

Researchers reveal parsec-scale radio emission properties of dual AGNs by multi-phase-center VLBI observations

July 17 2024, by Liu Jia

Naturally weighted VLBA 5 GHz images (side columns) and VLA C-band

images (middle column) of the target sources. The white circle in the center of the image provides the angular scale of the Gaussian fitting, and the beam is shown in the bottom left corner. Credit: *The Astrophysical Journal* (2024). DOI: 10.3847/1538-4357/ad463b

Galaxy mergers play a crucial role in the cosmological evolution of galaxies. During galaxy merging, tidal torques can trigger the accretion and feedback of the central black holes in merging galaxies, forming dual active galactic nuclei (AGNs).

However, such confirmed dual-AGN instances are quite rare currently. Further merging of dual AGNs could form supermassive black hole binaries, which are important sources of low-frequency gravitational waves in the universe.

Studying the emission properties of dual AGNs not only helps to understand [galaxy mergers](#) and evolution but also plays an important role in the advancement of multi-messenger astronomy.

In a recent study [published](#) in *The Astrophysical Journal*, Xu Wancheng, a graduate student supervised by Prof. Cui Lang and Prof. Liu Xiang from the Xinjiang Astronomical Observatory (XAO) of the Chinese Academy of Sciences, along with the collaborators, conducted phase-referenced observations using the Very Long Baseline Array (VLBA) at 5 GHz on four confirmed radio-selected dual AGNs in Stripe 82 region.

The researchers obtained high-resolution radio images of eight sub-sources in the four dual AGNs based on multi-phase-center technique, and successfully detected two compact radio cores corresponding to J0051+0020B and J2300-0005A.

These two sub-sources exhibited high brightness temperature ($>10^6$ K) and radio emission power ($>10^{21}$ W/Hz), showing typical characteristics of compact radio jets. The other six components were not detected by VLBA and their 5 GHz radio emission was resolved out in the high-resolution images.

Based on the VLBA observations and multi-band properties such as optical and X-ray data of target sources, the researchers analyzed the 5 GHz radio emission origins of each component in the four dual AGNs, and studied the differences between dual AGNs and isolated AGNs.

The findings supported the feasibility and advantages of wide-field Very Long Baseline Interferometry (VLBI), a potent tool for high-resolution imaging and precise astrometric measurements, in determining the positions of black holes in dual AGNs and characterizing their compact radio emissions.

Through multiband observations, the four [radio](#)-selected dual AGNs in Stripe 82 region were confirmed. In addition, the multiband and multiscale observational studies on rare and reliable dual-AGN sources help to reveal the complex process of galaxy mergers.

This study provides valuable insights into future in-depth analyses and discussions on [observational studies](#) of larger dual-AGN samples.
