the diaphragm into the thoracic cavity usually resulting in respiratory distress.

Other musculoskeletal/integumental anomalies—Other specified congenital anomalies of the muscles, skeleton, or skin.

Down's syndrome—The most common chromosomal defect with most cases resulting from an extra chromosome (trisomy 21).

Other chromosomal anomalies—All other chromosomal aberrations.

Related reports

Many of the topics discussed in this report are covered in more analytic detail in other reports published by NCHS. Topics of reports published in the past 5 years include twin births (87), triplet births (77), teenage birth rates by State (12), birth rates by educational attainment of the mother (31), cesarean deliveries (88), birth and fertility rates for States (89), births to unmarried mothers (27), characteristics of births in Asian or Pacific Islander population subgroups (24), and trends in pregnancies and pregnancy rates (18).

This report presents summary tabulations from the final natality statistics for 1995. The National Center for Health Statistics will respond to requests for unpublished data whenever possible.

Contents

Abstract	1	Births to unmarried women	7	Attendant at birth and place of delivery	14
Highlights	1	Age of father	9	Method of delivery	14
Introduction	2	Educational attainment	9	Infant health characteristics	15
Methods	3	Maternal lifestyle and health characteristics	9	Period of gestation	15
Results and discussion	3	Weight gain	9	Birthweight	15
Demographic characteristics	3	Medical risk factors	10	Apgar score	17
Births and birth rates	3	Tobacco use during pregnancy	11	Abnormal conditions of the newborn	17
Age of mother	3	Alcohol use during pregnancy	12	Congenital anomalies	17
Live-birth order	5	Medical services utilization	12	Multiple births	18
Race	5	Prenatal care	12	References	18
Hispanic origin	5	Obstetric procedures	13	List of tables	21
Total fertility rate	6	Complications of labor and/or delivery	13	Guide to tables	23
Births by State	6			Technical notes	76
Sex ratio	6				
Month of birth	7				
Day of week of birth	7
